The universal lament as to trade depression has not failed to produce a marked diminution in the amount contributed in this honoured custom; still there is reason to be satisfied that it is not less, and that the spirit of liberality exists among those who are willing to give to the best of their means. An excuse of any kind is often sufficient to retard the flow of charity, and when one can see so much expended in holidays and amusements of all kinds, it is reasonable to infer that, however bad the commercial aspect of affairs may be, there is still a sum left for enjoyment of a personal kind, a little self-denial in which would present a serious difference to our charities. The amount of the collections this year, which go to the General Hospital, up to the present time is £3931 1*s.* 11*d.*

QUEEN'S COLLEGE.

At a recent meeting of the Council of this College the Home Secretary was elected a member of the Council. In view of prospective legislation on the foundation of a central university in the midlands, this appointment may be looked upon with much satisfaction. It is singular to note in a town which boasts of progress in educational and political matters that no exception was taken to the fact that the Home Secretary belongs to the Roman Catholic faith. The time has passed for differences of this nature to affect the governing body of an [illegible] institution, and though the College possesses a theological faculty it is sufficiently guarded by common sense and numbers to prevent any undue influence of the kind suggested entering into its administration.

THE MEDICAL SCHOOL.

A goodly number of fresh entries and an enthusiastic teaching staff gave a good augury for the session, which was commenced by a conversazione and distribution of prizes at the beginning of the month. The advantages are well received by the students, and the opportunities of study afforded by the amalgamation with the Mason Science College are recognised as being valuable elements of success.

THE MIDLAND MEDICAL SOCIETY, BIRMINGHAM.

On Wednesday, the 3rd inst., the annual meeting of this Society was held at the Grand Hotel, under the presidency of Mr. Lloyd Owen. An address was given by Mr. Thomas Bryant on the value of exploratory operations in the practice of surgery, which was listened to by a large and appreciative audience. Mr. Bryant spoke of such operations being justifiable when they lead on to treatment, and instanced their particular value in diseases of the breast and testis. In regional surgery, and especially with regard to the question of hernia, intestinal strangulation and obstruction, he quoted cases, and gave deductions from his own experience, to mark the importance of early recourse to surgical aid. A new method of performing colotomy in cases not requiring immediate relief was mentioned, namely, by transfixing the bowel with needles to the upper and lower margins of the wound, and opening some days later. On the motion of Mr. Oliver Pemberton, seconded by Mr. Bennett May, a vote of thanks was accorded to Mr. Bryant for his valuable and instructive address.

THE QUEEN'S HOSPITAL, BIRMINGHAM.

I regret to have to note the retirement of Mr. Furneaux Jordan from the active duties of his profession in connexion with the Queen's Hospital, Birmingham. At a meeting of the general committee held on the 2nd inst., the following resolution was passed: "That the committee receive with great regret the resignation of Mr. Furneaux Jordan, on account of ill-health, of the office of honorary surgeon which he has held for a period of twenty-three years (having previously held the office of assistant-surgeon for three years), in the course of which he has rendered very valuable services to the hospital, with equal distinction to himself, and has retained the entire confidence of the committee; and they trust that his retirement from professional work will materially conduce to the improvement of his health, and to the prolongation of his valuable life. The committee also hope that Mr. Furneaux Jordan will allow them to recommend him to the governors for election as consulting surgeon."

A GHOST.

The suburbs of Birmingham have lately been much excited by the presence of some appearance attributed to supernatural agencies in the form of a ghost. The application of ash or hazel in a solid form has been suggested as a remedy, and it is expected that the performer of this illusion will have a sorry time of it if met with by the masculine residents of the localities visited. In the meantime much perturbation is caused in the minds of the children and servants where these visitations have occurred.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

SUNDERLAND: INFANT MORTALITY AND THE FEEDING-BOTTLE.

IN his last report the medical officer of health, Mr. A. E. Harris, makes some pointed reference to infant mortality in the borough of Sunderland and the feeding-bottle, during the last quarter the deaths from diarrhœa being higher than usual. There were, he says, "no special local causes to account for this increase in the disease, which has been more than that usually prevalent in the kingdom. Nevertheless, it has been elicited that the greatest mortality occurred among children under twelve months old, who were fed from the bottle. Out of seventy-seven deaths of children of this age sixty were fed and seventeen suckled.'

lle also adds that, as regards the general health of the borough, there can be no doubt that the improved cleansing of the streets and ashpits has had a most beneficial and salutary effect. This is proved by the decline in the number of deaths from zymotic diseases, which he pointed out over three years ago would probably decrease with more efficient work, and that "what is true of the family is true of the town—that cleanliness begets health."

"IN THE ARMS OF MORPHEUS."

Some boys at Sunderland got a caution the other day likely to last them for some time. They stole from a chemist's a bottle of what they thought were cough lozenges; these they carried off as a great prize and distributed among their friends. The lozenges turned out to be morphia, and at least six of the boys fell into a profound sleep, and were awakened with some difficulty after a long time; they then felt what is termed "the after-damp" in mining districts—viz, sickness and headache.

THE VICTORIA HALL DISASTER.

It will be of interest to many to know that between £3000 and £4000 is invested with the corporation in connexion with the Victoria Hall (Sunderland) disaster, and that the interest of the fund is applied to sending children to convalescent homes. The fund is under the direction of a committee of management, and the children are recommended by the infirmary staff, the Children's Hospital, or by private practitioners. This is being done until such time as the committee of the fund are in a position to establish a convalescent home.

TYNE PORT SANITATION.

At the last meeting of the Tyne Port Sanitary Authority, it was shown that the work done by this authority during August and September included the inspection of 109 British steamers and 637 sailing vessels, 350 foreign steamers and 246 sailing vessels, including fishing vessels, steam and sail. There were 2627 inspections made, and sanitary defects corrected. The report showed that a great improvement had been noted in the crew spaces and closets on board the ships. At the same meeting the medical officer of health, Mr. H. E. Armstrong, presented a copy of the report of the Local Government Board, which says, as regards the Tyne: "The joint board of the Tyne affords a typical example of efficient administration. The authorities have established a well-organised staff for carrying out the duties of the port, including the medical officer of health, Mr. H. E. Armstrong, also appointed by the urban district, a master mariner as an inspector of nuisances, and two assistants, together with a steam launch, to facilitate boarding, and two floating isolated hospitals—viz., one for port purposes, which was supplemented in 1884 by a second for cholera cases." The report then goes on to speak of the new floating hospital of novel design, which has been described previously in these notes.

NEW ENTRIES.

It is stated that the number of new students who have entered at the College of Medicine here this session is 66 for the full curriculum, and the number who have entered for the required term of "residence" for the degree is 42.

THE TESTIMONIAL TO MR. R. G. GAMMAGE.

Mr. Gammage of Sunderland, having been compelled by ill-health to retire from practice, a purse, principally contributed by his professional friends and amounting to £86, has been handed to him on his departure to the south.

Newcastle-on-Tyne, Nov. 2nd.

IRELAND.

(From our own Correspondent.)

ACADEMY OF MEDICINE IN IRELAND.

The fourth annual general meeting of the Academy of Medicine in Ireland was held on the 29th ult., presided over by Dr. Robert McDonnell, F.R.S. The report was a satisfactory one, the income amounting to £844, and leaving a balance to credit of £392. The Council recommended a grant of one hundred guineas out of the funds of the Academy towards the expenses of the annual meeting of the British Medical Association in Dublin in 1887, which was agreed to, and the office-bearers for the various sections having been elected, the proceedings terminated. The opening address of the Surgical Section of the Academy will be given on the 13th inst. by Sir William Stokes, president of the Royal College of Surgeons in Ireland, when an interesting and eloquent discourse may confidently be expected.

ROYAL UNIVERSITY OF IRELAND.

The Senate at a meeting held last week elected several Fellows in various departments, among others Dr. Lynham, of the Queen's College, Galway, in the Department of Medicine. December 30th has been appointed for a meeting of Convocation to elect a member of Senate in the place of the Rev. Dr. Kavanagh, deceased. The degrees in the Faculty of Medicine obtained in the recent examinations were conferred at the Royal University on the 28th ult., Lord Emly, Vice Chancellor of the University presiding. At the meeting of Convocation held last week the proceedings were of a very noisy and unseemly character. The chief business transacted was the election of a member of the Senate, the result being that Dr. Whitla, of Belfast, was successful. It was generally believed that this would be the case, but it was not thought that his majority would have been so large.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

In the recent examination for the 3rd and 2nd Professional of this College, the rejections were extremely numerous, and in the latter, out of sixty-six candidates twenty were stopped at the *viva voce* alone. A supplementary examination, I am informed, will be held for the 3rd Professional in about three months, and probably for the 2nd and 1st Professional Examinations as well.

CORPORATION GRANTS TO DUBLIN HOSPITALS.

At a recent meeting of the Dublin Town Council the following sums were granted to various charitable institutions viz, £300 each to Jervis-street, City of Dublin, Meath, Sir P. Dun's, and Mercer's Hospitals. As sectarian feeling unhappily runs high in the Corporation of Dublin, two general hospitals obtained more liberal donations; thus the Mater Misericordiæ was granted £500, and St. Vincent's Hospital £400. In the same way the Coombe Lying-in Hospital got £500, the Rotundo Lying-in, with great difficulty, exactly half that amount, and the National Lying-in Hospital, £100. The other grants included £150 to Steevens's, £300 to Hospital for Incurables, £150 to St. Mark's, £160 to the National Eye Infirmary, £250 to the Children's Hospital, and £100 each to the two Orthopædic institutions.

CITY OF DUBLIN HOSPITAL.

I had an opportunity on the 28th ult. of seeing at this hospital some interesting cases recently operated on by Mr. Wheeler, among others a patient from whom the previous week a calculus had been removed, which measured three inches in length by five-eighths of an inch in width. The patient had a slight attack of cystitis, but was doing remarkably well. The same morning two operations were performed by Mr. Wheeler in the theatre of the hospital. The first was the radical cure of varicocele, the left side being engaged. Mr. Wheeler dissected down to the affected parts, and tied the veins above and below, removing pieces of the veins. The second operation was the removal of a tumour (apparently fibro-cartilaginous in its nature) from the parotid region, which had been growing for the past three years. The tumour was about the size of a pigeon's egg, and was very tedious and troublesome to remove, in consequence of its position, and the manner in which it was bound down by fascia.

ARTERIAL ANOMALY.

There was last week in a subject in the dissecting-room of the Ledwich School of Medicine, Dublin, an example of a comparatively rare anomaly. The right subclavian artery came off from the arch of the aorta, and the right common carotid also took its origin from the arch. Practically there was no arteria innominata. The two carotids at their origin were barely separated. Excluding the coronary arteries, there were four branches from the arch of the aorta.

THE MEATH HOSPITAL.

The introductory lecture was given on Monday by Mr. Ormsby, and the annual dinner took place the same evening at the Shelbourne Hotel, presided over by Sir William Stokes, president of the Royal College of Surgeons.

Dublin, Nov. 2nd.

PARIS.

(From our own Correspondent.)

M. PASTEUR'S INOCULATIONS.

In a recent series of experiments to test the value of M. Pasteur's prophylaxis of rabies, Professor Frisch, of Vienna, inoculated sixteen rabbits by trephining. The virus used was of the third generation—that is, had evoluted in the organisms of three rabbits. Fifteen were subjected to preservative injections, one being set aside for comparison, but they all became rabid on the sixteenth day, and died on the twenty-first. Six other animals were inoculated with a preparation of the cervical medulla from a mad dog, but instead of trephinings, the virus was injected hypodermically. Three of these were subjected to preventive treatment, and the others kept as a test. None of these six animals became rabid. These experiments would seem to show (1) that rabies can be determined absolutely by inoculations of the nervous centres, in which case the preservative treatment is inefficacious; (2) that when the virus is introduced by the skin rabies does not necessarily follow. These statements have elicited a further communication on the subject from M. Pasteur. Upon examining, says M. Pasteur, the histories of those cases in which death has occurred from rabies after the preventive inoculation, it will be found that most of the victims were children who had been bitten severely about the face. In these cases the original treatment may not be sufficient, and it is now recommended that the inoculation should be hastened, in order to arrive quickly at the strongest cultures. The first day, for instance, the medullæ of twelve, ten, and eight days should be inoculated, at eleven, four, and nine o'clock. The second day those of six, four, and two days, at the same hours. The third day that of one day. The treatment is resumed on the fourth day by inoculations of eight, six, and four days. The fifth day by those of three and two days. The sixth by that of one day. On the seventh the marrow of four days; on the eighth that of three days; the ninth of two days; the tenth that of one day. Three treatments are thus made in the course of ten days, each terminating in the inoculation of the freshest virus. M. Pasteur adds, that when the wounds are not cicatrised, and when the patients have delayed, these treatments may be renewed, with intervals of a few days, for four or five weeks, and when the wounds are severe. The whole "intensive" treatment, as he terms it, may be employed in one day. M. Pasteur has submitted ten children who were bitten on the head or face during the month of August to this new plan of treatment, and he asserts that it is also efficacious after intra cranial inoculation of the nervous centres of animals where the slower method fails. It will be interesting to hear what Professor Frisch thinks of the modified method. In the meantime M. Pasteur enjoyed an ovation at the Academy of Sciences, where he was complimented by the president, who begged him to persevere in his researches without being discouraged by hostile criticism. "Go ahead," said M. Jurien de la Gravière, "and the whole Academy will uphold you in your triumphal progress." At the Academy of Medicine M. Pasteur gave a second reading of this communication, and evoked expressions of the greatest satisfaction from M. Verneuil, who is, if I may be excused the expression, in the same line of business. "To-day's communication," said the eminent professor, "has done ample justice to these dark doings (the criticisms of the incredulous). M. Pasteur can henceforth advance in the path of progress without heeding his obscure critics!"

THE FRENCH SURGICAL CONGRESS.

The French Congress of Surgery continued its sittings during the remainder of October. M. Gross of Nancy related a case of cystotomy for the extraction of a hair-pin from the bladder of a young girl. He went on to say that there were two conditions in children which rendered the supra-pubic operation advisable—the elongated form of the bladder, and the high position of the peritoneal cul-de-sac, —so that the distension of the rectum is not necessary, although some elevation may be gained by it. M. Chenieux of Limoges condemned the practice of drainage in antiseptic surgery, and found a supporter in M. Mollière of Lyons. All wounds, however large, if placed in exact apposition and rendered aseptic by non-irritant agents should heal by first intention, which is impossible where there is a drainage-tube. Even in ovariotomy, hysterectomy, and similar operations, drainage is the reverse of useful. As long as the liquids exuded are thoroughly aseptic, it is better that they should be kept in a closed cavity, where their function is analogous to the effusions occurring at the seats of fractures. M. Chenieux considers, moreover, that when the patient is in a state of prostration this exudation forms a reserve fund which can be drawn upon by absorption for the first few days, whilst alimentation is insufficient. The discussion on nephrotomy and nephrectomy brought forward a number of eminent speakers. M. Le Dentu began by remarking that the indications and contra-indications of nephrectomy had been well summed up by Gross of Philadelphia. The kidney should be removed in sarcoma of the adult, non-malignant neoplasms, in the early stage of tubercular disease, and in fistulæ and rupture of the ureter. It is formally contra-indicated in sarcoma of children, cancer, and advanced tubercle. In other cases, such as floating kidney, hydro-nephrosis, suppuration, and calculus, nephrotomy or nephrectomy may be resorted to according to circumstances. The incision should be transverse or oblique, and not too large, and resection of the last rib should not be practised. Transperitoneal nephrectomy should only be employed in exceptional cases, as the front of the kidney may be reached, as Thoruton has shown, from behind, without cutting the peritoneum. M. Lucas-Championnière, Bouilly, Reliquet, Demons, and Malherbe communicated their experience of the two operations. M. Ollier of Lyons stated that a modification of the operation of nephrotomy, as first practised by himself, was preferable to that usually adopted. Except in cases of sarcoma and malignant disease, he enucleated the kidney from its capsule. The risk of peritoneal injury is avoided, and there is much less hæmorrhage. As regards incisions, he differs entirely from M. Le Dentu. Their form is immaterial, and their length causes him no anxiety. He has made some of thirty-four centimetres (over twelve inches). He does not hesitate to remove a rib, or even two if necessary. M. Pean gave his experience of the two operations, and stated that he would perform nephrectomy in localised cancer of the kidney where the general health is satisfactory. He prefers the lumbar operation, but does not fear to reach the kidney by the abdomen when expedient. In 1884 he removed an enormous cancer by gastrotomy, the abdominal wall being incised in the middle line. The peritoneum was sutured in front of the cavity left by the ablation of the tumour, and the abdomen then closed. The patient is now in perfect health.

TREATMENT OF PHTHISIS.

The introduction of sulphuretted hydrogen into the respiratory passages by breathing gives rise to various disturbances, which may terminate, when a sufficient amount is taken, in death; but it was shown by Claude Bernard that when absorbed by the rectum an almost indefinite quantity may be eliminated by the lungs without harm. Dr. Bergeon, of the Faculty of Lyons, has been experimenting on the action of gaseous enemata for some time, and finds them useful in a variety of diseases depending upon the presence of micro-organisms. The practical point was to find a suitable vehicle for the administration of the sulphuretted hydrogen which should at the same time be without danger to the economy and easily tolerated by the bowel. It is said that carbonic acid fulfils these conditions. It is easily tolerated by the large intestine. It is rapidly absorbed, and is eliminated by the lungs with the medicinal gas it contains. It has, moreover, a therapeutic action itself, which may be the chief factor of this new treatment. Dr. Bergeon states that those who have tried this method in Paris, Lyons, Geneva, and Marseilles, in cases of phthisis, have generally observed a rapid disappearance of the suppuration, with progressive improvement. Expectoration has ceased, and the only stethoscopic signs remaining are of a dry character, and due to cavities and cicatrices. In the last three months the treatment has been tried at the Hôpital St. Antoine. In two cases of asthma, an injection of carbonic acid, charged with sulphydric acid, was made half an hour after admission. The dyspnœa was decreased considerably, and the treatment being continued, the respiration became free, and the attacks did not recur during the treatment. Nine cases of pulmonary phthisis, presenting

general and physical signs of the disease, together with bacilli, were treated in the same manner. Cough and expectoration were greatly diminished, and the increase in weight was rapid—from one to two pounds a week, amounting in one instance to nine pounds in six weeks. The bacilli, however, did not disappear from the sputa. Dr. Bergeon recommends his method in phthisis, asthma, whooping-cough, inflammation, bronchiectasis, bronchorrhœa, and pulmonary catarrh. He insists upon the greatest care in its application. The CO_2 should be absolutely pure, and prepared by the action of sulphuric acid on bicarbonate of soda. The recipient should be perfectly free from air, and great care should be taken to prevent the entrance of air at any part of the tube, its introduction into the bowel even in minute quantities being said to cause meteorism and enteralgia. Four or five litres of CO_2 charged with sulphuretted hydrogen are sufficient for an injection, which should be repeated twice daily, care being taken not to administer the gas within three hours after a meal. As regards the *modus operandi*, two very important instruments for the production of the gas and its subsequent sulphydration are figured in the *Bulletin de l'Académie de Médecine*, but practically the two points seem to be the introduction of the pure CO_2 into a five-litre bag without admixture with air, and its passage through a sulphureous solution before entrance into the bowel. Those who possess a thermo-cautère will find that, with a little ingenuity, nothing but a bag to hold the CO_2 is necessary beyond the apparatus which works the cautery. The bag being adapted to the aspirating ball of the thermo-cautère by means of an indiarubber tube, which may be kept closed by a clip instead of the more expensive tap, a rectum tube is substituted at the other end for the cautery. The bottle of the thermo-cautère being replaced by a more capacious jar holding a pint of sulphydric solution in its lower half, and leaving room for the gas above, the apparatus is complete. Upon removing the clip between the bag and the ball, and working the latter, the CO_2 is aspirated and forced through the solution, where it becomes charged with sulphuretted hydrogen, and then passes on to the bowel. I may mention in this connexion that various anti-microbic treatments are being carried out in the Paris hospitals. At Laennec they are using hypodermic injections of eucalyptol, as proposed by Dr. Roussel, who claims that the bacilli are thus destroyed. In the majority of cases this has not been observed, but in one instance, which will probably be communicated to the Academy shortly, the micro-organisms, which were abundant in the sputa on admission, disappeared under treatment. Dr. Filleau claims to obtain a similar result by the use of a 1 per cent. solution of carbolic acid, of which he injects a hundred drops at each operation. No local irritation of any importance follows, if the carbolic acid is chemically pure, in the form of silky crystals. Iodoform increases daily in favour, especially where there is hypersecretion.

Paris, Nov. 1st.

THE SERVICES.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Surgeon John O'Callaghan has been placed on the retired list of his rank.

The following appointments have been made:—Fleet Surgeon Thomas H. Atkinson to the *Brilliant*, temporary; Staff Surgeon Frederick M'Clement to the *Active*; Staff Surgeon John Tyndall, to the *Revenge*; Surgeon C. B. D'E. Chamberlain, to the *Asia*; Surgeon J. E. Fogerty, to the *Excellent*; Surgeons R. Hickson and John Lowry, to the Plymouth Hospital; and Surgeons G. D. Trevor-Roper and Octavius S. Fisher, to the *Impregnable*.

RIFLE VOLUNTEERS.—16th Middlesex (London Irish): Acting Surgeon H. R. H. Bigg, from the 22nd Middlesex (Central London Rangers), to be Surgeon.

HOSPITAL SATURDAY FUND.—At a meeting of the Board of Delegates of this fund held on the 30th ult., it was reported that the collection now reached, after payment of all expenses, £8500. It is anticipated that before the close of the fund for the present year (30th inst.) some £2000 or £3000 more will be paid in by those subscribers who have not yet made their annual return. Of the amount now in hand £4000 was realised by the ladies' out-door collection in July.

MEETING OF FELLOWS & MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

A GENERAL meeting of the Fellows and Members was held in the theatre of the College of Surgeons on Thursday afternoon last, to receive a report from the Council of their transactions during the past collegiate year. There was a large attendance both of Fellows and Members, showing an undiminished interest in the questions of reform now agitating the College. As will be seen from the following abstract of the proceedings, a full report of which will be published in our next issue, speakers, both Fellows and Members, were, with one exception, unanimous in recommending the adoption of the resolutions which were put from the chair. The exception was Mr. Erichsen, who has hitherto always posed as a friend of reform, and was recently a candidate for Parliament in the Liberal interest for the University of Edinburgh. Mr. Rivington's speech lost much of its force by being too long, and by the persistency with which he disregarded the evident impatience of the meeting.

After a few opening remarks from the President, Mr. W. S. Savory, Mr. Timothy Holmes moved: "That in the opinion of this meeting it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education, (1) if Members of the College were empowered to take part (separately or conjointly with the Fellows) in the election of members of the Council; (2) if Members of the College were eligible to sit in the Council, provided (*a*) that no Member of the College shall be entitled to vote till he have been such member for a period of ten years; (*b*) that no Member of the College shall be eligible to sit in the Council till he have been such member for a period of twenty years; and (*c*) that not more than one-fourth of the Council shall consist of Members of the College who are not also Fellows."

The motion was seconded by Dr. Danford Thomas. It was opposed by Mr. Erichsen, and supported by Mr. Marshall and Mr. Rivington. On being put to the meeting it was carried by a very large majority, only a few hands being held up against it.

The following motion was proposed by Dr. Ralph Gooding, seconded by Mr. John Tweedy, and agreed to: "That with a view to give effect to the recommendation in the foregoing resolution, the Council is hereby respectfully requested to empower certain members of its body to meet and confer with representatives of the Association of Fellows and of the Association of Members, together with, if necessary, an equal number of Fellows and Members who may not belong to either of the Associations, to be selected in any manner satisfactory to the Council."

On the motion of Dr. F. F. Alderson, seconded by Dr. Burgess, it was resolved: "That with reference to the report from Mr. John Marshall, on page 15 of the Council's report, this meeting requests the Council of the College to consider the advisability of accepting an arrangement for combination with the Apothecaries' Society, as well as the College of Physicians, for the purposes of conjoint examinations for medical diplomas in England and Wales, under the Medical Act of 1886, and to report thereon at a future meeting of Fellows and Members, to be summoned for the purpose at an early date."

It was then moved by Mr. Willett, and seconded by Mr. R. Davy: "That, in the opinion of this meeting, the method recommended by the Council for widening the basis upon which the Fellowship is obtained tends to lower the academic status of that diploma, and, in the interest of surgical education, is not advisable."

To this an amendment was moved by Mr. W. Steel, and seconded by Mr. Ashton Ellis, that the word "first" be inserted in the resolution before the word "method." The amendment was carried by a small majority, and the motion thus amended was carried as a substantive resolution.

Obituary.

DR. JOSEPH E. MILLER, J.P.

AFTER a brief illness the subject of this notice passed away last Sunday, at his city residence in Derry, at a very advanced age. Dr. Miller for some time past had been in delicate health, but serious symptoms did not supervene until about eight days since. The deceased was in his ninety-fourth year, and belonged to a family remarkable for their longevity, several near relatives having attained to upwards of ninety years of age. He was in extensive practice in Derry for sixty-nine years, where he held a leading position, and filled many civic offices with credit, including that of Mayor, to which he was repeatedly appointed; and on his retirement from the Corporation he was presented with a handsome piece of plate, in recognition of his public services. The son of a Presbyterian minister, Dr. Miller graduated in Edinburgh in 1815, and commenced the practice of his profession in Derry two years afterwards. During the epidemic of cholera in that city in 1832, and the famine fever of 1847, his exertions on behalf of those attacked were unceasing, and his treatment eminently successful. In 1824 he married a daughter of Dr. Scott, of Derry, and leaves one son—viz., Sir Wm. Miller, M.B., J.P., the well-known surgeon to the City and County Derry Infirmary.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members on Oct. 28th:

Bury, Judson Sykes, M.D. Lond., Manchester.
Hogben, Edgar, M.B. Dub., Birmingham.
Mackenzie, Hector William Gavin, M.B. Camb., St. Thomas's Hospital.
Mott, Frederick Walker, M.B. Lond., Harrow.
Philpot, Joseph Henry, M.D. Lond., South Eaton-place.
Wethered, Frank Joseph, M.B. Lond., Chest Hospital, City-road.

The following gentlemen were admitted Licentiates on Oct. 28th:

Abbott, William Louis, Guy's Hospital.
Armstrong, George Samuel, Burton-crescent.
Ayres, Charles James, Grosvenor-road.
Baker, William Henry, Offerton-road.
Barrett, Ernest, St. Bartholomew's Hospital.
Bell, George Craigie, Eden Villa, Leytonstone.
Biddlecombe, Edward Henry, North Allington, Bridport.
Bigelow, Arthur Wellington, Burton-crescent.
Blackler, Henry John, Knight's-hill, West Norwood.
Blakeney, John H., Jaffray Hospital, Gravelly-hill, Birmingham.
Boase, Richard Davey, Headland-park, Plymouth.
Böhrsmann, Matthias Christian Robert, Sydney, N.S.W.
Bowden, Walter, Hilldrop-crescent, Camden-town.
Brown, Charles, Baskerville-road.
Caven, John, Burton-crescent.
Chaldecott, John Henry, St. Paul's-road, Camden-square.
Christopherson, Cecil, North-West Hospital, Kentish-town-road.
Clarke, Walter James, Brvanston-street.
Colborne, William John, Birdhurst-road, New Wandsworth.
Crawford, Gustavus Rochford Jarvis, New Brunswick, Canada.
Darrell, Harrington Wyndham, Burton-crescent.
Davis, William, Evelyn-street, Deptford.
De Nysen, Petrus Johannes, Portsdown-road, Maida Vale.
Dewes, Frederick Joseph, South Lambeth-road.
Dreaper, Wm. Grey, Richmond-hill, Old Trafford, Manchester.
Dwyer, Hubert De Burgh, Argyll-road.
Edsell, George Alfred, Beulah-hill.
Edwards, Percy, Western General Dispensary, Marylebone-road.
Gidley, Gustavus George, Honiton.
Gledden, Alfred Maitland, Helensles, Hornsey-lane.
Goodall, Edwin, Guy's Hospital,
Goose, William, Oakley-square.
Halliwell, Thomas, Malpas-road, Brockley.
Halstead, George Ezra, Water-lane, Brixton.
Halsted, Harold Cecil, Gore-road.
Hamilton, Herbert James, Burton-crescent.
Harris, Clayton Campbell, Craven-road, Paddington.
Haultain, Charles Selby, Endsleigh-street, Tavistock-square.
Hill, Charles Marshall, Granville-square.
Honey, Thomas E., Westbourne-park-crescent, Harrow-road.
Honsberger, Jerome, Burton-crescent.
Hood, Frederick Colton, Gloster-place, Portman-square.
Horner, Charles Julian, Fern-hill, Walthamstow.
Ingleby-Mackenzie, Kenneth Walter, Guildford-street.
Jones, David Ogden, Gloster-place, Portman-square.
Kelsall, Charles James Seddon, Talbot-road, Bayswater.
Lambert, Frederick Samuel, Station-road, Redhill.
Leeming, John, Burton-crescent.
Lipscomb, Eustace Henry, Trinity-square.
Macevoy, Henry John, Camden-road, Holloway.
McNair, George, Thurlow-hill, Dulwich.
Manson, Magnus Olaf, Romola-road.
Manton, John Albert, South-parade, Wakefield.
Millar, Lindsay Flagg, Ontario, Canada.
Mortlock, Charles, Ladbroke-gardens, Notting-hill.
Moyle, Walter Henry, Helston.
Mugford, Sidney Arthur, Sisters-avenue, Wandsworth.
Nowell, Barnes, Halliford House, Sunbury.
Parker, William, Dempsey-street, Stepney.
Parry, William Thomas, Burton-crescent.
Pearson, Henry Aked, Sale, Manchester.
Pearson, Richard, Durham-terrace, Westbourne-park.
Pockett, Lewis Walter, Gibson-square, Islington.
Popert, Alfred William, Beverley-road, Anerley.
Powell, Frederick Hamilton, Bernard-street.
Prall, Samuel Esmond, Forteus-road, Kentish-town.
Raymond, George Howard, New Brunswick, Canada.

Kendrick, Alfred, Nugent-road, St. John's-wood.
Ludbrook, Frederick Milner, Shalcombe-street, West Brompton.
Moore, Henry John, Charing-cross Hospital.
Pattinson, Charles Augustine, Archway-road, Highgate.
Smith, John Percy, Smith-street, Chelsea.
Tubbs, John Arthur Seymour, Old Steine, Brighton.
Williams, Herbert, Talgarth-road, West Kensington.
Woodhouse, Joseph, Camden-road, Oakley-square.

[In the list of Members published last week Mr. Edward C. Kingsford should have been described as of Upper Clapton, not "Clapham-common."]

UNIVERSITY OF CAMBRIDGE.—At a congregation held on Oct. 28th, Dr. Octavius Sturges was appointed Assessor to the Regius Professor of Physic during the current academical year. The following degrees were also conferred:

BACHELORS OF MEDICINE.—Walter Malden, Robert Chambers Priestly, E. Duguid Ritchie, Trinity; Fredk. Cecil H. Piggott, Emmanuel.
BACHELORS OF SURGERY.—Edward Duguid Ritchie, Trinity; Frederick Cecil H. Piggott, Emmanuel.

UNIVERSITY OF DURHAM.—On the 26th ult. the degree of M.D. was conferred on

Frederick M. Cook, M.B., M.S.

(Not "Imcock," as misprinted in our last issue.)

ROYAL UNIVERSITY OF IRELAND.—The following degrees in the Faculty of Medicine were conferred last week by Lord Emly, Vice-Chancellor of the University:—

BACHELOR OF MEDICINE.—Exhibitions (Second-class), £25 each: George S. Thomson, John R. Conner, John A. Keogh. Honours (Second-class): George S. Thomson, John Conner, John Keogh. Upper Pass: Samuel R. Collier, Frederick J. Crawford, Thomas Lusk, Francis L. Sealy, Edmund Woods. Pass: John Boyd, Robert Boyd, Patrick J. Burke, Timothy Corkery, Charles F. Daly, Denis J. Flynn, George Fuller, Howard J. Gahagan, John F. Gordon, Edward Griffin, William B. Hayes, John W. Irwin, James Johnston, David Junk, Charles R. Leader, William M. Lewis, Matthew

McAulay, James McMaster, Edward McSherry, James Mangan, Alexander P. Mooney, Charles Morgan, Michael Murphy, Frank Murray, Wm. J. Niall, Daniel O. Mahony, Timothy O'Riordan, Edward O'Sullivan, William Patterson, Henry Pillow, Edward Robinson, Richard Spencer, William Steen, Alexander Stevenson, John Thomas, George Vance, Eaton Waters, Michael Williams, James Williamson, Alleyn Wolfe.

MASTER OF SURGERY.—Honours (First-class): George Thomson, Andrew Buchanan; (Second-class) James D. Williamson, Frederick Crawford, Alleyn Wolfe. Pass: Arthur Atock, John Attridge, John Boyd, Robert Boyd, George Browne, Patrick Burke, Samuel Collier, John Connor, Timothy Corkery, Denis Flynn, George Fuller, Edward Griffin, William Hayes, John Keogh, Daniel Lane, Charles Leader, Lyncus Lyttle, Matthew McAulay, Edward McSherry, Wm. Milligan, Alex. Mooney, M. J. Murphy, Frank Murray, Wm. Niall, T. O'Riordan, B. O'Sullivan, W. Patterson, H. Pillow, E. Robinson, M. Robinson, R. Spencer, W. Steen, J. Tobin, G. Vance, Eaton Waters, Michael P. Williams, Edmund Woods.

MASTER OF OBSTETRICS.—Honours (First-class): George Thomson; (Second-class) S. R. Collier. Pass: P. J. Burke, John Connor, F. Crawford, C. F. Daly, Howard Gunagan, David Junk, John Keogh, Charles F. Knight, Daniel Lane, Thomas Lusk, E. McSherry, A. P. Mooney, M. J. Murphy, J. O'Connor, R. H. Spencer, A. K. Stevenson, J. C. Thomas, J. D. Williamson, Edmund McN. Woods.

The Dr. Henry Hutchinson Stewart Medical Scholarship, which is tenable for three years, was awarded to John W. Wolfe.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine; Surgery, and Midwifery, and received certificates to practise, on Thursday, Oct. 21st:—

Jones, John, Kilsane, Stanhope-road, Streatham.

Passed on Oct. 28th:

Darlow, Alfred, Plasket, Essex.
Gibbard, Thomas Wykes, Strixton, near Wellingborough.
Oliver, Francis G., M.R.C.S., L.R.C.P., Sunningside, Tunbridge.
O'Reilly, George Hartley, Wyndham House, Crescent-road, Reading.
Pedley, George Aston, The Terrace, Camberwell.
Redman, Wm. Edward, Vicarage-terrace, Nensden.
Williamson, Charles Fredk., M.R.C.S., L.R.C.P., Mildmay-park.
Young, Jr. Weekes, St. John's Villas, St. John's-road, Penge.

THE local Hospital Saturday Committee have just handed over to the Coventry and Warwickshire Hospital £660 as the result of their appeal for the current year.

THE death from blood-poisoning of Mr. Charlton, a well-known and highly-respected surgeon of Brabourne, is announced.

THE new water-supply for Stratford-on-Avon was formally inaugurated on the 27th ult. It is a gravitation scheme, and has cost £22,000 in execution.

A COMMITTEE was appointed at a meeting of the Bournemouth Commissioners on the 2nd inst. to consider a proposal to commemorate the jubilee year by the erection of a hospital, to be called the Victoria Hospital, or some such institute, in the centre of the town.

BRADFORD INFIRMARY.—The late Sir Henry Edwards left a legacy of £1000 for this charity, and Lady Edwards has contributed £750 for furnishing and endowing a children's cot in the same institution, in memory of her late husband.

ON the 28th ult., a woman was summoned at the Clerkenwell police-court, at the instance of the St. Pancras Vestry, for allowing her grandchild, while suffering from scarlet fever, to be exposed in the public thoroughfares. A fine of 10*s.* was imposed.

GUY'S HOSPITAL UNIVERSITIES' CLUB DINNER.—This dinner will be held at the Holborn Restaurant, at 7.30 P.M., on Nov. 22nd, Dr. Brailey in the chair. Mr. A. S. Taylor, of Guy's Hospital, will receive the names of Guy's men, being members of Oxford or Cambridge Universities (colleges and degrees should be stated), wishing to attend.

A LECTURE on "Transfusion for Hæmorrhage in Military Surgery" was delivered on the 28th ult., at the Medical Staff Mess, Woolwich, by Mr. C. E. Jennings, F.R.C.S. The lecture was followed by an interesting discussion, in which Sir T. Crawford, the Director-General, who presided, and several other officers, took part.

ST. JOHN AMBULANCE ASSOCIATION.—The annual report of this Association has just been issued. It states that during the past twelve months 11,703 "first aid" certificates and 1635 "nursing" certificates have been awarded, whilst the total number of medallions which have been granted up to the present time is 5130. These figures show a substantial and satisfactory increase in results, and the report, taken as a whole, must afford great encouragement to those interested in extending the knowledge of "first aid" and "nursing."

VACCINATION GRANT.—Dr. Merlin, of the Sutton district of the Ely Union, has received a Government gratuity for the fifth time for efficient vaccination.

CARDIFF WATER-SUPPLY.—On the 28th ult., the Llanishen Waterworks, having a capacity of 317,000,000 gallons, were formally opened by Mr. Alfred Thomas, M.P. The new works, which have been in progress since 1878, are required for the town of Cardiff, and the water stored in the reservoirs has its original source in the Brecon Hills.

DONCASTER INFIRMARY.—At the annual meeting of the governors of, and subscribers to, this institution on the 28th ult., it was reported that the number of in-patients admitted during the year was 192, and that 2800 out-patients had been treated. The expenditure amounted to £1444, the income exceeding this sum by about £250.

DEATH FROM CHLOROFORM.—An inquest was held on the 27th ult. at the Huddersfield Infirmary on the body of a boy aged four years, who died in the institution on the previous day while under the influence of chloroform. The jury found that the cause of death was sudden failure of the heart's action, and expressed the opinion that the chloroform was duly and properly administered.

WALLASEY MEDICAL CHARITIES.—The first lecture of a course to be delivered in aid of the Wallasey medical charities was given on the 28th ult. by Mr. H. M. Stanley, the famous African explorer, on the subject "My African Travels and work." By a similar course of lectures last year, £60 was placed at the disposal of the various charities.

THE death is announced, in the seventy-fourth year of his age, of Mr. Thomas Middleton, a formerly well-known medical practitioner in Salford. The deceased was born in 1813, commenced practice in 1834, and in 1852 was elected a Fellow of the Royal College of Surgeons. After his retirement from the active practice of his profession, Mr. Middleton resided at Didsbury, where his death occurred.

BRISTOL DISPENSARY.—For many years past considerable inconvenience has been experienced in consequence of the increasing work in the different departments of this institution having outgrown the accommodation afforded by the old building, which has for a long period been the headquarters of the dispensary, and the committee have therefore decided upon the erection of new premises, the first section of which is now in progress. The estimated cost of the new building is £6000.

PORT SAID BRITISH HOSPITAL.—The hospital building to be erected at Port Said on land granted by the Suez Canal Company, is now ready, and will be shipped to Egypt in a few days. It is a commodious, airy structure of one storey, containing two wings, one on each side of an open passage, united under one roof at the entrance. At present the hospital is planned to contain 30 beds, but more patients could be accommodated on an emergency. In all there are five wards, the principal of which is 38 ft. long by 28 ft. wide, and the average height of the various apartments is 10 ft. to the eaves, or 19 ft. to the top of the ridge. The whole of the building stands on a frame, which will rest on concrete pillars 4 ft. above the ground, so as to allow of a free draught of air underneath. The hospital, which occupies about half an acre of ground, is built with Baltic fir, and its construction has cost about £3000.

ACADEMY OF MEDICINE IN IRELAND.—The following office-bearers have been elected for the ensuing year:—Medical Section (Council): J. Little (President), W. Beatty, M. Boyd, J. Magee Finny, T. Grimshaw, R. A. Hayes, H. Kennedy, A. Montgomery, J. W. Moore, W. Moore, C. Nixon, C. Norman, J. M. Redmond. Surgical Section (Council): Sir W. Stokes (President), W. Colles, C. Coppinger, H. Gray Croly, Kendal Franks, Edward Hamilton, P. J. Hayes, E. Stamer O'Grady, E. D. Mapother, W. Thornley Stoker, W. Ireland Wheeler. Obstetrical Section (Council): A. V. Macan (President), Lombe Atthill, J. A. Byrne, J. J. Cranny, Professor Dill, Andrew Horne, George H. Kidd, J. R. Kirkpatrick, T. M. Madden, R. D. Purefoy, William Roe. Pathological Section (Council): W. G. Smith (President), C. B. Ball, J. W. Beatty, E. H. Bennett, A. H. Benson, A. H. Corley, A. W. Foot, J. E. Little, J. M. Purser, J. A. Scott, J. B. Story. General Treasurer: George F. Duffey. General Secretary: William Thomson.

EARLSWOOD IDIOT ASYLUM.—The half-yearly meeting and autumnal election in connexion with this institution was held on the 29th ult. The asylum, which was founded in 1847 and incorporated by Royal Charter in 1868, shelters under its roof 566 inmates, of whom only 258 are able to engage in any industrial occupation. Of the latter, 201 are males and 57 females. The receipts during the past year amounted to £32,971 and the expenditure to about £26,862. The number of candidates for the thirty-five vacancies was 148.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARRETT, WILLIAM H., M.B., C.M.Edin., has been appointed Senior Demonstrator of Pathology in Edinburgh University, vice G. S. Woodhead, M.D., resigned.

BENJAFIELD, W. BARNETT, M.B., C.M.Ed., M.R.C.S., has been appointed Medical Officer for the Schools of the Strand Union.

COTTAM, F. H. W., M.R.C.S., has been appointed Resident Medical Officer to the Hospital for Consumption and Diseases of the Throat, Manchester, vice Alex. Milne, M.B., resigned.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.
All communications relating to the editorial business of the journal must be addressed "To the Editor."
Lectures, original articles, and reports should be written on one side only of the paper.
Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.
We cannot prescribe or recommend practitioners.
Local papers containing reports or news-paragraphs should be marked.
Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*
We cannot undertake to return MSS. not used.

DIRECT REPRESENTATION ON THE MEDICAL COUNCIL.

Dr. Joseph Rogers (who, we are glad to learn, is slowly recovering from the serious illness from which he has been suffering for many weeks) writes to explain that the omission of the name of Mr. Wheelhouse from his letter in our last issue arose purely from inadvertence.

Mr. W. H. Pepler.—A medical man is not required either by law or by etiquette to attend in reply to a message "sent by the police by a private messenger." If he has reason to believe that any person is in imminent danger of death, he is bound by the feelings of humanity to render his services. We advise our correspondent to demand in doubtful cases either a direct personal request from the police, or, failing that, an official printed form.

A Victim.—We do not see that any particular advantage would attend the publication of our correspondent's letter, the obvious moral of which is, *Caveat emptor*.

H. A. L.—Cassell's Household Medicine.

DAVID MANSON MEMORIAL HOSPITAL, FORMOSA.

To the Editor of THE LANCET.

SIR,—Permit me to offer a slight correction of your very kind and flattering allusion to the medical school of this hospital which was contained in THE LANCET of July 31st, p. 222.

You speak of a member of the Board of Examiners as "a native who is well educated in chemistry." It may save misunderstanding if I mention that the gentleman referred to is a distinguished graduate in medicine and surgery of Aberdeen and a member of the Royal College of Surgeons, England. Our object was to assemble as eminent and cosmopolitan a board as was possible to get together in this part of the world. How far we succeeded may be gathered from the following list of its members:—President: Deputy Surgeon-General Hungerford, P.M.O. Anatomy: Staff-Surgeon Preston, R.N.; Patrick Manson, M.D., LL.D. Surgery: Colonial Surgeon P. B. C. Ayres; C. Gerlach, M.D. (German). Chemistry and Physiology: Wm. Young, M.D., C.M.; Ho-Kai, M.B., C.M., M.R.C.S. (Chinese). Unfortunately, just at that moment there were no professional brethren of other nationalities within reach, or their assistance would have been solicited. The final examination will, in two years from the time of passing the first examination, be held in Shanghai, when I hope to obtain similarly generous aid from my brethren of all nationalities practising there, or who may be within hail. I am, Sir, yours faithfully,

W. WYKEHAM MYERS, M.B.

Hon. Surgeon and Instructor David Manson Memorial Hospital.

Takow, Formosa, Sept. 23rd, 1886.

THE UNUSUAL COINCIDENCE AT ST. THOMAS'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—The annotation in last week's LANCET giving an account of the simultaneous occurrence of pneumonia in husband and wife, induces me to send a brief outline account of a similar incidence of the disease which I met with last year in my practice. I consider that these coincidences are worth noting, as having probably a bearing upon one of the causes of pneumonia.

On April 11th, 1885, I was called to see a man, aged twenty-five years, suffering from acute inflammation of the apex of the left lung. The case ran the usual course to recovery, the only remarkable feature being the excessive amount of delirium, quite out of proportion to the area of lung involved. I may remark, in passing, that it has been a matter of observation with me that in cases of pneumonia attacking the apex there is more delirium than in those in which the base is primarily affected. I shall be glad to know if this coincides with the experience of others.

On April 14th, that is, three days after the commencement of the husband's illness, the wife, a strong young woman of thirty years of age, was attacked with acute inflammation of the right base. She was far advanced in pregnancy, and daily expected her second confinement. She progressed favourably for the next three days, but about 6 A.M., on the 18th, labour pains set in, and she was delivered in about two hours of a female child, which survived its birth only eighteen hours. There was no more than the usual quantity of hæmorrhage, but the extra call made by the expulsive efforts during the second stage of labour upon a respiratory system already heavily handicapped by a partially consolidated lung had a very exhausting effect. She never seemed to rally, gradually sinking until 4 P.M. of the 19th, when death took place.

In this instance as in the cases reported from St. Thomas's Hospital, the disease probably had a septic origin. The husband informed me that three days before he was taken ill they removed from a house in which they had lived for eighteen months because they never felt well in it, attributing this to bad smells emanating from the slop-stone pipe. The probability is that their insanitary surroundings had much to do with the simultaneous occurrence of pneumonia in these two young people.

I am, Sir, yours faithfully,

Farnworth, Nov. 1st, 1886. J. A. MACKENZIE, M.B. (Aberd.)

To the Editor of THE LANCET.

SIR,—It may be of interest to your readers for me to briefly record two cases, recently under my care, which possess some similarity to those quoted in your last impression under the heading "Unusual Coincidence."

At the end of last month I was called to see a man (G——) temporarily staying in our village on a visit with his wife. I found him to be suffering from pneumonia affecting his left base, and in addition I ascertained that he had gonorrhœa. My attention was then drawn to the wife, who was stated to have been unwell for some days, and found that she was affected with the same disorder (viz., gonorrhœa). Two days after my first visit the woman showed symptoms of some lung trouble, which on examination proved also to be pneumonia; but in her case the right base was affected. The disease ran a mild course in both (although in the man's case the symptoms were at first rather acute), and they were convalescent in little over a week.

Is one justified in thinking that the lung mischief had anything to do with the venereal complaint, and that this also was a case of pneumonia having a septic infection for its origin?

Knowing the many demands on your valuable space I have omitted all detail in my account.

Believe me, Sir, yours obediently,

Pontesbury, Salop, Nov. 1st, 1886. STUART OLIVER, L.S.A. Lond.

"DIPHTHERIA: ITS TREATMENT."

To the Editor of THE LANCET.

SIR,—If your correspondent, Mr. Merces, will refer to THE LANCET of April 10th last, he will see that in a long article I have advocated the employment of large, concentrated, and frequently repeated doses of the tincture of iron, and that, as I state there, for the last twenty years I have found it a most successful system of combating this terrible disease. I believe that iron has some specific action in arresting the rapid deterioration of the blood that takes place in diphtheria, and by its beneficent properties prevents the often disastrous lesions that are so fatal a concomitant of the disease. Since writing that article I have had communications from American physicians who had read it in THE LANCET, to the effect that it is not unusual in America to give even larger doses than I suggested, and speaking most highly of large and frequently repeated doses of the perchloride of iron in diphtheria.

I am, Sir, your obedient servant,

Sherborne, Oct. 31st, 1886. N. B. DAVIES.

"THE IRISH BRANCH COUNCIL AND THE APPROACHING ELECTION."

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 23rd Mr. Laffan of Cashel gives me credit undeservedly. It was Dr. Cox and Dr. C. Nixon who detected the flaw in the nomination paper.—I am, Sir, yours faithfully,

Dublin, Oct. 28th, 1886. J. P. DOYLE, Physician and Surgeon.

THE POPULATION OF FRANCE AND ITALY.

A. L. S. (Barrow-in-Furness).—A lively controversy has been going on in the journals of those two nationalities as to their respective populations, France maintaining that that of Italy is decimated by emigration; Italy hotly rebutting the statement and contending that of the two it is France that is showing signs of decrease. The outcome of the contest may thus be summarised:—Italy in 1871 had 26,801,154 inhabitants, and in 1881 she had 28,459,628—in other words, an increase of 1,658,474 within the decennium. Again, on Dec. 31st, 1885, by the excess of births over deaths, her population was computed at 29,699,785. In France, on the other hand, the increase of the population is distinctly less. At the end of 1876 her census showed 36,905,788 inhabitants, and at the end of 1885, 37,918,745—an increase of but 1,009,953, as compared with the preceding return. Again, France, on an average, has 102 births annually per 1000 women between the ages of fifteen and fifty, while in Italy the proportion is of 157 births. The emigration of Italians by no means neutralises this excess of births over deaths. From 1876 to 1885 about 449,000 emigrated to Transatlantic countries, of whom a considerable number after a year's absence came back. True, there has been an increase of emigrants in the years immediately preceding 1885, but still it is much lower than the numbers that annually leave Britain, Germany, and the Scandinavian countries. On an average, in the decennium 1876-85 there left Italy for non-European countries 158 per annum for every 100,000 of the population, while in the decennium 1875-84 the yearly emigrants from England were 440 per 100,000; from Scotland, 520; from Ireland, 1148; from Germany, 212; from Switzerland, 221; from Sweden, 423, and from Norway, 731. France, with her not inconsiderable colonies, not only cannot keep up a strong emigration, but has to reinforce by the foreign arm her national labour. Indeed, it is computed that she has a standing immigration yearly of between 40,000 and 50,000 workmen, mainly Germans and Italians, who become domiciled within her borders. In her last census (1885) over a million of such immigrants were calculated to have taken up their abode in her midst. The proportion of her births is very insignificant; insomuch that her political economists and hygienists are seriously preoccupied with the phenomenon, seeing in it a menace to the future prosperity and power of the country, as well as to her influence in competition with other States. For with existing means of defence and offence it is, above all things, numbers which tell in securing respect for a nation's integrity and independence.

Dental Student.—In some cases brandy would effect the desired object; in others it has been known to increase the difficulties of administration.

"CHRONIC DYSENTERY."

To the Editor of THE LANCET.

SIR,—In reply to "Eureka's" letter, in your last issue, asking for a suggestion as to the treatment of chronic dysentery, I would strongly urge him to try the following mode of treatment, which was recommended by Mr. Rawle, and is as follows:—1. Inject a pint and a half of warm water into the rectum at 90° F. 2. When this has come away, inject two ounces, by measure, with a gum-elastic bottle of the following: Quiniæ disulph., gr. x.; tinct. camph. co., ʒiv.; decoct. amyli ad ℥ij. It is generally retained; but if ejected, it may be repeated after an hour or two. I have tried this remedy in two cases of dysentery following military service in Egypt, and with most satisfactory results in both cases, after treatment by endless internal remedies. The injections may be given night and morning, and the effects are generally soon evident.

I am, Sir, your obedient servant,

ARTHUR G. BLOMFIELD.

Devon and Exeter Hospital, Nov. 1st, 1886.

To the Editor of THE LANCET.

SIR,—Last year I had charge of a case of chronic dysentery in a young man, in which the administration of fifteen minims of oil of turpentine in mucilage and cinnamon water twice a day, alternating with a three-grain pill of ipecacuanha powder twice a day—i.e., two doses of each daily,—produced a rapid improvement in the character of the stools and in the state of the patient. In a week the turpentine was discontinued, and a fortnight later one three-grain pill of ipecacuanha was sufficient to keep the stools in order. Subsequently, whenever he noticed any return of mucus or blood, the patient would take one pill daily. He contracted the disease in India, and was discharged from the army in consequence of his broken-down state of health. He had been given a variety of astringents, and was when I first saw him taking pills containing nitrate of silver and opium.

Trusting your correspondent, "Eureka," will be equally fortunate if he follow the treatment I did, I am, Sir, yours faithfully,

Oct. 30th, 1886, H. W. F.

To the Editor of THE LANCET.

SIR,—I would advise your correspondent, "Eureka," to give hamamelis virginica a fair trial in his case, and should be pleased if he would let me know the result. I am, yours faithfully,

St. Albans, Oct. 30th, 1886. A. H. BOYS.

DR. EDWIN MORRIS'S CANDIDATURE.

Dr. Edwin Morris has our hearty good wishes, and would make an excellent representative of general practitioners. The documents sent us for publication are too lengthy, and of the nature of advertisements.

A Hospital Dispenser.—Hospital dispensers must place themselves in the same category as chemists' assistants, only they have advantages which the latter do not possess. They are not required in most hospitals to produce certificates beyond those of good moral conduct, knowledge of drugs, and skill in dispensing. They have fixed hours. In some hospitals they take it in turn to remain until a late hour in case their services should be required. As a rule, they are better paid in proportion to their work. No one in authority would prefer a very young man, unless he possessed very good qualifications, to a senior. The question of pension depends upon the duration of service and the skill or devotion to duty shown by the particular dispenser. Those engaged in work the payment of which is dependent so often upon the charity of the benevolent cannot compare their position with that of those engaged in the public services.

Mr. R. S. Coulthard, M.B.—Mr. Eassie's book on Cremation of the Dead (*8s. 6d.*), and the Transactions of the Cremation Society, edited by the same gentleman (both works published by Smith, Elder, and Co.), would probably afford the information desired.

A. K. C.—Yes, under the circumstances detailed it would have been wise to have induced labour prematurely.

ABSCESS OF THE LIVER IN INDIA.

To the Editor of THE LANCET.

SIR,—With reference to Surgeon A. Tomes's remark in your issue of the 9th inst., to the effect that "abscess has never yet been met with in any person, native or European, below fifteen" in India, will you allow me to point out that I published in the *Indian Medical Gazette* for February, 1881, the particulars of a case—that of an infant of six months, whose liver contained not one, but seven different abscesses of this kind. The body of this infant was brought in for "the doctor's inspection," as it is called out there, by the police, as belonging to a proclaimed village or family in the district, and the examination was conducted by that enthusiastic pathologist and intelligent practitioner Dr. Wilkie, of the Bengal Army, who was at that time in medical charge of the Allahabad gaol. Excuse my availing myself of this opportunity to intimate here my extreme surprise at the strange and, to me, utterly inexplicable oblivion into which this my contribution to the literature or clinical history of this condition appears to have fallen. Though several books or essays have since been published on hepatitis in India, only one of them—viz., that of my friend, Dr. Chevers—has condescended to notice it; yet it not only cost me sixteen years of rigorous study on the spot, but it still, as I presume to think, "holds the field" as one of the most elaborate or exhaustive of its kind in our language. But then I have no handle before my name or string of honorary distinctions after it; I am neither a professor *en retraite*, nor yet a Knight of the Shire; I am not even of the quorum; and so it is as well, perhaps, as it is wise to ignore me.

I am Sir, your obedient servant,

Cedars Club, West Kensington, W., Oct. 12th, 1886. WM. CURRAN.

E.—As our correspondent puts the case he is quite in the right. An employer may justly claim to be satisfied as to the nature of the illness of one of his *employés*, and it is not unreasonable that he should wish to have the opinion of his own adviser; but a medical man requested to visit the patient of another medical man should communicate with the practitioner in attendance, and only see him in consultation or with the full assent of the gentleman in charge. That Dr. R—— should have declined a direct reply surprises us.

Edipus's communication arrived too late for consideration this week.

"HEREDITY IN LOWER ANIMALS."

To the Editor of THE LANCET.

SIR,—As I was abroad when my letter on the above subject appeared and did not return for some weeks subsequently, I do not know whether Mr. Weddell's interesting communication on the same subject is the only one that has followed mine. I had a kind note from Dr. Brown-Séquard enclosing a paper of his, and commending the publication of such facts bearing upon the very important question of heredity. All this encourages me to send you a story vouched for by a patient of mine, of a cat which had been taught to beg sitting up. Her kittens did not beg, but her kittens' kittens did so quite naturally, sitting up like the mother.

I am, Sir, your obediently,

Nov. 1st, 1886. GEORGE A. HAWKINS-AMBLER.

"TREATMENT OF OZÆNA."

To the Editor of THE LANCET.

SIR,—If "Subscriber" will try a solution of chloride of zinc, two grains to the ounce, and cause it to be injected warm with a glass syringe four or five times daily, I think much success will be obtained in this troublesome complaint.—I am, Sir, yours faithfully,

Brighton, Nov. 1st, 1886. C. H. WELCH, F.R.C.S.

THE BRITISH MEDICAL ASSOCIATION AND THE ELECTION.

A South Walian resents what he calls the dictatorial message in which some of the gentlemen connected with the British Medical Association offer their advice in favour of distinguished officials of that body as candidates for the direct representation of the profession in the Medical Council. In support of his complaint he sends two notes. One of his kind advisers does not mention anything about a third candidate. Of the other he says: "With regard to a third representative, he is good enough to allow me to indulge in my own fancy. 'But,' he adds, 'do not fail to vote for Foster and Wheelhouse.'" We must not venture to criticise the tactics of the zealous members of the Association. Our correspondent is not bound to accept the dictation. We publish a list of candidates from which to choose. Besides, the obvious friendship of one of his advisers is shown by his closing remark: "As I am off to Egypt, I can only wish you a merry Christmas and a happy new year when they come!" Can anything be more calculated to make a man vote right than such sentiments as these?

Ignoramus.—Our correspondent's questions seem rather unpractical. The power to charge for certain professional services depends on the nature of the qualification. The M.D. is not a surgical qualification. Our correspondent is not bound, we presume, to have all his qualifications registered, and may have any he pleases erased. The sanitary certificates are registrable only on special conditions. The registration of the M.B. and of the C.M. should take place at the same time; they are not given separately.

Conservative.—The sale of surgery fittings and fixtures, drugs, and bottles in conjunction with the transfer of a medical practice would, we believe, comprise and include dispensing counters, shelves, drawers, drugs, bottles, window blinds, and gas fittings, oil cloth or carpet, but not chairs, tables, &c.

LIFE ASSURANCE AND MEDICAL FEES.

To the Editor of THE LANCET.

SIR,—The practice of some life assurance companies tendering the paltry fee of half a guinea for examinations under such and such sums is absurd. I would ask, What has a medical man to do with the amount insured? The forms contain as many questions, the same number of organs are to be carefully examined, and the knowledge and skill required, as far as I can see, of the medical man are the same whether the sum be for £50 or £5000. I only regret that medical men are to be found who will do the work, and exercise the skill for the paltry sum. Why do not the insurance companies insist on their clients availing themselves of a qualified man (if possible their last attendant), make them pay for examination, and refund by small portions by reducing premiums or the insurance office find the money and augment the premiums until the guinea was refunded to them; or let the insurance office find one-half the fee, and their client the other half under such and such sums?

I am, Sir, yours truly,

Daventry, Oct. 27th, 1886. CUTHBERT JOHNSON.

A Constant Subscriber should apply at the office of the St. John Ambulance Association, St. John's-gate, Clerkenwell, for a copy of instructions.

Dr. Bernard O'Connor's letter is too long for insertion.

"REFUSE DISPOSAL."

To the Editor of THE LANCET.

SIR,—Under the above heading, in the current number of THE LANCET, I notice the following sentence:—"Whitechapel, we understand, has determined to depend upon cremation." Will you allow me to state that at the present time all the refuse from the houses in the Whitechapel district is being thus disposed of. I may mention briefly that, under the direction of Mr. La Rivière, surveyor to the Board, works have been constructed, and are actually in operation, which resolve unsavoury, and even dangerous, materials into inoffensive vapour and harmless useful clinker. Whitechapel is, I believe, at present the only metropolitan sanitary authority which so satisfactorily disposes of such refuse.

I am, Sir, yours faithfully,

JOSEPH LOANE,
Whitechapel, Oct. 29th, 1886. Medical Officer of Health.

THE LATE DR. MOXON.

To the Editor of THE LANCET.

SIR,—Soon after the death of the late Dr. Moxon an announcement of an intention to promote a suitable memorial appeared in the journals. As yet no public effort appears to have been made to carry this intention into effect. There must be many who, like myself, are anxious to subscribe their guinea to record their appreciation of the striking individuality and talent of the deceased physician, whose scrupulous, unselfish professional bearing, and generous, ever-ready sympathy must have endeared him to hundreds of his fellow practitioners. May I inquire through the medium of your columns whether any steps are being taken in the matter?

I am, Sir, yours faithfully,

Southport, Nov. 2nd, 1886. ROBERT HARRIS.

USE OF COCAINE IN MIDWIFERY PRACTICE.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 16th Mr. G. Pearce Baldwin writes to ask "the strength of the cocaine solution" used by me in obstetric practice. If he will turn again to the number of THE LANCET dated June 12th, he will see that I have stated that the compound I have found so useful is one containing cocaine six, vaseline seventy-four, and glycerine twenty parts. The statement "vaseline twenty-four" is a misprint, corrected in a subsequent number. I have lately been using a stronger preparation, and hope before long to publish notes of twenty cases of ordinary labour in which cocaine was applied. I regret having been prevented making an earlier reply to Mr. Baldwin's query.

I am, Sir, yours faithfully,

Chiswick, W., Nov. 3rd, 1886. BERNARD F. HARTZHORNE.

THE New York correspondent of the *Journal of the American Medical Association* writes:—"It has been reported that some of the physicians in the lower part of the city have of late been induced, either from a sense of pity, for a money consideration, or the sake of currying favour, to make out false certificates of death in the case of individuals dying of phthisis who were insured in cheap life insurance companies, which reserve the right to pay only half the amount of the policy to the beneficiary in the event of the person insured dying of consumption. It is to be hoped, for the honour of the profession, that the number of such medical men is exceedingly small; though that the thing actually occurs sometimes seems evident from the fact that a reputable physician, who reported to the Bureau of Vital Statistics the fact that he was asked by an undertaker to make out such a false death-certificate, is said to have remarked to a reporter who called to see him in reference to the circumstance: 'I can't afford to talk about this matter unless the newspapers are willing to pay me to move out of this neighbourhood.'"

Mr. John Jones (Brynddu).—1. The penalty is attached to the offence of falsely pretending to be, or take or use any name or title implying legal qualification.—2. The Apothecaries' Society has the power of prosecuting in the case mentioned.

FETID URINE.

To the Editor of THE LANCET.

SIR,—While salicylic and benzoic acids are both well-known remedial agents in ammonuria (*vide* Medical Digest, Appendix, 1028: 5 and 1067: 5), still nothing surpasses boracic acid, given in frequent ten-grain doses. Since Perez recommended this drug in THE LANCET (July, 1884, p. 133) I have very frequently used it, and have never been disappointed.

I am, Sir, yours truly,

Boundary-road, N.W., Nov. 1st, 1886. RICHARD NEALE, M.D. Lond.

Dr. Kucher (New York) will find a notice of his book in our issue of the 23rd ult.

An Old-standing L.K.Q.C.P.I.—The question is not one to be settled by the Medical Council.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Prosser James, London; Dr. B. W. Richardson, London; Mr. H. Power, London; Dr. Fothergill, London; Mr. Martin, London; Mr. John Holm, London; Dr. Donkin, London; Dr. Bantock, London; Dr. Marshall, Nottingham; Prof. Clay, Birmingham; Mr. Spurgin, Maryport; Mr. J. W. Joy, Paignton; Dr. H. W. Jones, Ilford; Mr. S. Oliver, Pontesbury; Dr. Rogers, London; Mr. Welch, Brighton; Mr. A. H. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Lectures ON DISEASES OF THE LACRYMAL APPARATUS.

Delivered at the Royal College of Surgeons.

BY HENRY POWER, F.R.C.S.

LECTURE III.—PART II.

ACCOUNTS of the post-mortem appearances presented by cases of lacrymal obstruction followed by lacrymal abscess and lacrymal fistula are singularly rare. I have never had an opportunity of making one myself, and I here reproduce a description of one made upwards of a hundred years ago by that excellent surgeon, Jean Janin, and recorded in his "Mémoire sur les Voies lacrymales" (p. 114, 1772):—Janin was requested in August, 1767, to see a woman, aged fifty-seven, in the Hôtel Dieu of Lyons, who had suffered for some years from lacrymal fistula of the right eye. The tumour of the sac was considerable, and the amount of matter which regurgitated through the puncta was so large that the eyelids, which were healthy, were covered with it. A few days afterwards the patient died from pleurisy. Advantage was taken of the opportunity to investigate the cause of the obstruction. M. Duffieu sawed through the head and carried the half to his rooms. Janin dissected with him the great angle of the eye with the object of displaying the canaliculi, which they had taken the precaution to tie with a silk thread near the puncta; the tumour of the lacrymal sac; and lastly, the bony nasal duct. Janin removed the anterior wall of the groove in the maxillary bone. As soon as the lacrymal passages were visible, it was observed that the upper part of the tumour rose more than a line and a quarter above the superior part of the groove in the os unguis; that the part of the nasal duct at which the tumour ended was constricted; that the rest of the canal was atrophied or withered as far as its orifice; and that the diameters of the canaliculi and that of the common duct were larger than natural. "We now," Janin says, "detached the lacrymal sac and the nasal duct from the os unguis. They were united by a multitude of bloodvessels and lymphatics; the os unguis was perfectly healthy. The lacrymal sac having been cut transversely about three lines from the point of constriction, a yellowish fluid exuded. The tunics of the sac were thinner than natural. After having washed the summit of the sac, we noticed that the internal walls had coalesced without any trace of ulceration, and that the openings of the pores were larger than natural. The section of the lower part being inverted, we found that the circumference of the constriction was plaited like the wristband of a shirt. A probe-pointed sound having been passed into the orifice of the nasal duct, I conducted it as far as the constriction without meeting any obstacle. The thickness of the constriction appeared to be about the third of a line. The canal being laid open as far as the sphincter or constricted part, it was noticed that the same folds or plaits were visible in the lower as in the upper segment. The resistance offered by the sphincter to the passage of a sound induced us to open it laterally lest it should be destroyed, and lest the folds that we had observed should be destroyed by compression. By this means it was shown that the walls at the seat of the stricture presented a rigidity and density which they did not elsewhere present. The canaliculi, being opened, presented nothing remarkable." He then describes the effects of boiling them in water for three hours. He also found some small tubercles in the upper part of the lacrymal sac, which he considered to be enlarged glands, and then advances a theory that the acrid secretion from these glands irritates the sphincter in the nasal duct and causes a mucocele, and finally irritates the sphincter at the puncta lacrymalia, after which an abscess-like swelling, though it does not contain real pus, which discharges itself by the cheek, and so on, into details in regard to which we need not follow him.

Auzias-Turenne[1] had the opportunity of dissecting the two lacrymal sacs of a woman who suffered from double dacryocystitis, and the account is exceedingly instructive. On the left side there was a swelling, and the least pressure upon it made a thin fluid of a purulent character regurgitate. On opening the sac, it was found to contain much pus and mucus mingled together; the mucous membrane was inflamed and the inner surface was lined with muco-purulent secretion. The corresponding canaliculi were patent, but the inferior orifice of the duct was closed by the swollen mucous membrane, which formed a plug. On the right side there was no swelling, though on opening it proved to be as much distended as the left. The membrane presented the same lesions. Notwithstanding this, the nasal canal was free, and had not undergone any material alteration. On this side, however, the canaliculi were closed. From this Auzias-Turenne concludes that an inflammation of the lacrymal passages was here the primary factor of the disease, and had led on the one hand to occlusion of the nasal duct, and on the other to closure of the canaliculi.

Malgaigne[2] records the case of a man, who died at the age of twenty-seven, who had suffered from double fistula from the age of twelve. Both osseous canals were so constricted that an ordinary stylet could not be introduced, but the mucous canals were not obliterated. Lencir gives a precisely similar case. Dubois records the case of a man who must have suffered much from surgery, since he ran the gauntlet of the Parisian surgeons for thirty years, none of whom were able to perforate the constriction even when sharp stylets were used.

There is the widest possible difference of opinion in regard to the presence of disease of the bones in lacrymal abscess. Janin,[3] for example, states that in his experience it is so rare for the os ungnis to be carious without some external cause or injury, that he doubts if it ever becomes so. Amongst the many cases he treated and his attention was particularly directed to this subject—he only met with one instance, and this was caused by a gunshot. Hence he thinks the plan adopted by the ancients of the application of the actual cautery as cruel as its indication is false, for it proceeds on the idea of the denudation and caries of the os unguis and adjoining bones. If it is ever successful, it is only owing to its stimulant action on the soft parts, the previously healthy bone being in all probability damaged by it. And so the subsequent use of a trocar or trephine is required to perforate the os unguis, not so much to establish a new route for the tears, as to destroy the bone supposed to be affected with caries. Janin even thought that ulceration of the sac was very rare. Now, on the other hand, Hasner[4] and Fano,[5] recent writers, believe that tumour and fistula of the lacrymal sac are the direct consequences of ostitis, and the latter proposes that the treatment should be applied to the bone affection. In regard to the frequency with which carious bone occurs in these cases, I find that in 124 cases in St. Bartholomew's Hospital, 36 men and 88 women, there were 14 cases in which bare bone was felt. Nine of these occurred in men, though I am of opinion that now and again the contact of the probe or sound with bone was due to a false passage being made. In some of these cases, as might be expected, the slitting up of the canaliculus, and the passage of a probe or the retention of a style, proved of little service, and the patient left the hospital with epiphora; but in such a case as the following it is probable I felt the bone as the result of a perforation of the wall of the sac: "Woman, aged eighteen. Obstruction for two years. Canaliculus slit up. Returned with epiphora after three months. Canaliculus again slit up; duct opened with probe; bare bone along whole course. Great improvement took place whilst the patient remained in hospital. After leaving the hospital for a month, she returned to show herself; the lacrymal trouble was then found entirely cured." I think we may fairly say here that the dead bone—which must, if the note be correct, have been of considerable extent—had not become detached; and we can hardly suppose it to have been either absorbed, or, if present, to have ceased to be troublesome. Zehender,[6] a

very good authority, believes that fistula consequent upon caries is a somewhat rare disease.

The importance of determining the length, calibre, and direction of the nasal duct is so great, in view of the frequency with which the operation is performed of slitting up the canaliculus, and the introduction of probes, sometimes of large size, into the duct, that I thought it would be interesting to examine a considerable number of the skulls in the Museum of the College (see Tables), and I desire to express my obligation to Mr. Gustavus Hartridge, assistant-surgeon at the Royal Westminster Ophthalmic Hospital, for the very great trouble he took, and the time he devoted, to the examination with me. The plan we adopted was in the first place to determine the length of the complete bony canal formed by the os unguis lacrymal bone and the complete bony canal together. We further thought it might be useful to measure the width from the inner margin of one groove to the inner margin of the opposite groove. Careful measurements were then taken of the width of the bony canal; and, lastly, two thick straight probes of wax were introduced for some distance down the ducts and kept applied to the grooves above, and their inclination noted. We examined in this way about 500 skulls, including Europeans, Asiatics, Negroes, Australians, Chinese, and others.

I shall endeavour to place before you some of the results we have obtained, and at the outset let me remark that measurements of this kind can only be approximate. To take the very first set of measurements—those that give the distance from the floor of the orbit through the nasal bony

and superior maxillary bone. This was done with a wax cylinder, which was introduced into the upper opening of the nasal duct, and pushed down till it touched the floor of the nose. A pin was stuck into it above at the level of the floor of the orbit. The length of the segment thus marked off gave the length of the complete bony canal and the space between its lower orifice and the floor of the nose. The cylinder was then drawn up till the lower extremity was only just visible through the nares, a point which was found on frequent examination to be immediately below the ridge for articulation with the inferior turbinal bone on the ascending or nasal process of the superior maxillary bone. This gave the length of the complete bony canal of the nasal duct. A third measurement was made, which gave the width of groove in the canal to the floor of the nose,—nothing would apparently seem easier, but, in point of fact, in a large number of cases it cannot be exactly taken. It is, indeed, easy to fix the superior limit—namely, the level of the floor of the orbit; but when a probe, or, as we used, a portion of wax taper, is passed down the canal, it is sometimes found to slope far backwards, so that it does not touch the floor of the nose till the posterior margin of the hard palate is almost reached, whilst in other instances the outer wall of the nasal fossa is so curved that it is difficult to determine the level of the floor. In the same manner, it is not easy to give the length of the lacrymal groove, since it becomes gradually shallower above till it is altogether lost. Still, as all the measurements were taken by the same hands, tolerable uniformity may be considered to have been arrived at.

First, then, in regard to the distance between the floor of the orbit and the floor of the nose, in millimetres, it was on the average:—

	mm.		mm.
In 292 Europeans	37·47	In 12 Peruvians	26·6
,, 114 Negroes	36·1	,, 22 Chinese	25·5
,, 23 Cingalese	36·47	,, 16 Polynesians	26·2
,, 27 Madras	22·22	,, 15 Andaman Islanders ...	22·4
,, 6 Vancouver's Islanders	26·0		

Secondly, in regard to the length of the complete bony canal formed by the os unguis and the superior maxillary bone, it was on the average:—

	mm.		mm.
In 287 Europeans	15·3	In 12 Peruvians	16·6
,, 114 Negroes	14·1	,, 22 Chinese	15·1
,, 23 Cingalese	15·0	,, 16 Polynesians	14·5
,, 27 Madras	13·7	,, 15 Andaman Islanders ...	13·0
,, 6 Vancouver's Islanders	15·0		

Next, in regard to the length of the groove and the complete bony canal, it was on the average:—

	mm.		mm.
In 286 Europeans	30·7	In 21 Chinese	30·7
,, 114 Negroes	29·0	,, 15 Polynesians	30·2
,, 23 Cingalese	30·2	,, 15 Andaman Islanders ...	27·4
,, 27 Madras	29·0	,, O'Beirne	43·0
,, 6 Vancouver's Islanders	31·0	,, Another giant	39·0
,, 12 Peruvians	32·32		

The average width between the vertical crests of the two lacrymal bones was:—

	mm.		mm.
In 290 Europeans	19·7	In 22 Chinese	19·2
,, 114 Negroes	21·0	,, 15 Andaman Islanders ...	19·8
,, 23 Cingalese	18·47	,, 17 Polynesians	17·3
,, 27 Madras	17·4	,, O'Beirne	28·0
,, 6 Vancouver's Islanders	19·0	,, Another giant	22·0
,, 12 Peruvians	18·5		

The transverse measurement varies within considerable limits—thus: skulls Nos. 3 and 329 are both 33 mm., whilst 81, 83, 129, and 137 are 17 mm., and 92 only 13 mm.

Address

ON THE

VALUE OF EXPLORATORY OPERATIONS IN THE PRACTICE OF SURGERY.

Delivered at the Inaugural Meeting of the Midland Medical Society, Birmingham, on Nov. 3rd, 1886,

BY THOMAS BRYANT, F.R.C.S.,

SENIOR SURGEON TO GUY'S HOSPITAL.

GENTLEMEN,—Your invitation to give the inaugural address of this the thirty-second session of the Midland Medical Society is an honour which I highly appreciate, and for which allow me at once to thank you warmly. In the execution of my task I trust I may be fortunate enough to bring before you some material for thought, sufficient either in quantity or quality to justify your choice, although in presence of the distinguished and critical audience I see before me I may well doubt my power of so doing. To excite your interest I have therefore selected a subject for my address which, if of no novelty in this assembly, is of importance both to the physician and surgeon, and which I believe will well repay an hour's consideration. My subject is the Value of Exploratory Operations in the Practice of Surgery.

As an occasional measure, an exploratory operation was not unknown to surgeons in the student days of my oldest hearer, but I am not sure that it was not almost entirely confined to such cases of strangulated hernia as had been pressed out of the hernial sac, out of sight, though not into the abdominal cavity; to such cases as were known as examples of reduction *en masse* or *en bloc*; to cases, indeed, then but little understood, but which have since been unravelled by the industry of my former colleague, Mr. John Birkett.[1] With the full knowledge and recognition of what is now known as displaced hernia, which Mr. Birkett's paper supplied, the value of the exploratory operation for diagnostic leading on to curative purposes became apparent, and it may be said with truth that the true importance of exploratory operative measures, as a principle of practice, then for the first time became so recognised as to be systematically adopted in our hospitals and taught in our schools. I must not forget, however, that an occasional exploratory operation was performed upon a diseased joint, when by the course of events its progress had been unsatisfactory and the question of its excision came to be entertained. In my *young* student days—now more years ago than I care to name—my late teacher, Charles Aston Key, performed several of these operations and resected shoulder- and elbow-joints after an exploratory incision, made with diagnostic intentions, had cleared up the nature of the case. The way in which he changed his line of action, and quietly decided, after inspection of the joint, on excision, amputation, or giving the joint a chance of a natural cure, is to me now, in my *advanced* student days, a very vivid and pleasant recollection. In recent periods exploratory operations have been more frequently undertaken, and they have been applied to a great variety of cases. This development of exploratory surgery is doubtless due to two main causes: firstly, to the increased confidence surgeons display in the primary treatment of wounds, which naturally springs from their full appreciation of the value of cleanliness in its highest and fullest sense, and from the use of antiseptics as aids to cleanliness; and, secondly, to the manner in which an exploratory operation can be conducted with a patient under the influence of an anæsthetic. In the pre-anæsthetic period exploratory operations were for the most part impracticable, as were most abdominal, prolonged, and delicate operations in which care and nicety of manipulation were essential to success. The surgeon's object was then to complete an operation, and to get rid of a local trouble as quickly as skill could carry out its object. Operations undertaken before spectators with watch in hand were not likely to be of an exploratory nature. In the present day, with anæsthetics at our command, all these things are changed. A surgeon with a patient anæsthetised can explore a part leisurely for diagnostic as well as for operative purposes. He can satisfy himself before he proceeds to complete his work that the disease for which he is about to operate is no other than the one diagnosed. Having decided that the measure contemplated is right, he can then proceed with his operation in all confidence. The operation itself he can also complete with every care and attention, since the necessity of speed in its execution has been practically eliminated; but he should at the same time remember—or, rather, not forget—that, as prolonged operations are detrimental to the patients, it is his duty to complete them as speedily as he can consistently with thoroughness; and that, moreover, as dilatoriness in execution is injurious to the art of surgery, he should not allow himself to lapse into slow and tedious ways, but accomplish with smartness and decision what he may have to do. I am convinced that these points have failed to secure sufficient attention, and that, as a consequence, many patients under the prolonged influence of the carbolic or other spray, and an indecisive manipulation, have suffered seriously. The art of operative surgery, besides, is likely from the same cause to degenerate into a fumbling process, which will neither redound to the credit of our profession nor the benefit of our patients. In saying this, however, I have no wish to see surgeons return to the hazardous, if brilliant, dash of the pre-anæsthetic period.

Exploratory operations are of value for *diagnostic* as well as *curative* purposes; and I take it, if we regard the operation from a clinical point of view, in order to justify the measure, these two purposes should as a rule be combined. To cut into any part of the human body merely with the view of learning something more than we previously knew of the nature of the disease we have to treat can hardly be considered a right proceeding, although if by that exploratory measure we have made one step forward in the treatment of the case, the nature of which prior to the exploratory incision was too obscure to justify operative action, the exploratory procedure must be pronounced justifiable. To cut into a tumour for diagnostic purposes which, whatever its nature, cannot be extirpated, would be a measure to be condemned; whilst to cut into a growth the nature of which can only be read with certainty after an incision has been made down to or [illegible] which, if of a

[1] Vide paper published in 1859 in the Transactions of the Royal Medical and Chirurgical Society.

cancerous kind, cannot be too early removed, is a scientific, conservative, and sound proceeding. Whether the swelling or tumour to be explored be in one of the extremities or in a superficial gland, as the breast, or whether it be situated in the lumbar region, beneath the abdominal muscles, or in the abdominal or pelvic cavities, does not affect the rightness or wrongness of the practice we are discussing, which must be pronounced wrong if it cannot lead to a sound treatment, but is right if it leads thither.

To illustrate this practice more fully let me apply it to regional surgery, and first of all to the breast and the treatment of its tumours. Let me ask the surgeons present how many breasts would each have saved and not removed, had an exploratory incision into the substance of the tumour been made for diagnostic purposes before the operation of excision had been proceeded with? By such a simple measure how many chronic abscesses of the breast would have been cured, and tumours composed of single serous cysts successfully treated, and the breasts saved? Could I canvass the surgeons present and confidentially from their private note-books obtain their statistics, I am convinced at least a score of these cases would be accumulated. I should head the list with one of cyst. By the adoption of an exploratory incision these cases would be saved. May fewer such errors occur to be recorded in the future! Again, let me ask how many lives would probably have been saved, with the mere sacrifice of a breast, if, in the first stage of lobular cancerous infiltration of the breast gland, the true nature of the disease had been clearly revealed by a well-timed exploratory incision, followed, on the diagnosis of the case being thus made manifest, by an excision of the affected organ? Might not surgeons fairly expect, by the general adoption of this exploratory incision into such breasts, better results as to a long immunity from disease, and probably a larger number of cures than can now be recorded, when valuable time is too often lost whilst the case is being watched to make the diagnosis sure, and at the same time the disease from having been purely local, is spreading by local if not by lymphatic or vascular infection? I have in dealing with breast tumours during the last few years acted on this principle, and have not regretted it. I have saved breasts the seat of cystic trouble which would otherwise have been excised, and in cases that have turned out to have been carcinoma I have been led to remove them early, when the epitheliomatous elements were confined to the breast structure itself, and the disease, clinically, could be pronounced to be local. Such treatment as this must surely lead up to better results than can now be recorded. By it it is to be hoped that with the lapse of time a cure of the local cancerous affection may become a reality, in the same way as surgeons now record cases of undoubted cure after the removal of a local epithelial disease from other structures, such as the lip and skin generally.

In disease of the testicle it is hardly necessary to point out the wisdom of a like practice. In such affections an exploratory incision, before excision is proceeded with, can never do harm. By the adoption of the practice, as a rule, testicles lost in hæmatoceles will be always saved and never removed, as occasionally now they are, under a wrong diagnosis. In the following interesting case I have reason to hope the same practice has been successful; time must, however, be the prover. The case as it stands is in my knowledge unique, and consequently claims record.

Encysted Hæmatocele of the Testis, the Cyst being situated beneath the Tunica Albuginea; incision; cure. (Dresser, Mr. A. J. Taylor; Ward-clerk, Mr. J. D. Cruickshank).—George C——, aged twenty-three, a labourer, living at Sandringham, Norfolk, was admitted into Guy's Hospital, under the care of Mr. Bryant, on May 21st, and discharged on June 26th, 1886. Six years previously, the patient noticed that the left testicle was swelling. There was no pain in it. Five years ago the swelling was tapped, and about three ounces of clear fluid were drawn off. The scrotum was thereby reduced to its normal size, and did not again swell for about three or four years. During the last year the swelling had increased, and was tapped eleven days before admission, when only a small quantity of fluid escaped, and with it was mixed a little blood. There was scarcely any decrease in the size of the testicle after this tapping. The patient then came to Guy's Hospital. He had had no injury or gonorrhœa. On admission, he was a fairly well nourished man, rather pale; and said he felt quite well in himself. The left side of the [illegible] ...vied by a swelling which [illegible] ...r from above downwards, and two inches and a half from side to side. The testicle on the other side measured two inches from above downwards, and one inch from side to side. The swelling was quite painless, and made up of three smaller swellings. The one below was firm, and felt like the body of the testicle, though the patient did not experience any special testicular sensation when pressure was made on this swelling. The second, above, felt tense and elastic. A third swelling, on the outside of the two others, felt hard and solid, and measured one inch from above downwards, and three-quarters of an inch from side to side. The skin of the scrotum was discoloured, being of a purplish-blue colour. The glands in both groins could be felt, but were not enlarged. The patient said the testicle was not painful or tender; it only inconvenienced him by causing a sensation of weight. The chest was resonant; the breath sounds and heart sounds were normal. Temperature 97·6° F.; pulse 68; respiration 22. The urine was clear; sp. gr. 1026; it contained no albumen or sugar, but a slight precipitate, which cleared up with nitric acid, and under the microscope was seen to be amorphous phosphate. On May 24th Mr. Bryant saw the patient and considered the case to be one for exploration. On the 28th, chloroform having been administered, the tumour was held in the left hand and the skin made tense over it. An incision, an inch and a quarter long, was made in the middle line of the tumour, and the structures were divided down to the tunica vaginalis, the cavity of which was found to be completely obliterated by adhesions. The tunica albuginea, being exposed, appeared to be tense and distended as if by fluid or growth. A puncture was made in the cyst wall beneath the tunica albuginea, and a small quantity of blood spurted out. The opening was enlarged to the size of the skin incision, all its fluid contents (measuring about an ounce and a half) were turned out, and the cavity was examined. It was found to be a cyst with a perfectly smooth lining, the wall being composed of thickened tissue. The testicle was felt to be normal, lying in a position somewhat behind and below the cavity. The cyst wall was covered by the tunica albuginea. The cavity was washed out with iodine water, and packed with strips of iodoform gauze so as to promote suppuration. There was no hæmorrhage beyond a little capillary oozing. The operation lasted a quarter of an hour. The cyst appeared to occupy the position of the corpus Morgagni, and it was thought that there had been a hydrocele developed in connexion with this body which had been converted into a hæmatocele by the previous tappings. Microscopically, nothing but blood-cells could be seen in the fluid which was in the cyst. The patient was sick after the chloroform.—May 31st: The external dressings had been changed each morning, but the plug was not removed from the cavity until this morning. Nor could this be done until chloroform was given, as the edges of the cavity had nearly closed. When a finger was afterwards introduced into the cyst cavity, it was found to be lined with healthy granulations. The wound looked healthy, and the discharge from it was slight and consisted of blood-stained serum, there being no pus. Oiled dressing was passed into the wound. From this date until June 11th the patient progressed favourably. The wound was dressed daily with iodoform gauze, and a small drainage-tube was kept in position. There was no pain in the wound except when it was dressed. The edges of the wound became covered with healthy pink granulations. On June 6th the drainage-tube was left out. On the 11th the wound measured two inches from above downwards, by one inch across. The patient complained of pain whilst passing urine; but there was no urethritis. On the 12th the tonsils were enlarged and red, and the patient began to be feverish; but the scrotal wound remained healthy. On the 13th the evening temperature was as high as 103·2°. On the 14th the evening temperature had fallen to 99·2°, and the throat felt easier, though it did not look any better. On the 16th the patient had diarrhœa, and much difficulty in talking or swallowing. On the 17th, as both tonsils were greatly enlarged, red, and tense, Mr. Bryant made a small incision into each, but no pus came away. The patient had had no shivering, and his temperature in the morning before the operation was 99° F.; the diarrhœa still continued. On the 18th, the left tonsil was smaller, but the patient did not feel that he was relieved by the previous day's operation. Gargles and poultices to the throat had been used for a week past; now it was ordered that the throat be painted with glycerine and tannic acid. On the 19th, the house-surgeon

removed both tonsils with the guillotine; no suppuration was found in either tonsil. On the 21st, the wound, which was still dressed every other day, measured an inch and a half by half an inch, and was quite superficial. The granulations, being prominent, were touched with nitrate of silver. The throat was much better, and the patient could talk and swallow with ease. He, however, could not sleep; consequently an injection of morphia (a quarter of a grain) was given hypodermically at night. On the 26th the patient went home. The scrotal wound was a superficial granulating surface, which measured one inch by a quarter of an inch. The testicle could be moved about quite freely and without pain; it was not at all adherent to the granulating surface. As measured between the fingers, both testicles appeared of the same size. The throat was still swollen, but not painful. When seen some months later he was well.

In diseases of joints it would be well if the operation of excision were, as a rule of practice, preceded by an exploratory incision. The clear knowledge of the true condition of the affected joint gained by the proceeding would doubtless induce the surgeon in many cases to adopt a less heroic treatment than excision, and trust more to the reparative power of nature, after a free vent to disorganised tissues had been afforded by the incision, or, possibly, necrosed bone had been taken away. I could exemplify this practice fully by cases had I time; but my object to-day is to illustrate a principle. The exploratory measure would likewise prevent the possibility of comparatively healthy joints being resected under an erroneous diagnosis.

In abdominal, renal, vesical, and pelvic surgery, the value of exploratory operations for diagnostic leading up to curative purposes is, however, the best shown; and it is here that the greatest care is requisite, in order that a measure which is so good when rightly regulated should not be abused or misused. Let me put a case. A surgeon is called to see a patient with every symptom of acute strangulation of the intestine. He searches diligently for some external hernia, and fails to find one. What is he to do? Is he, before adopting any decided line of treatment, to stand by and watch the progress of the case with the hope, on the Micawber principle, of something turning up, either to relieve the patient (a very remote possibility), or to indicate the exact cause of strangulation? Or should he, for diagnostic purposes, at once perform an exploratory abdominal incision, the incision itself in all probability enabling him to discover the cause of the symptoms or strangulation; divide a band, if present; relieve an internal hernia; possibly undo a volvulus; or press out an intussusception? I have no hesitation in stating that his line of duty lies in the way of action, and not of inaction, since success is probable under the active practice advocated, and most improbable, if not impossible, under the expectant inaction. Where the symptoms are associated with an external hernia, displaced by manipulation or otherwise, every sound surgeon would sanction immediate exploration; why should the same line of action be wrong under circumstances which are so slightly dissimilar? To stand still for a correct diognosis to be made as to the exact cause of strangulation is, as a rule, to wait for a post-mortem examination. It should be enough, with a certain combination of symptoms present, for the surgeon to know that strangulation exists, and, for this, action is called for. With such a diagnosis, when the cause is *certain*, as an external hernia, the line of treatment is definite; it is in every text-book. When the diagnosis as to the exact cause of strangulation is *uncertain*, although problematical, the diagnosis should be made more certain, or cleared up by an exploratory operation, more particularly where the exploratory incision will in all probability be the direct means of hopeful surgical treatment. In a case of acute intestinal strangulation or of obstruction, as it is too commonly wrongly called, to be asked to wait to see the effect of medicines, with the hope that kind nature will find some means of relief, is, to the surgeon who mentally sees a probable strangulation from a band, twist, or internal hernia, a wicked weakness: seeing that by medical treatment one case recovers, and, it may be added, to the astonishment of all; whilst eleven die, to the astonishment of none. Is it right, may I ask, that eleven cases should be allowed to drift, when the chances against success from purely medical and expectant treatment are so small? Ought not cases of intestinal strangulation and obstruction to be regarded more from the surgical point of view than the medical? And should not the question of mechanical relief be the point for *primary*, and that of medical relief for *secondary* consideration? Ought not the question of exploratory operation for diagnostic purposes to stand in the very foreground of every such case? I maintain that this question of operation should be the very first to be considered in every case of what has been called acute obstruction, but which, I hold, should be regarded as one of acute strangulation. If this question be answered affirmatively, let action promptly follow decision. If negatively, let medicine and expectancy have fair play. But, under all circumstances, let the diagnosis and line of treatment based upon it correspond.

Again, should an acute peritonitis be present, and its cause be obscure—should some deep-seated abdominal or pelvic suppuration exist, and its true position be only guessed at, is it a wiser and safer practice to treat the patient on the expectant principle, and let the trouble take its course, which, as a rule, lies in a downward direction, or is it more reasonable, hopeful, and surgical to learn through an exploratory abdominal incision something more of the case's origin, and thus treat it? If the cause be some cæcal perforation (the most probable) the exploratory operation will not only give diagnostic information, but be the direct means of giving relief. If it be suppuration connected with a pelvic organ, the same result will be obtained; and if the cause of inflammation and suppuration be obscure, by the exploratory incision a vent to the inflammatory or purulent fluids will be afforded, and thus a better chance than existed before be given to the patient. For suppuration in the peritoneal cavity, ovary, or Fallopian tube should be dealt with as elsewhere by evacuation, irrigation, and drainage. By this line of treatment I am convinced a better result will in the future be recorded than the present method can show.

Acting upon this principle, I, in 1867, opened the abdomen of a gentleman aged fifty-one, and divided a band, and the patient was alive eighteen years subsequently.[2] In 1884 I opened the abdomen of a young man, aged twenty-two, who had had symptoms of strangulated bowel for six days. I found a band at once near the prominence of the sacrum, and divided it without the slightest trouble. All active symptoms at once ceased, and the bowels acted freely. He died, however, on the sixth day from perforation; the operation had been too long deferred. I have performed the same operation on three other occasions at least, but with no life-saving success. The band was readily found in all, and divided, but the patients were too depressed to rally. These results are not to discourage us. If life was not saved in all the cases it was because the bowel was too damaged before operative relief was given, and success under these circumstances is no more to be expected than it can be in cases of external hernia which have been allowed to drift. The lesson to be learnt from these failures is the necessity of promptitude.

I must here, however, give you two cases, which have never been recorded, in which life was saved by an exploratory operation under most unpromising circumstances. In both cases deep-seated abdominal suppuration existed. In one the course of events clearly showed it was connected with the cæcum or its appendix. In the other case I can only say the suppuration existed behind the mesentery, but its cause has never been made clear. Both cases well illustrate the value of an exploratory operation.

The first case alluded to I saw on October 17th, 1885, with Dr. Hubbard, of Elgin-road, Notting-hill. The patient was a healthy girl, aged twelve, the eldest of a family of five. In November, 1884—that is, eleven months before I was consulted,—the child was suddenly taken ill with high fever (temperature 102° F.), a furred tongue, and intense pain in the right iliac fossa. She was treated by Dr. Hubbard, and recovered sufficiently to get up and run about; but similar attacks recurred at uncertain intervals during the next nine months. Early in October, 1885, another attack occurred, associated with pain and tenderness more in the right lumbar than the iliac region. Some swelling was likewise visible. When I saw her on Oct. 17th the child was very ill, with feverish symptoms. The right thigh was somewhat flexed upon the pelvis, and extension caused pain. The abdomen was hard from muscular rigidity, and anything like pressure over the right iliac or lumbar regions caused pain. There was clearly some fulness in these parts. I felt sure some deep-seated suppuration existed. Under

these circumstances, I next day gave some anæsthetic, and cut down through the abdominal muscles above and behind the crest of the right ilium, and evacuated two or three ounces of fetid pus; with the pus passed a puff of wind. The pus flowed from above the wound as well as from below, and, as I believed the abscess to have some connexion with the cæcum, I enlarged the opening downwards in front of the anterior superior iliac spine, washed out the cavity well with iodine water until it returned as clear as it entered, and put in a drainage-tube. After this the acute symptoms subsided and fever disappeared, but the abscess did not heal. For two months it continued to discharge a little, although the abscess cavity was well irrigated. On two occasions the tube was taken out, but, retained secretion giving trouble, it was reintroduced. About the end of the second month I saw the child again, and when probing the wound I thought I felt a hard body. This suspicion was proved to have been correct, for on Jan. 26th, 1886, a hardened orange pip passed from the sinus [specimen handed round], and in three weeks the child was convalescent. She is now perfectly well. Whether this pip had become impacted in and subsequently ulcerated through the cæcal appendix, or whether it had passed more directly through an ulcer in the cæcum, may be an open point; but the case is given here as a good example of the value of an exploratory incision through the abdominal walls, and possibly into the peritoneal cavity.

The second case was one of peritonitis following retro-peritoneal suppuration in a child about five years of age. The true cause of the abscess was obscure; it may have been due to accident. It evidently had no connexion with any intestinal or abdominal viscus. The case could not have recovered if it had been left alone. The exploratory operation alone saved life. I give the report somewhat condensed from the notes of Mr. Samuel Mills, who called in my assistance, and ably and skilfully conducted the case after the operation to its final successful ending.

Archibald P——, aged four years and eleven months, a fair boy of delicate appearance, was the patient. Mr. Mills was called to him on July 15th, 1885, and was told by the boy's mother that he had been screaming with pain in his abdomen during the night. He had on the previous day had shivering and some vomiting of water and mucus, due, as the mother considered, to his having eaten some ripe gooseberries the same morning. He had fallen down a staircase, a distance of eight or ten feet, a few days previously to the illness. He complained of having hurt his back and stomach after he fell, but he seemed all right next day. He was in great pain, when seen by Mr. Mills, across the lower part of the abdomen and around the umbilicus, at which points he was also very tender, the slightest pressure increasing the pain. The recti muscles were rigid and contracted. There was slight general swelling of the abdomen, and, as far as could be made out, slight dulness below the umbilicus in the centre. There was tympanitic resonance at the epigastrium, and in both flanks. The bowels had been relieved twice during the night and morning, the result of a white powder administered the night before. The temperature was 103°, pulse 140. The cheeks were flushed; the pain was more or less continuous, but with occasional exacerbation, causing him to scream loudly. The tongue was thickly coated with grey fur. Mr. Mills ordered hot turpentine stupes to be applied to the abdomen, a mixture of acetate of ammonia, aconite, and four-drop doses of laudanum every three hours, with iced milk and soda-water to drink. His mother stated that he had been very ill whilst visiting at Ventnor ten weeks previously, in a similar manner, and had been under the care of Dr. Harvey, of that town. The illness had lasted upwards of three weeks, and the boy had subsequently been home seven weeks, but had not thoroughly recovered his looks and former strength. On July 16th the patient was no better; he had scarcely slept; the abdomen was slightly more swollen and tender. There had been no further action of the bowels or vomiting. Temperature 103·8°; pulse 145. Mr. Mills ordered the entire abdomen to be smeared with equal parts of extract of belladonna and glycerine. The dose of laudanum was increased to five drops every three hours. On the 17th the patient's state was about the same. The evening temperature was 104°, and the pulse 150. An enema of thin gruel with turpentine and castor oil came away, slightly tinged only with fæcal matter from the lower part of the rectum. On the 18th the patient seemed [illegible] draught of morphia (one-third of [illegible] night had produced no relief. The abdomen was more swollen, and was tympanitic except in the centre line below the umbilicus. The dulness extended down to the pubes and to each iliac region; but there was resonance in the flanks. As the boy had not passed much urine, a catheter was used, and two ounces of urine were drawn off. The rectum, examined digitally, was found to be quite empty; whilst nothing abnormal could be felt. There had been no action of the bowels, no rigors, and no vomiting; but the abdominal pain was much the same. On the 19th the boy passed another bad night; his abdomen was more swollen; and he looked pinched in the face. Mr. Mills advised a consultation with Mr. Bryant, as he thought the only chance for the boy lay in making an abdominal section, with the hope of releasing some purulent collection, probably in connexion with the cæcum. Mr. Bryant saw the boy, and decided to make a section on the right side of the abdomen. Mr. C. Coward administered chloroform. The urine, of which there were two ounces, was drawn off through a catheter. Mr. Bryant first made an incision about the right semilunar line, and opened the abdominal cavity. Distended and slightly injected intestine appeared at the wound, and from it some clear serum escaped. On the introduction of a finger through the wound towards the median line of the body, its passage was arrested by some central swelling which pressed forwards from the spine, and as it was thought this swelling could be better dealt with from the left side of the abdomen, it was decided to close the wound already made. The abdominal cavity was well sponged and the wound stitched, care being observed in suturing the peritoneum. The left side of the abdomen was then opened in the same way, and an abscess cavity that contained two or three ounces of thick pus, and which was situated behind the mesentery, was opened, evacuated, irrigated, and drained. A large drainage-tube was left in the otherwise closed wound. The peritoneum was thoroughly cleaned. The boy was under continuous chloroform anæsthesia for an hour and three-quarters. During the operations all instruments, sponges, and hands were immersed in a 2 per cent. solution of carbolic acid. Carbolic oil dressings, and carbolised gauze with absorbent cotton-wool paddings and flannel bandage, were applied. Three hours after the operation the patient had had a little vomiting, possibly due to the chloroform, and complained of pain in the abdomen. A third of a grain of morphia in two drachms of water was given by the mouth and retained. Five hours later he had slept, and was more comfortable. On July 20th it was noted that he had passed a better night than any previously since the beginning of his illness. The bowels acted twice spontaneously; on the second occasion the motion was rather relaxed, but contained neither blood nor mucus. The bandage and dressings were soiled with rather offensive-smelling discharge. Dark greenish-yellow discharge was escaping through the drainage-tube, which was kept clean by the injection of a warm carbolised stream of water through it into the cavity of the abscess, by which the cavity was also thoroughly cleansed. Fresh dressings, similar to the former, were again applied. The boy took milk and beef-tea readily. His temperature was 102·2°; pulse 130. The morphia (one-third of a grain) was repeated. On the 21st the bowels had acted four times; the motions were loose, but otherwise natural. On the 22nd the wounds were dressed. All silk sutures had cut their way through the edges of the wound, which was widely gaping and suppurating. A regular granulating tract was established from the abscess by the left wound. The cavity of the abscess was syringed out, and the tube with the rest of the dressings was replaced. On the 23rd the note was that the bowels had acted three or four times daily; a bismuth and opium mixture was therefore given. On the 24th the boy had a good deal of pain in the abdomen; there was very little discharge from the tube, which did not reach to the bottom of the wound. Pressure on the right side of the abdomen brought to the surface some accumulated pus. The left wound was dressed night and morning. The note on Aug. 1st was to the effect that the boy had gone on very much the same during the past week. The right wound was granulating, the left one discharging freely. He had pain in the right loin, which was fuller in appearance than the left side. He complained also if pressed over the right loin. He was placed on his left hip and side for a few hours each day, so as to assist the escape of pus from the left wound and the tube. He took some solid food with about three ounces of brandy during twenty-four hours. The bowels

continued relaxed in spite of the constant administration of bismuth and opium mixture. He was remarkably tolerant of opium. On the 8th the wound was granulating; the granulations looked pale and flabby. Thin watery pus escaped through the tube. He was extremely thin and emaciated, taking semi-solid food with beef-tea and brandy, and quinine (half a grain) every four hours. On the 15th the tube was removed. On the 22nd the patient was sitting up, partially dressed; the right wound was nearly healed, the left wound still discharging a little. He subsequently quite convalesced, and on Nov. 20th was said to be well. In August of this present year he still remained quite well.

I must not allow myself to enter into the question of making exploratory abdominal incisions when any suspicion exists of serious or suppurative troubles about the uterine appendages; and happily my so doing is not needed, since you have in one of your members an advocate of the practice of extreme power and of unquestionable success who would certainly go as far as, and probably further than, I can go in favour of exploratory measures in these classes of cases. Mr. Lawson Tait's experience, skill in operating, and success encourage him to do what men of less power and experience had better not attempt; and I would say to him, "Go on, and prosper." To a surgeon who can show "139 consecutive cases in two years of ovarian and parovarian cystomata removed without a death, and 113 exploratory abdominal section cases with only three deaths—these three, moreover, dying from the disease, and not the operation,"[a] I, as a general surgeon, can only bow in all modesty, and envy the specialist who can publish such figures. I may, however, say this: When a woman has an abdominal or pelvic disease which in all human probability, if left alone, will destroy her life, and there is a fair reason to suspect that that disease is curable by operative measures, I hold that an exploratory incision by which a definite diagnosis can be made is not only a justifiable but a called-for measure, more particularly when the exploratory incision can be employed as a step in the operation by which the woman may be cured. If by the exploratory incision a negative conclusion is obtained—the negative conclusion being, in fact, positive knowledge—and the curative operation cannot be completed, the patient has incurred a risk—possibly, some would say, a trivial risk—but no more. But, however great or trivial the risk may be, if it has been fully explained beforehand to the patient, or to her or his friends, and has been accepted, the surgeon's responsibility, whatever the results, is but slight. Let the surgeon see, however, in all these cases, that the patient is made acquainted with, and a party to, this proceeding. To submit an adult patient at any time to an operation without making him or her clearly understand the risks and effects, immediate and remote, of the operation is an error—I should say a very grave error. It is one that cannot be supported by argument. No one here would like to be so treated.

It is true that exploratory operations must at times be expected to fail, and abdominal operations in particular, since abdominal cases are always complex, and their diagnosis difficult and sometimes uncertain. This very difficulty, however, in a manner supports the argument in favour of exploratory measures, for by such, and such alone, can a sound diagnosis often be made. I may say most truly that, of the exploratory abdominal operations I have made, I have never regretted having made one. Where success has not followed the exploration, it has *not* been from the incision, but for want of its early application. A strangulated bowel from a band may be released "too late," as may a strangulated bowel in a hernia. It cannot be expected to recover under the one circumstance more than under the other. Experience tells us also that at times, when an abdomen has been opened under the hope that some band or internal hernia may be present, nothing but a peritonitis with its effusions has been found, and it must be added that in some cases after the exploratory operation convalescence followed. I have had the pleasure of seeing such a case as the subjoined in the hands of my colleagues, Dr. F. Taylor and Mr. C. Symonds, and I know of others.

Acute Peritonitis simulating Intestinal Obstruction; abdominal exploration; recovery.—John W——, aged twenty-three, on April 26th, 1886, in the early part of the day, felt pain in the abdomen, which increased and became very severe at 10 P.M. Vomiting ensued, which lasted through the night. During the next two days he vomited and had pain. On April 29th Dr. Fredk. Taylor saw him, when the vomit was green and abundant. The patient looked ill, with sunken face; and his abdomen was full and tympanitic, but without local tenderness, and without visible coils of intestine. The bowels had not acted since the onset of the illness, nor had any flatus passed per rectum. The case being of a very doubtful nature, it was decided on the 30th to explore the abdominal cavity. This was done by a median incision, and acute peritonitis affecting mainly the lower abdominal zone and the pelvic peritoneum was found. There was no distension of the bowel. Coils of small intestine occupied the pelvis. The region of the cæcum was healthy and the appendix was free. A urinous odour was detected once on a sponge used in the pelvis, but as there was no pus and no fluid it was decided to close the wound. The recovery was interrupted once by the formation of a deep swelling on the right side, probably peritoneal in origin. This subsided.

It transpired that this patient had suffered from stricture of the urethra and cystitis, had had threatenings of a prostatic abscess, and had once before had a somewhat similar though milder attack. In all probability the peritonitis was secondary to some prostatic or vesical trouble. How far the exploratory incision acted towards the recovery it is difficult to say, since it is of course known that cases of peritonitis, from whatever cause, occasionally recover under medical treatment. This fact, indeed, is a treacherous one, since it helps to foster a dilatory if hopeful line of practice, and prevents the medical mind seeking early surgical assistance. What a story a surgeon of any long experince could tell of the evils of procrastination. "Too late! too late!" in his hands would be a text for a series of instructive, though sad, lectures. What a story a physician of experience could tell of recoveries without the surgeon's aid, when such aid was contemplated; and from the latter the evils of too early interference might be inferred. In both conclusions much truth is embodied. I do not, however, hesitate to assert that much more harm has in abdominal intestinal surgery followed the expectant than the operative treatment; and that, if the latter has not been as successful as it ought to have been, it is because it has not had a fair chance. Too late interference has been the rule, promptitude the exception; and let us remember that in these cases the operative interference must in its object be exploratory.

(To be concluded.)

[a] Tait: Edin. Med. Journal, May, 1886.

ON THE TREATMENT OF SNEEZING, HAY FEVER, ASTHMA, ETC., BY THE GALVANO-CAUTERY.

BY F. DE HAVILLAND HALL, M.D.

ALL introducers of novel medical or surgical procedures are apt to run to extreme lengths and to arrogate to the plans they have brought forward claims to which they can have no pretension; hence the caution with which the statements of innovators must be received. It would be a great pity, however, if these extravagant assertions should prevent attention being paid to the kernel of truth contained in the husk of excessive laudation, and this seems especially needful in regard to the views propounded by Hack of Freiburg, who undertook to cure a large number of neurotic affections by the free use of the galvano-cautery to the mucous membrane covering the inferior turbinated bone; later on, he certainly modified his opinion somewhat, but he still claims too large a field for this plan of treatment. That there are certain neurotic affections the starting-point of which is the nasal mucous membrane cannot, I think, be denied, and in these cases cure can be most readily effected by treatment directed to the part primarily affected. Hack, by pointing out that the most ready method of influencing the nutrition of the mucous membrane of the nose is by the employment of the galvano-cautery, has enabled us to treat successfully and promptly many cases formerly very difficult to manage. As a type of the kind of case in which I would use the galvano-cautery to the nose the following may be taken as a good example.

Mrs. C——, aged two[illegible] was sent to me last May by my friend Dr. [illegible] following account

of herself. She said that she had been married eighteen months. In June, 1885, while pregnant, she commenced to suffer from violent fits of sneezing; these continued to occur very frequently until Oct. 25th, when she was delivered of a stillborn child, the limbs of which were said to be much contorted. On inquiry, I found that for the last three or four years she had suffered from hay fever, usually lasting about a month. When she applied to me in May, she stated that she was again pregnant, being rather more than three months advanced; that the fits of sneezing had recurred as severely as last year; and that her doctor had advised her that it was of the utmost importance, in view of what had occurred in her former pregnancy, that she should seek relief from her distressing ailment. Apart from the sneezing, her general health was excellent in every respect. I found the mucous membrane covering the inferior turbinated bone on the right side greatly hypertrophied; the same condition, though somewhat less marked, existed on the left side. After applying a solution of cocaine, I used the galvano-cautery (as described later on) to both nostrils. The patient did not complain of any pain from the procedure. She was directed to come again in a fortnight. As I was unfortunately prevented by illness from seeing her, Mr. Butlin kindly made the second application of the galvano-cautery. I next saw her on July 3rd. She informed me that the sneezing was not so bad as formerly; it was less frequent at night, and there were only about four attacks daily. On examining the nose, the mucous membrane was found to have contracted to such an extent that I did not think it necessary to make another application of the galvano-cautery. I recommended her to use a 2 per cent. solution of cocaine in the form of spray night and morning, and to have a bottle of carbolised smelling-salts to inhale whenever an attack of sneezing seemed imminent. The further history of the patient is best told in an extract from a letter I received from her husband on Aug. 17th: "I am very pleased to be able to report *very great* improvement; I cannot say that it has quite left her, but it is only very occasional now, and nothing like it used to be. The carbolised salts prevented many an attack of sneezing, and she is able to do without the spray, and I think it may now be said that she is cured of a most inconvenient and, in her case, dangerous complaint."

When I undertook the treatment of this case I was not very sanguine as to success. In the first place, I do not think that the condition of the nervous and vascular system which obtains in pregnancy is likely to influence favourably a procedure, the object of which is to remove the tendency towards certain reflex actions by diminishing or annihilating the irritability of the locality upon which the train of symptoms depends. Secondly, it was to my mind very uncertain to what extent the fœtus in utero was itself the predisposing cause of the attacks. In favour of this view was the fact that after delivery the attacks ceased, only to recommence when she became pregnant. Lastly, there was the history of several attacks of hay fever, and I was afraid that though she might get temporary relief, nevertheless during the summer months she would probably have a return of the complaint. The result, however, was better than I expected.

The introduction of cocaine has inaugurated a new era in the treatment of nasal diseases and of the various reflex symptoms dependent thereon. This has been brought about in two ways: firstly, and most important, the local anæsthetic effect of cocaine enables one to perform most operations within the nose without causing the patient pain worth speaking of, and without having recourse to general anæsthesia; and, secondly, by the power it has of causing contraction of the nasal mucous membrane, a much better view can be obtained of the posterior nares. The method of treatment I employ is the following. In the first place, it is necessary to make an examination of the nasal mucous membrane without the use of cocaine, otherwise, owing to the action of the drug to which I have just alluded, the hypertrophied parts might be overlooked. Having settled which areas are to be attacked, I spray out the nostril with a 10 per cent. solution of cocaine. Then I wait five minutes, and apply, by means of the brush, a 20 per cent. solution of the same drug to the part of the mucous membrane which is to be cauterised. Again waiting five minutes, I try if the sensibility of the mucous membrane is annihilated; if not, I wait a little longer, or, if necessary, make a second application with the brush. As soon as I have satisfied myself that the mucous membrane is insensible to pain, I make two or three deep incisions in the mucous membrane by means of one of Schech's delicate platinum-headed galvano-cautery instruments heated to a red heat by a galvanic battery. All that the patient will have to do after the operation is to pass a little cold cream or zinc ointment up the nose, which will relieve the smarting caused by the burning. In about a week or ten days, according to the depth of the furrows and the idiosyncrasy of the patient, the burns will have healed, and, if necessary, a further application may be made, though I prefer to wait two or three weeks to see how much contraction has taken place before repeating the process. If the cocaine has been properly applied, there is little or no pain at the time of the operation, and though occasionally the patients complain of the smarting which comes on the next day, some cooling application generally suffices to relieve this.

Notwithstanding that I have a firm belief in the efficacy of this operation—if so simple a procedure may be dignified by the name,—I do not usually employ it till I have tried other measures and failed. I remember one case in particular which I saw three years ago. In this patient there was hypertrophy of the mucous membrane of the nose, with the history of violent attacks of sneezing and running from the nose; after a time the sneezing ceased, and was replaced by attacks of asthma, coming on about 1 A.M. and lasting till 4. I had quite made up my mind to operate, but, as the patient was pregnant, I thought it advisable to wait until after her confinement, so I ordered her a mixture containing three grains of citrate of caffeine and ten grains of bromide of potassium. I did not see the patient again for some months, but on her next visit she told me that she had experienced great relief from the mixture, and that she had not had a bad attack of asthma since her last visit. I have seen her again within the last few months, but, as her condition has much improved, I do not think it will be necessary to have recourse to the galvano-cautery. In vol. i. of the Westminster Hospital Reports, I have recorded a case of excessive sneezing which had lasted for eleven months; in this patient, syringing out the nostrils with a lukewarm solution containing the glycerine of carbolic acid, borax, and the bicarbonate of soda, sufficed to effect a speedy cure. I have mentioned these two cases to show that it is not necessary in all attacks of violent and protracted sneezing, hay fever, asthma, &c., to employ the galvano-cautery, though in some cases the cautery is the most speedy and certain method of treatment.

Before ending this short account I would wish to direct attention to the carbolised smelling-salts, from which the patient on whose case this communication is based derived much benefit. I have ordered the salts very frequently, and they almost invariably give relief; and to persons prone to coryza I would strongly recommend them. Directly the usual indications of a cold in the head are experienced the salts should be inhaled, and recourse had to them every ten or fifteen minutes while the irritation about the nose lasts. In my own case I have aborted many a threatened attack of coryza by this means. As regards the use of cocaine spray for the relief of hay asthma, I do not think much good is to be expected from this drug; the constringing action which at first results from its use is followed by a dilatation of the vessels, and the fluxion which accompanies this sometimes sets free the reflex, which results in an attack of sneezing or asthma.

Wimpole-street, W.

ON THE

DIAGNOSIS OF UNILATERAL PYELITIS AND PYO-NEPHROSIS IN WOMEN.

BY ARTHUR LEWERS, M.D. LOND.,

ASSISTANT OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

IN women when the urine contains pus, and when for various reasons we suspect that the pus comes, in part at least, from the urinary tract above the bladder, it becomes a matter of importance to determine if possible whether the pus comes from one side or both sides, the possibility of relief by nephrectomy being kept in mind. To decide this point catheterisation of the ureters has been proposed and carried out by various observers; the practical difficulties of this proceeding are, however, so great that it is unlikely to come

into general use. On this point Skene says:[1] "Catheterisation of the ureters has been performed by Simon and Winckel, but as it is difficult, not without danger, and of little practical value, I shall not dwell upon it here." Again, Erichsen says:[2] "Catheterism of the ureter, even in the female, cannot be carried out with sufficient certainty to be of any use." The method to which I desire to call attention is, on the other hand, easy of execution, and in the case in which it was tried gave a perfectly satisfactory result. It is as follows: The urethra is dilated; then one piece of a Bryant's rectal speculum is passed along the urethra into the bladder, and so placed that, seen from the front, it occupies one lateral half of the urethra and bladder beyond. When in this position the speculum divides the bladder into two compartments; for example, supposing the speculum occupies the right lateral half of the urethra and bladder, then the orifice of the left ureter is in view. The surface is gently mopped with cotton-wool, and then the character of the urine escaping from the ureter is observed. As it collects in the hollow of the speculum, some of it may be taken up with a syringe and tested in the usual way. Having finished the examination of the left ureter, the speculum is now quickly turned round so as to lie in the left lateral half of the urethra, thus bringing the orifice of the right ureter into view. When this was done in the case about to be narrated, a little fountain of clear urine about a quarter of an inch high escaped from the right ureter, the exit of the urine from it having evidently been prevented by pressure of the speculum while the left ureter was being observed. Here also, if the obvious characters of the urine do not at once settle the point at issue, some may be collected and tested. The electric light is necessary for illumination, unless direct sunlight be available. In the following case observations made in the manner described showed that suppuration was taking place on one side only, as pus was seen steadily oozing from the left ureter and clear urine came from the right. Guided by the oozing of the pus from one particular point, a hollow probe was passed two inches along the left ureter, but I was not able to pass the probe along the right ureter. The evidence already obtained would not, however, have been rendered any more conclusive by catheterisation of the ureters. I think, then, that in women when the urine contains pus, and when, owing to other considerations—for instance, wasting, fever, failure to improve under local treatment, such as washing out the bladder with antiseptic lotions,—we have reason to believe that the presence of pus is not to be accounted for by cystitis alone, the method above described should be employed with a view to give the patient the benefit of surgical treatment if the affection prove to be unilateral. The following is an abstract of the case referred to:—

A. G——, aged eighteen, shop assistant, was admitted to the London Hospital on May 15th, 1886, complaining of inability to hold her urine. She first began to experience micturition trouble in November, 1885. She noticed then that she had to void urine more frequently than she had to do before, and had to get up at night to pass it. In January, 1886, she began to have some pain during micturition, which became more and more frequent, and at last the bladder was so irritable that for some time before she came to the hospital she had been quite unable to hold her urine. She had never passed blood with her urine. On one occasion, in April, 1886, the patient had a pain across the small of the back and in the stomach. The pain was severe and shooting; it came on suddenly and went away suddenly; it did not cause nausea or vomiting, nor did it pass down towards the legs.

On admission, the patient was anæmic, but fairly well nourished; the temperature normal. There was no tenderness in the abdomen, nor anything abnormal to be felt there. Vulva and skin adjacent to it red and sore-looking. Hymen perfect, but lax. On vaginal examination, pressure on the anterior vaginal wall caused pain, much more than the same pressure on the posterior vaginal wall. The uterus and its appendages were normal. The sound passed into bladder a distance of three inches or rather less, the measurement being taken from the external orifice of the urethra. The passage of the sound caused pain. About a drachm of urine was obtained by passing a catheter; reaction amphoteric; it contained pus in abundance, and some shreds or flakes; no casts; only pus-cells and bladder epithelium were seen under the microscope. The other organs were healthy.

The case was thought to be one of cystitis only for some time, and the bladder was washed out daily with liquor carbonis detergens (one drachm to a pint) and afterwards with boracic acid lotion, without however, any improvement taking place.—May 31st: The temperature had hitherto been normal; but from this date onwards the patient suffered from attacks of high fever running an irregular course; the temperature on several occasions being as high as 104°.—July 8th: Examined under ether to-day. No tumour to be felt in the region of either kidney.—Aug. 21st: The patient has lost 13 lb. in weight since June 14th.—31st: There have been general pains during the attacks of fever, but no pain specially referred to the region of the kidneys. For the last three weeks increased resistance has been felt in the region of the left kidney; palpation causing some pain, and exciting the abdominal muscles to contract. When the patient lay on her face, dulness over the left kidney in the back was found to reach two fingers' breadth lower than over the right kidney. Under ether a lump was easily felt in the situation of the left kidney. The observations on the character of the urine flowing from the right and left ureters respectively were then made, as described at the beginning of this paper. My colleague, Mr. Treves, saw the case with me, and it was agreed that it was probably one of scrofulous degeneration of the left kidney, and that the right kidney was healthy, as evidenced by the urine flowing from its ureter. Although the patient's condition was most unfavourable, yet, as the rapid loss of weight and other grave symptoms made it certain that the case must end fatally in a short time if left alone, we felt it right to suggest operative interference to the patient and her friends, at the same time putting the risk fairly before them. Consent having been readily given, Mr. Treves accordingly operated. The patient did very well after the operation and the temperature was persistently lower than it had been previously, though still febrile. The urine contained (three weeks after the operation) a small quantity of pus, due no doubt to the cystitis which still remained. The amount of pus in the urine was trifling, however, when compared to the large quantity passed before removal of the kidney.

Whatever the ultimate result may be in this particular case, there is no doubt that a diagnosis sufficiently probable to justify an exploratory operation could have been made by the method described months earlier when no tumour was to be felt in the abdomen, and before the patient's strength had been so much reduced as to render her a very unfavourable subject for operative interference at all.

Note on the Operation by Mr. Treves.—"The kidney was approached by the ordinary lumbar incision. It was embedded in an extensive mass of tough adhesions. It was subsequently found that this perinephritic inflammation was the main constituent of the 'renal' tumour, since the gland itself was but little enlarged. The adhesions were broken down with difficulty. It was found impossible to separate the kidney from its capsule or from the supra-renal body. The latter structure, with the entire kidney, were therefore removed. A surgical pedicle could not be established. The ureter, distended with caseous and purulent matter, gave way, the renal vessels were clamped and subsequently ligatured. The kidney was entirely occupied by a series of tubercular abscesses. The wound was stuffed with sponge covered with iodoform, and the cavity left to granulate up."

ON THE

THERAPEUTIC USES OF THE HOT BATH.

By W. J. NOTLEY, M.D.

THE application of heat in various ways to the surface of the body has long been recognised as a remedial agent of no small power, and the hot-air and vapour baths are often resorted to, either by the advice of the medical man or empirically, from a knowledge of the good results previously obtained from them. By those who have written on the subject, the effects of these baths are ascribed almost entirely to their action on the skin; and if any more remote influence is attributed to them, [illegible] through the skin as an organ of el[illegible] believed to be

brought about. The hot-water bath, on the other hand, is usually regarded with dread, and persons who are advised to take a warm bath are commonly enjoined with the greatest earnestness not to allow the attendant to have the water in the bath at a higher temperature than 98° or 100° F. It is no doubt a wise precaution to warn those who are the subjects of serious cardiac disease or of any profound circulatory derangement to guard against too hot a bath or too long a continuance in a bath of any kind whatever; and we caution such persons with equal earnestness against anything that may put a great or sudden strain upon the heart or arterial system. In such cases we prohibit football, and running to catch a train, an omnibus, or a tramcar; but it does not follow that people whose vascular systems are ordinarily sound may not indulge in these pleasures, if pleasures they are, to their heart's content; while to a great many of those whose muscles become weak and flabby from want of use, a good deal more running and jumping than they usually get would be beneficial in the highest degree. In the same way, it has appeared to me that persons suffering from various disorders, always excepting those above mentioned, may take the hot bath without danger, and in many cases with great advantage to themselves. By the hot bath I mean, in the case of the wet bath, one at a temperature ranging from 100° to 110° Fahrenheit. In the dry-air bath a temperature much higher than this can of course be borne.

Some time ago an opportunity was afforded me of making some observations on the effect of the hot bath in removing some morbid conditions of the system. A man of middle life, in temperament nervous-sanguine, spare, and somewhat below the average height and weight, complained of languor, debility, want of energy, and lowness of spirits. On examination it was found that his heart and arteries were sound, though his circulation was rather weak. His alimentary system was fairly good, though the quantity of food taken was below the average. His skin was somewhat dry, and a few spots of psoriasis were found on the extensor aspects of the legs, arms, and trunk. His urine was cloudy with phosphates, and below the average in quantity. As the Turkish bath was not in this case available, he was advised to take a water bath at a temperature of 105° F., and directions were given him how to proceed in case of faintness. The day after taking the bath his condition was wonderfully improved. His circulation was stronger, his urine was clear, and he now felt cheerful and well. This improved state of matters continued for about twelve days, when all the unpleasant symptoms reappeared, and he began to feel as ill and dejected as ever. The most natural proceeding was, of course, to order him another bath, and this he took with the same happy result as before. Since that time he has had the hot bath about once a fortnight, and by this means has managed to keep himself in very tolerable health and spirits.

It would be interesting to know the exact means by which the hot bath produces this powerful and beneficial effect on the system. It must, in the first place, be carefully borne in mind that the warm bath at a temperature below 100° F. has no influence that can be compared with the results to be obtained from the hot bath. The hot bath stimulates the whole system, and the effect of this stimulation appears to last for some time, for the patient above referred to remained well for about a fortnight after taking the bath. Having ascertained that his diet was as nearly uniform as possible, the quantity of urea excreted on three successive days immediately before and after the bath was estimated by Russell and West's method, with the following result:—

Average quantity of urine in twenty-four hours for three days *before* the bath ...	916·67 cc.
Average weight of urea in twenty-four hours for three days *before* the bath ...	22·8 grms.
Average quantity of urine in twenty-four hours for three days *after* the bath ...	1040 cc.
Average weight of urea in twenty-four hours for three days *after* the bath ...	26·25 grms.

From this it appears that the quantity of urine and the weight of urea excreted were below what are usually stated to be the averages for a healthy man, but that both were very perceptibly increased by the hot bath. If we may assume that the other excretions and excretions were proportionally [illegible] clear evidence as to the [illegible] brought about [illegible] Perhaps we may compare the action of the hot bath with the action of any other irritant of moderate severity. The theory of counter-irritation is confessedly somewhat hazy and inadequate; but it is a matter of every-day observation that a moderate stimulation of the skin relieves congestion of internal organs immediately subjacent to the area of stimulation. In many cases there is only a remote connexion between the vascular supply of the viscera so acted upon and the portion of skin stimulated. It must be by a reflex action of the nervous system that a poultice over the loins can relieve congestion of the kidneys, or one on the skin of the chest can benefit a similar condition in the lungs. It is not unreasonable to suppose that there is some sort of connexion between the centres presiding over the vascular supply of any portion of the body surface and those regulating similarly the quantity of blood proceeding to the organs lying immediately beneath. Thus a stimulus applied to any portion of the skin would lead to an increased activity of the nerve centre presiding over this area of the body surface, and so relieve any existing congestion of the connected or contiguous centre governing the vascular supply of the viscera lying in the neighbourhood of the stimulated surface. I think it was Dr. Berry Hart, of Edinburgh, who first suggested this explanation of the action of counter-irritants. In this way, then, the hot bath would relieve congestion of many centres, and by restoring them to a healthy action would promote the circulation of healthy blood not only through the thoracic and abdominal organs, but also through the higher nerve centres, thereby leading to the dispersion of those morbid feelings conjured up by the faulty nutrition of the cerebral convolutions. Whether this be really the mechanism by which the good effects described above are produced, or whether some other explanation can be given, it seems clear enough that the hot-water bath might be used, with proper precautions, in many cases difficult to treat in any other way, such as chronic gastric catarrh and the protean forms of dyspepsia. One of the most marked effects of the hot bath is seen in the increased force of the circulation, and following necessarily from this an increased degree of muscular energy, with a corresponding increase of activity in the mental functions. In short, the flagging energies are restored and a more healthy tone is given to the whole system.

As in most other remedies, so in the case of the hot bath, the time and manner of application are of some importance. Like all other baths, the hot bath should be taken before the principal meal of the day, and if this meal be taken early the good results will be more certain than if it be taken late. The duration of the bath should be about fifteen minutes, and the temperature should be about 105° F. If faintness should come on while in the bath, the whole head should be immersed in the hot water, and kept there for a few seconds, when the faintness will disappear. The usual directions given in public baths are to get out of the bath as soon as drowsiness or faintness begins and to ring for the attendant; but anyone who attempts to do this will most certainly aggravate his danger. As pointed out some time ago by Mr. Benham and subsequently by myself, the application of heat to the head is a potent means of averting syncope. From time to time we hear of deaths in the warm bath; and I am convinced that many of these might have been prevented by the adoption of the simple method referred to, instead of the deadly and often impossible means commonly recommended.

Birmingham.

PAROTITIS FOLLOWING OVARIOTOMY.

By W. H. JALLAND, F.R.C.S.,
SURGEON TO THE YORK COUNTY HOSPITAL.

DURING the month of January last there were some letters in THE LANCET upon the connexion between the parotid gland and the genital organs, more especially with reference to operations on the latter being followed by inflammation of the former. Mr. Stephen Paget, in his letter published on Jan. 9th, quotes five cases of parotitis following ovariotomy published by Professor Möricke, and one other case which occurred at St. Bartholomew's Hospital. As this seems a comparatively rare occurrence, I enclose the notes of the following case, which was under my care in the York County Hospital. The patient was admitted on Sept.

17th, 1885, and was not operated on until the 21st of the following month. During the whole of the time she was in the hospital no case of mumps occurred, nor, as far as we could gather, were there any mumps amongst the friends or in the family of any of the friends that came to visit her, so I think we may fairly assume that she did not contract this disease from an external source. The notes of the case were taken by Mr. E. F. Morris, house-surgeon.

Mary P——, aged twenty-one, servant, was admitted into the York County Hospital on Sept. 17th, 1885. She gives the following history. About three years ago she felt very weak—much more so than she had done for some years previously. She consulted a medical man, who treated her for weakness and pain in her left side of a sharp shooting nature, situated over the tenth and eleventh ribs. This continued for a year without any other signs or symptoms, when she noticed that her body was enlarged (then about half its present size); it had slowly increased. The only symptoms she now complained of were weakness, headache, and pain in her left side and legs. Bowels rather costive. She commenced to menstruate at the age of fourteen; this continued normally for three or four months, then stopped again for more than a year. Since then she has been very irregular, sometimes going for two or three months, sometimes only a fortnight.

On examination, the chest &c. appeared normal, but a distinct trace of albumen was found in the urine. Nothing else was noticed except an abnormal abdomen. The family history was good. She had been quite well up to fourteen years of age.

On examination of the abdomen, it was found to be distinctly enlarged, and, as it were, by two bodies: one, more or less round, filling up the right pelvis and reaching to the umbilicus; another, seemingly more oblong, passing up into the left flank. On palpation the swelling was more or less felt. Both bodies were regular, and in no way nodular. No other bodies could be felt; no wave, fluctuation, or thrill could be obtained. On percussion, there was dulness over the centre of the tumour extending immediately down to the pubes; resonance in both flanks, but much more marked in the right, the left being comparatively dull. The umbilicus in no way protruded. Per vaginam, the uterus was normal in position and length; os virginal; distinct movement in front of the uterus on movement of the abdominal swelling; otherwise the parts were normal. Measurement above umbilicus, 32½ in.; below, 36 in.

Oct. 21st: To-day, under ether, Mr. Jalland performed ovariotomy. Abdominal wall very adipose, but hæmorrhage very slight. On opening the peritoneum the tumour was found to be cystic and non-adherent. It was tapped and some fluid drawn off, when it was seen to be polycystic. With some little difficulty the growth was lifted out of the abdomen and removed. The pedicle, which was not a very broad one, was tied in two pieces with Chinese silk. The other ovary was also found to be slightly cystic, and was likewise removed. The abdomen was then wiped out with sponges, as there was some ascitic fluid in the pelvis. The abdominal wall was then stitched up with wire and catgut, and the wound dressed antiseptically. The spray was used prior to, but not during, the operation.—21st: At 6.30 P.M. the patient had well recovered from the ether, the vomiting being very slight immediately after operation. Temperature 99°; pulse 108. Ice was given.—22nd: Patient easy and well. No pain. Temperature 98·6°; pulse 96. Diet of milk, lime, and ice, in teaspoonfuls. At 8.20 P.M. the temperature, was 100·8°.—23rd: At 10 A.M. there was some slight vomiting; otherwise well. Temperature 100·2°.—24th: This morning the patient complained of some stiffness of the neck, with pain at the angle of the right jaw. There is now slight swelling over the right parotid gland, which is very tender. In the evening the swelling and pain had increased.—25th: At 3 A.M. the patient was in very great pain; right side of face immensely swollen. Temperature 103°; poultices ordered. The patient had passed an uneasy night; slept but little; pain very severe; swelling increasing. Three leeches ordered. At 6 P.M. the patient was better, the swelling less, and the pain not so great. Temperature 101°.—26th: Swelling disappearing; pain less; feels better; no abdominal symptoms. Temperature 99·2°; pulse 105.—28th: Right side of face painless, but still swollen.—30th: Left side of face swollen and painful. Leeches ordered.—Nov. 2nd: Pain nearly all gone; both sides of face still somewhat swollen.—4th: Antiseptics left off; wound almost healed. The patient is now practically well.

A Mirror of HOSPITAL PRACTICE, BRITISH AND FOREIGN.

GUY'S HOSPITAL.

CASES OF STRANGULATED HERNIA; OPERATION FOR REDUCTION AND EXCISION OF THE SAC; REMARKS.

(Under the care of Mr. R. CLEMENT LUCAS.)

MR. CLEMENT LUCAS has long maintained that an operation for strangulated hernia ought not to be considered complete until the sac has been excised, and that the after-treatment is often unnecessarily prolonged. Formerly, it used to be considered always advisable to keep a patient lying in the hospital for a month or six weeks after kelotomy. After excising the sac, in uncomplicated cases, he completely closes the canal and the wound. Primary union is thus obtained, and the patient sits up on the sixth day, and leaves the hospital, wearing a truss, on the fourteenth day after the operation. In a paper read before the Clinical Society in October, 1885, Mr. Lucas showed how, by excising the sac and suturing the umbilical aperture, the mortality after the operation for umbilical hernia might be lessened. It will be observed in the following cases, two of which were femoral and one inguinal, complicated with undescended testicle, the patients in each case left the hospital well on the fourteenth day. It is hoped that others will more generally adopt this method of treating strangulated hernia. For the reports of the three cases, all operated upon within a week, we are indebted to Mr. Metzgar, the dresser, who attended to the patients after the operations.

CASE 1. *Strangulated Hernia in an Infant complicated with undescended Testicle; Operation for Reduction; Excision of Sac and Testicle.*—W. J. C——, aged one year and eleven months, was admitted into Lydia ward on the evening of Sept. 1st, at 11 P.M., suffering from strangulated inguinal hernia on the right side. A hernia had first come down in that position when he was three months old, his mother returning it by pressure. As the testicle had not descended on that side, a truss had not been applied, but his mother had been warned of the danger and instructed to come to the hospital immediately if the hernia became irreducible, or if at any time the testicle appeared, in order that on the descent of that organ a truss might be adjusted above it. At 3 o'clock that afternoon the child's bowels had been opened, and at 8 o'clock, whilst crying, the hernia came down, it being rather larger than it had ever been before—viz, the size of an ordinary hen's egg. His mother tried to return it as she generally did, but was unable; so he was brought to the hospital.

On admission the patient's temperature was 100·2° and the pulse 105. The hernia being very tense, an icebag was applied till 12 P.M., when he commenced to vomit for the first time. Taxis was then employed, but for a short time only, and, the hernia being unreduced, chloroform was administered. Mr. Lucas then tried taxis in the inverted position, but, owing to the tense condition of the tumour, for a short time only. An oblique incision was then made over the tumour, and the structures were severally divided down to the sac; as the hernia was not constricted externally to that structure, it was opened. Some turbid serum was let out, and it was seen that, though dull in colour, the intestines still maintained their characteristic shiny appearance. The constriction, which was at the internal ring, was then divided and the bowel returned. The testicle was found lying about three-quarters of an inch below the internal ring; the sac containing the testicle was then separated and, having been transfixed and tied with a double catgut ligature, was excised. The margins of the canal were then sewn up with [redacted] ligatures, these going deeply into [redacted] incision having

been sutured with wire, carbolic dressings were applied; strict antiseptic precautions having been observed during the operation. The patient was then put to bed, with a pillow under his knees, and pillows arranged supporting his back after the manner of an inclined plane. He was ordered one minim of tincture of opium every three hours, and one pint of milk in the next twenty-four hours.—2 A.M.: Asleep, no sickness.

Sept. 2nd.—The patient has slept well all night. No sickness. Temperature 101·4°; pulse 110. Opium omitted.

3rd.—Wound dressed; looking well. Temperature 99°; pulse 90.

4th.—Temperature 97·6°; pulse 88. Wound dressed; all wire sutures removed. Bowels opened; motions not formed. Taking three pints of milk.

6th.—Temperature 98·2°. Allowed three pints of milk and one of beef-tea.

7th.—Has been gradually improving for the last two days. Temperature 97·2°. Sat up in bed for two hours.

8th. Temperature 97·8°. As the bowels have not been opened for four days, a soap enema was administered, which acted freely. Had some boiled sole for dinner. Has sat up all day.

On the 10th a truss was fitted, and on the 14th the child went out quite well.

Remarks.—It will be noticed that in this case the congenital hernial sac was complicated by an undescended testis. In operating on the tumour in the inguinal canal Mr. Lucas first came upon the testicle, which was drawn on one side to allow the sac to be opened above it. The stricture was a very tight one at the internal ring, which appeared to be further external than normal. To prevent the recurrence of strangulation and to lessen the risks after the operation, Mr. Lucas sacrificed the undeveloped testis, ligaturing the cord and sac together at the internal abdominal ring and cutting everything away. The canal was afterwards drawn together by chromicised gut, cut short and left, and the skin wired up. No suppuration took place, and recovery was complete in a fortnight.

CASE 2. *Strangulated Femoral Hernia in a Female; Operation for Reduction; Excision of the Sac; Suture of the Canal.*—E. W——, aged forty-six years, was admitted into Lydia ward at 1 P.M. on September 2nd. She had suffered from a left femoral hernia for fifteen months, for which she had worn trusses, but, as all of them had fitted badly, the hernia frequently came down, being attended with vomiting. She could always reduce it herself. It came down at 12 o'clock on the previous evening, being rather larger than usual, and as she was unable to reduce it she came to the hospital; she had not vomited.

On admission the temperature was 100·8°. The hernia was very tense, being about the size of a pigeon's egg. Ice was applied at once, and was continued for an hour, when taxis was employed; but the hernia was still irreducible. Vomiting occurred soon after her admission. Mr. Lucas was sent for, and ether having been administered (the pulse being weak, 128), he attempted to reduce the hernia by taxis, but being unsuccessful a vertical incision was made over the tumour; the tissues were then divided down to the sac, which was found to be not constricted at the saphenous opening, so it was opened, when some serum escaped, and the bowel was seen to be of a dark purplish colour. The constriction, which was at Gimbernat's ligature, was then divided, and the bowel returned; the sac was separated, transfixed, double-ligatured with catgut, and excised; the canal was afterwards sewn up with chromic catgut, and the skin incision was closed with wire sutures. The patient was then propped up in bed, as in the former case. She was sick once immediately after the operation. Ordered one-grain pill of opium every six hours, and a pint of milk and two ounces of brandy in the twenty-four hours.

Sept. 3rd.—Slept well. Temperature 99·4°; pulse 86. Some retention of urine was relieved by the catheter.

4th.—Going on well. Wound dressed; looks well. The opium pill to be given night and morning only. Temperature 98·2°. Passed flatus.

5th.—Wound dressed, wire sutures removed.

6th.—Enema of warm water administered, but was ineffectual. Diet: two pints of milk, one egg, and a pint of beef-tea.

7th. Bowels opened as on the previous occasions.

8th. Got up for an hour.

9th. [illegible]

13th.—Had a chop for dinner. Bowels opened by soap enema.

16th.—Truss fitted, and patient discharged well.

Remarks.—This was an uncomplicated case of strangulated femoral hernia in which no time was lost. The chief factor in determining an unfavourable result after strangulation is loss of time, during which the condition of the bowel is gradually deteriorating. Next to this Mr. Lucas maintains that injudicious taxis is responsible for more deaths than any other cause; and especially is this the case with femoral hernia, where the constrictions are usually tight and always very rigid. He has twice known the bowel ruptured by taxis for femoral hernia, and considering the knife-like edges presented by the saphenous opening and Gimbernat's ligament this is not to be wondered at. On the other hand, the risks of operation he regards as so trivial, that in the face of the danger of delay they should not be considered. When operating, he proceeds in the ordinary way by dividing the structures outside the sac, but should he succeed in reducing the bowel without opening the sac, he invariably proceeds to cut away the sac before closing the wound. The sac he regards as an abnormal structure to be eradicated without mercy; and he holds that by its removal many risks are avoided during the progress towards recovery, whilst at the same time a radical cure is effected.

CASE 3. *Strangulated Femoral Hernia in a Male; Operation for Reduction; Excision of the Sac; Suture of the Canal and Skin.*—C. O——, aged forty-two, was admitted into Job ward at 12 noon on Sept. 7th. He had suffered from right femoral hernia for four years, but had never worn a truss, reducing it himself when it came down. At 6.30 this morning it came down while at his work, and he was immediately seized with great pain, faintness, and cold sweats; he tried to reduce it, but could not do so, it being much larger than it had ever been before.

On admission the hernia was very tense, devoid of impulse on coughing, of the size of a pigeon's egg, and very painful. He had not been sick. Temperature 99°; pulse 120. Ice was applied for one hour, after which taxis was unsuccessfully tried; the patient was then put under chloroform and taxis again unsuccessfully employed for a short time. Mr. Lucas then made an incision over the tumour, and having come down on the sac, opened it, as the constriction was not external to it. Some bloody serum was let out, and the bowel was seen to be purplish-black and coated with clot. The constriction, which was at Gimbernat's ligament, was then divided, and the bowel returned. The sac was then excised, and the crural ring and canal sewn up with chromic catgut. The skin incision was sutured with wire, and antiseptic dressings applied. The patient was propped with pillows as in the preceding cases, and was ordered a one-grain pill of opium every six hours, and a pint of milk in the next twenty-four hours.

Sept. 8th.—Patient is quite comfortable; sleeps well. Opium omitted. Temperature 99·4°.

9th.—Temperature 99°. Wound dressed; looks well. Allowed one pint of milk and one of beef-tea.

10th.—Wound dressed; wire sutures removed.

13th.—Got up for an hour; bowels opened. Temperature 98·6°. Had a sole for dinner.

16th.—Bowels acting every day. Had mutton chop for dinner.

21st.—Went out, wearing a truss.

Remarks.—It will be observed in this case that though the bowel had been strangulated six hours, and was found at the time of the operation to be purplish-black in colour, coated with a thin layer of clot, and lying in a sac containing bloody serum, no vomiting had occurred before the operation. We had in this case but one symptom of strangulation—viz., an irreducible, painful hernial tumour devoid of impulse. The absence of vomiting was probably due to the strangulation having occurred before the man had broken his fast, and the pain and distress from which he suffered prevented him from taking anything after the bowel had come down. Doubtless, had injudicious friends primed him with brandy for the relief of pain, or given him castor oil for colic, vomiting would not have been long delayed. As it was, Mr. Lucas rightly regarded the one symptom sufficiently urgent to justify immediate operation. The bowel being reduced and the sac removed, progress towards recovery progressed without interruption. He sat up on the sixth day, and left the hospital well at the end of a fortnight.

NEWCASTLE INFIRMARY.

A CASE OF RUPTURE OF THE BLADDER; FRACTURE OF THE ASTRAGALUS AND OTHER BONES; POLYURIA. RECOVERY: REMARKS.

(Under the care of Dr. ARMSTRONG.)

WE are indebted to Mr. Frederic P. Maynard, M.B., house-surgeon, for the notes of the following case:—

Ellen D——, aged sixteen, a big, strong, stout girl, was admitted on Sept. 24th, 1886, having fallen forty feet from a window, her fall being broken by alighting on a man who was passing at the time. She was much collapsed, but soon rallied, and she was found to have sustained the following injuries when she was examined under chloroform:—Large hæmatoma of left cheek and orbit, right pupil dilated, left contracted, both reacting to light. Spinous process of twelfth dorsal vertebra fractured. Skin of arms grazed; no fractures. Right thigh and leg uninjured; os calcis fractured in two places, one transversely just in front of the epiphysis, which was drawn upwards by the gastrocnemii; and the other transversely further forwards. The astragalus was broken across its neck. Crepitus and mobility were easily obtainable between all these fractures, especially as the patient was under chloroform. The foot was pointed and swollen, the ankle appearing broader than natural. External malleolus of the left leg was broken and comminuted. The os calcis could be felt entire; astragalus broken across neck, where crepitus could easily be felt on flexing and extending the foot. The arch of the foot was flattened, and the foot lay with the toes pointed and everted. The abdomen was tender all over, especially above the pubes. No tympanites. There was a hæmatoma over the sacrum, and the whole perineum and both buttocks were black from bruising, but no wounds anywhere. Blood escaping from vagina. (Was regular, and menstruated one week ago; passed urine just before falling.)

A catheter was passed into the bladder, and two ounces and a half of dark bloody urine drawn off. The bladder was washed out with a warm solution of Condy's fluid. On passing a duck-billed speculum, there was found to be an irregular rent in the anterior wall of the vagina, four inches long, running obliquely upwards from right to left, and reaching below to within three-quarters of an inch of the meatus and above to the posterior fornix. The finger was passed through it into the bladder, but no other wound could be felt. The anal sphincter was relaxed; there was no wound of the rectum, which was full of feces. Coccyx uninjured. The vagina and bladder were washed out with perchloride of mercury solution (1 in 2000), and Mr. Maynard proceeded to sew up the wound in the bladder. At its upper end a Λ-shaped piece of mucous membrane was removed, to make the sides meet better, and twelve deep sutures altogether of silkworm-gut were introduced from above downwards by means of a curved needle set at right angles to the handle shaft. After again syringing, a plug of iodoform wool was placed in the vagina, and the bladder drained by means of a gum-elastic catheter tied in. At first the urine was bloody, but clear the next day. It contained traces of albumen until Oct. 1st, when it became normal. The legs were put up in splints.

Sept. 26th.—Temperature 101·8°; pulse 144. Has passed five pints five ounces of urine in the last twenty-four hours by catheter; it contains albumen, but no sugar.

27th.—Temperature and pulse still high; urine normal in quantity.

28th.—Temperature 102·4°; urine five pints six ounces; no sugar; tampon withdrawn and vagina examined; wound healing; edges rather everted between sutures, and ragged; upper portion of vaginal mucosa superficially sloughing.

Briefly, the temperature kept up until Oct. 5th, when all sloughs had come away (injections of Condy's fluid had been used frequently), and the urine became normal, and subnormal in quantity. On the 19th the last suture was removed, and the bladder found firmly united, no urine ever having passed through it. The splints were left off the legs, and some movement was obtainable in both feet. On the 25th the girl was in every way well, the feet improving in movement daily, and micturition and urine being normal.

Remarks.—This appears to be a case—very rare—of rupture of the bladder, when empty, from indirect violence. The momentum of the heavy uterus (she was a big girl, and the uterus was also large) when her fall was broken by the man she alighted upon, would force it down upon the perineum, and probably ruptured the vesico-vaginal septum, and by the stretching of its ligaments caused the great abdominal pain and tenderness. There were no signs of any instrument, sharp or blunt, having wounded the vagina, though there certainly was general bruising of the nates and perineum. The polyuria was of interest, inasmuch as there was no glycosuria. There was a blow over the left orbit and cheek, which may be supposed to have caused some cerebral mischief. The fracture of the astragalus *alone* in the left foot is a very rare condition. Monahan records ten cases, and Erichsen refers to two in his own experience, though one of his was accompanied by a most peculiar deformity, and there was no injury to the malleolar arch.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Disseminated Myelitis and Measles.—Acute Tubercular Ulceration of the Larynx.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Dr. THOMAS BARLOW read a paper on a case of early Disseminated Myelitis occurring in the Exanthem stage of Measles, and fatal on the eleventh day of that disease. The patient, a policeman, aged twenty-three, was admitted at the London Fever Hospital on June 11th, 1885, suffering from measles—the second day of the rash. There was nothing special about his case, except that he complained of soreness down the breast-bone and at the epigastrium. At midnight on the 13th there was retention of urine. On the 14th he was drowsy, but intelligent when roused. There was paralysis of the lower limbs, with loss of knee-jerk and of plantar reflex; but the patient was able to localise a pinch on either leg. The grasp of both hands was weak. There was still retention of urine. On the 15th the patient's mental state was quite clear, but in every other respect he was worse. He could only speak in a whisper; his cough was ineffectual. He complained, as on admission, of fixed pain down the breast-bone and at the epigastrium. The paralysis of the lower limbs, absence of knee-jerk and retention of urine continued; the weakness of grasp in the hands was more marked, and the intercostals were paralysed. There was slight deviation of the tongue to the left. The patient gradually become cyanosed, and died on the evening of the 16th, which was the eleventh day from the onset of measles. The post-mortem examination, beyond consolidation of the lower lobe of the left lung and intense congestion, with ecchymoses of the tracheal and bronchial mucous membranes, showed no important visceral changes. In the brain the grey matter of the convolutions was darker than natural, and the brain substance unduly soft. The ependyma of the lateral ventricles was easily detached. The spinal cord showed extensive softening in the upper dorsal region. Opposite the fifth dorsal vertebra the cord was quite diffluent. There was also red softening in the lumbar region, most marked in the grey cornua, which at some spots were quite tunnelled. Microscopic examination of the cord, made by Dr. Penrose, showed that the changes were mostly vascular, consisting of great engorgement of vessels, infiltration of surrounding tissues with leucocytes, and slight interstitial extravasation of blood. No changes were found in the nerve-cells, fibres, or supporting tissues of the cord. In the medulla oblongata very similar changes to those present in the cord were found, with the exception that no hæmorrhages had occurred. The stress seemed to have fallen chiefly on the hypoglossal and vagus nuclei. The case was recorded because (1) accounts of the post-mortem appearances in fatal measles with nervous complication were very rare; (2) because it had considerable resemblance to a fatal case of disseminated myelitis after small-pox recorded by Westphal; (3) because it possibly threw some light on the changes which give rise to certain groups of cerebro-spinal symptoms left after some of the fevers, especially those allied to multiple sclerosis to which Westphal first drew attention.—Dr. [illegible] referred to a case of cerebro-spinal [illegible] measles almost as closely as [illegible] began [illegible]

Oct. 14th, the rash came out on Oct. 18th, and the signs of meningitis appeared on the 24th. There were opisthotonos and rigidity of limbs, with marked vaso-motor phenomena and a very high temperature, during the early stage. It was possible that such a poison as that of measles could lead to the occurrence of myelitis and meningitis, for it certainly could cause diphtheritic disease. He asked whether in the severe measles that affected islands like Fiji there were any spinal lesions?—Dr. S. WILKS spoke of the relation of various secondary affections of the nervous system to acute specific fevers. Sometimes they were sequelæ, but at others they were concurrent. Cases of paraplegia occurring in connexion with typhoid fever might be mere coincidences, or the symptoms might follow on the disease. He objected strongly to the notion of reflex paraplegia from typhoid fever, the paralysis being ascribed to the afferent influence of ulcerated intestines on the spinal cord. It was satisfactory to find that cases did occur in which actual organic lesions were to be found as explaining the occurrence of the paralysis. Sometimes there was no acute specific fever at all, but the case from the first was one of myelitis, the other febrile symptoms being due to the nervous lesion.—Dr. ORMEROD mentioned cases of paralysis which began at a clear interval of about a month after measles. Three members of a family, the father, son, and daughter, were the subjects of the diseases; but they were affected in different epidemics of measles. The paralysis began with turning in of the foot, followed by wasting of muscles of the leg. The gradual onset was unlike infantile palsy. In one case the paralysis progressed, and began to affect the hands. Reference was made to a paper by Dr. H. Tooth on the peroneal type of progressive muscular atrophy. It was important in these cases of nervous disease to recognise the two factors—viz., measles and family disposition. It was the same in hereditary ataxy, in several cases of which there was a history of distinct acute disease. Whether the cases first referred to were examples of progressive myelitis or peripheral neuritis due to measles poison he was not prepared to say.—Dr. G. V. POORE was interested in the explanation of the initial symptom of pain down the breast-bone. It was probably of spinal origin, and the region of the fifth dorsal nerve, where the disease reached its greatest intensity, would be the part of the cord corresponding to the seat of the pain. There seemed no doubt that the myelitis and measles ran concurrently. He asked whether there was any history of a blow on the back.—Dr. BEEVOR remarked on the rapidity with which the disease runs its course. He mentioned a case of myelitis which terminated fatally in five days; the paralysis began in the legs; the microscopic changes were much the same as those met with in Dr. Barlow's case.—Dr. BARLOW said that Dr. Cheadle's case was interesting as occurring within the exanthem period of measles. He thought it was important that the diseases should be classified according to the period at which the nervous symptoms commenced. In his own case Dr. Barlow believed that the spinal affection was as much a part of the measles as the skin rash and the bronchial catarrh. The cases referred to by Dr. Ormerod were interesting, and he had also seen two children affected in the same way. The family predisposition and the acute specific disease were important etiological factors. There were many recorded cases of acute ascending paralysis occurring in connexion with acute specific fevers, in which no kind of lesion could be found. Nothing could be learnt of any traumatic influence in the case described; but the exposure to weather incident to a policeman's life may have had some share in the causation of the myelitis.

Dr. J. ABERCROMBIE and Dr. GAY read a conjoint paper on three cases of Acute Tubercular Ulceration of the Fauces. The authors related three cases of acute tuberculosis in children in which ulceration of the fauces occurred within a few days or weeks of death. In one of these cases the ulceration was shown by microscopical examination to be tubercular. In the other two there was no reason to doubt that it was of the same nature. Pain in the throat and dysphagia were the only premonitory symptoms of this affection, soon followed by the development of whitish punctiform spots, about the size of a pin's head, on the soft palate, uvula, or tonsils. In the course of a very few days these spots enlarged and coalesced, subsequently breaking down and leaving variously shaped irregular superficial ulcers. The ulceration may spread until the whole of the fauces are involved. The death of the patient usually occurs before the ulcer[illegible]ead. Generally the fauces are [illegible] with a viscid secretion, which greatly adds to the difficulty of diagnosis. The usual symptoms of acute tuberculosis will be present, especially the fever and emaciation, but the other signs of the disease are often masked. There is usually, but not always, considerable enlargement of the glands of the neck, and these may suppurate. The differential diagnosis of this affection from diphtheria, tonsillitis, and syphilitic affections of the throat was briefly discussed. The authors regard this form of angina as only a part of general tuberculosis, in which respect it differs entirely from the chronic tubercular ulceration of the fauces, which is either primary in the pharynx or spreads there from the larynx. The disease always proves fatal, though the patients do not usually or necessarily die from the throat affection.—Dr. PERCY KIDD could not agree that there was any actual distinction between acute and chronic forms. The disease might spring from the larynx or was primary, but it should not be lost sight of that the expectoration from the lung might be the source of it. Of 500 necropsies, he had met with six or eight cases of tubercular disease of the pharynx. Sometimes the disease began as minute whitish specks, followed by ulceration, and this only one month before a fatal termination. Herpetic vesicles on the pharynx might cause some difficulty in diagnosis for a time; so that diphtheria was not the only disease for which tubercle of the pharynx could be mistaken.—Dr. ABERCROMBIE thought there would not be much difficulty in distinguishing the acute from the chronic. In some cases the ulceration was secondary to the appearance of whitish spots or nodules. He was under the impression that in pharyngeal herpes there was also herpes about the mouth, so they had left it out of consideration.

MEDICAL SOCIETY OF LONDON.

Spontaneous Uterine Rupture.—Hepatico-bronchial Fistula.—Iodide Rash.

AN ordinary meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Dr. A. H. N. LEWERS read a paper on Rupture of the Uterus during Gestation. It was an accident of rare occurrence, and its causation was but little understood. A study of nineteen recorded cases led Dr. Lewers to express the opinion that "spontaneous" rupture during pregnancy was invariably due to "interstitial" gestation. He described a case that occurred in his own practice at the London Hospital, in which a multipara, believed by herself to be in the fifth month of gestation, suddenly became ill with severe pain in the abdomen, vomiting, and collapse. Abdominal section was performed, and then the fœtus and placenta were discovered in the peritoneal cavity, and a rent in the fundus of the uterus was detected at the outer part on the left side. The post-mortem examination showed that the rent in the uterus involved that part of the wall through which the left Fallopian tube passed. The case was not one, therefore, of genuine rupture of the uterus, for the fœtus had never occupied the uterine cavity. Dr. Lewers considered that spontaneous ruptures of the uterus attributed to pathological softening of the wall were of doubtful occurrence. He thought, also, that cases of genuine spontaneous rupture should be kept apart, and not placed in the same category as those where rupture of the uterus occurred during premature labour, or in criminal attempts at the production of abortion, or from direct violence. There was nothing in the records of cases of spontaneous rupture to militate against the suggestion he desired to make—that spontaneous uterine ruptures are invariably cases of "interstitial" gestation. He submitted that where the symptoms pointed clearly to the occurrence of the accident exploration of the abdomen was the correct surgical treatment.—Dr. BRAXTON HICKS made some remarks on accidental hæmorrhage, having symptoms like those met with in rupture of the uterus.—Dr. JOHN PHILLIPS remarked that the fœtus in Dr. Lewers' case measured eight inches in length, but the rent in the uterus did not seem to be large enough to admit of the exit of so large a fœtus.—Dr. C. H. F. ROUTH described a case of rupture from his own practice, and congratulated Dr. Lewers on his paper, which contained a valuable suggestion.—Dr. LEWERS said that in the case mentioned by Dr. Hicks the hæmorrhage occurred so late in pregnancy as to place it in a different sphere from those cases to which his paper drew attention.

DR. DE HAVILLAND HALL read notes of a case of Hepatico-bronchial Fistula occurring in a meat salesman, who suffered much pain in the hepatic region, followed by jaundice three weeks before he was seen. Vomiting of bright bile also occurred. An enormous quantity of bilious fluid was brought up at one time. The liver was enlarged, not tender; the urine was loaded with bile, the motions pale, and the patient jaundiced. The discharge of bilious fluid was continued, and it was evident that the bile came from the lung, as it was expelled by coughing and was frothy. The patient eventually recovered. Dr. Hall quoted Trousseau, Goodeve, Frerichs, and Murchison to show the rarity of the affection. The first case reported was one in THE LANCET by Mr. W. E. Green, July 6th, 1878. The second was one by M. Laboulbène to the Société Médicale des Hôpitaux, Aug. 1875. The third was recorded by Dr. Dreschfeld in THE LANCET, vol. ii. 1879, p. 867. Dr. Hall pointed out that in the majority of cases hitherto recorded hepatico-bronchial fistulæ had been caused either by the rupture of an abscess or of a hydatid cyst in the liver, and the discharge of their contents into the lung; but from the result of his investigations he would add the impaction of a gall-stone and consequent dilatation of the bile ducts as another cause of these fistulæ. In taking a grave view of the prognosis in these cases, Dr. Hall pointed out that two of the four cases to which he referred ultimately died. He stated that the treatment must necessarily be of an expectant kind. If there were complete obstruction to the entrance of bile into the intestine, the purified ox bile of the British Pharmacopœia might be given with advantage. Should there be any difficulty in clearing the lung of the bilious fluid, a stimulating emetic, such as ten grains of carbonate of ammonium and twenty grains of ipecacuanha, might be required. The question of surgical interference might come into question if bile accumulated in the pleural cavity. A bibliography was appended to the paper.—The PRESIDENT thought that medical officers of Netley could add largely to the number of cases of hepatico-bronchial fistula.—Dr. LOWE mentioned a case of the kind which turned out to be hydatids; it occurred in a young man, a fisherman.—Dr. SANSOM and Dr. S. WEST also joined in the discussion.

Dr. SAMUEL WEST showed a coloured drawing of a case of Iodide Rash, taken from a man aged sixty-seven. The eruption began as vesicles, which increased in size and became purulent. A sanguineous exudation escaped when the blebs were ruptured. The forehead and face were the chief seats of the eruption.—Dr. C. H. F. ROUTH and Dr. DE HAVILLAND HALL and Mr. J. H. MORGAN joined in the discussion.—Dr. SANSON mentioned a case of fatal iodic purpura from the administration of syrup of iodide of iron. —The PRESIDENT said that minute doses might be borne where the ordinary dose caused iodism.

HARVEIAN SOCIETY.

Etiology of Hydramnios.—Alpine Winter Climates.

A MEETING of this Society was held on Thursday, Oct. 21st, J. Hughlings Jackson, F.R.S., President, in the chair.

A specimen of Supra-vaginal Amputation of the Cervix Uteri was exhibited by Dr. Lewers. The operation had been performed for malignant disease in July last, by means of scissors, with satisfactory results to the present time.

Dr. JOHN PHILLIPS read a paper on the Etiology of Hydramnios and its relation to certain Fœtal Deformities, commencing with a brief sketch of the mode of development of the amnion and its structure, the variable composition of the amniotic fluid at different periods of pregnancy, and the presence in it of urea. The following three views were at present held in the etiology of the disease:—1. That the amniotic fluid is a product of fœtal origin (Lallinger). 2. That it is the product of the maternal organism (Ahlfeld, Scanzoni, and Schroeder). 3. That it is a common product of fœtal and maternal origin (Virchow). The theory that the fluid is a transudation of the liquid parts of the fœtal blood across the amniotic membrane was dilated upon at some length. It was concluded that the cause of the secretion was probably due to resistance met with by the fœtal circulation in the placenta or cord; the greater the resistance the larger the amount of the hydramnios. The cord and amnion were given as the means of escape by exosmosis of the fluid, and their histological structure briefly described. Ahlfeld's theory that the cause is to be found in the modification of pressure which the uterus undergoes in the progress of pregnancy was upheld for the first three months of that condition. The frequent connexion between hydramnios and turning was then discussed. The author concluded his paper by giving the various groups of fœtal malformations, calling attention to exaggerated tension of the cord, umbilical venous thrombosis, and varicosities, as having a large share in the causation of the disease. Microscopic specimens were exhibited.—Dr. ALDERSON referred to the length and twisting of the cord as a cause of hydramnios, and noted that the mother in such cases had generally taken but little exercise.—Dr. C. GOOD had met with cases of congenital cystic kidney, hydronephrosis, cystic liver, and even hydrocephalus, without any hydramnios. He thought that the cause of the fluid was not yet proven.—Mr. GRIFFITH remarked that fœtal urine was not understood even by experienced chemists, and the existence of urea in the fluid had been denied by Odling. The quantity of amniotic fluid varied in ordinary cases with the length and number of twists of the cord, but in hydramnios the cord was generally shorter than normal. —Mr. CRIPPS LAWRENCE laid stress upon the method of insertion of the cord and called attention to intra-uterine amputation of limbs by strangulation.—Dr. MORTON mentioned cases of early rupture of membranes, the secretion of fluid continuing until delivery. These seemed to prove that the membrane must have secretive powers.—Dr. ROUTH pointed out that hydramnios usually occurred about the fifth month, and hence could not be due to renal secretions. —Dr. PHILLIPS replied.

Dr. TUCKER WISE read a paper on Alpine Winter Climates, in which he described the various out-door exercises and sports indulged in by patients seeking health in the High Alps. He considered that judgment was necessary in the selection of cases for the mountain climates, but did not limit the benefit of winter residence to cases of consumption only. Patients frequently arrived in the Alps on their own responsibility and even in opposition to medical advice, and this sometimes led to results which caused gross misunderstanding regarding the climates. Under the influence of the sun's rays and dry air the sensation of cold in the Alps was out of all proportion to the pitch of the thermometer; A low temperature that would be chilling and dangerous to delicate persons in England was apparently borne with comfort in the Alpine snow regions. The great importance of sanitation and uniformity in warming hotels inhabited by invalids was dwelt on, and especially the supply of pure air within doors. The following conditions were deemed unsuitable for winter residence: (1) diseases of the brain, heart, or large vessels; (2) tendency to articular rheumatism; (3) kidney diseases; (4) acute inflammation of throat or larynx; (5) some diseases of the bladder or prostate; (6) neuroses or vascular excitement; (7) hysteria; (8) persons of advanced age, unless the circulatory apparatus were sound; and (9) extreme emphysema. It was not possible, however, to lay down any hard-and-fast rules.—Dr. SYMES THOMPSON spoke very highly, from personal experience, of the good effects of the Alpine winter climate. He should not be inclined to include throat cases amongst those generally unsuitable. Even laryngeal phthisis had occasionally been benefited. In most throat conditions the continuous inhalation of dry air was useful. The increase of smoke at most of the popular health-resorts was becoming a serious consideration. As a general rule, patients unable to walk about should not be sent to the high altitudes. Dr. EWART believed that almost all classes of cases obtained some benefit, and certainly he had seen good results in cases of nerve exhaustion. More information was wanted with respect to the selection of climates suitable to different stages of disease. Cases of pharyngeal disease where the mucous membrane was always moist, and especially adenoid growths in the naso-pharynx, usually did well in dry air. Pharyngeal deafness also was often much relieved at high altitudes.—Dr. WISE replied.

ASSOCIATION OF PUBLIC SANITARY INSPECTORS.—The annual address of the Chairman of this Association, Mr. G. B. Jerram, was delivered on the 6th inst. The subject of the address (the practical importance of which to the public cannot be exaggerated) was on the Best Materials and Methods of Construction of Drain-pipes, and the most efficient means of making Joints impermeable to Gas and Water. A discussion, in which several members joined followed the de[illegible]

Reviews and Notices of Books.

A Manual of Midwifery. By A. L. GALABIN, M.D. London: J. and A. Churchill. 1886.

THE writer of a manual of midwifery has a difficult task before him; he must possess a wide and accurate knowledge of the literature of the subject, and extensive experience of its practice; on the other hand, he must possess decision of character, and the qualities which constitute a "strong judge," qualities which enable him to weigh facts for himself, to come to a definite conclusion, and, having done so, to state his results with a healthy dogmatism. As a corollary to this last quality, he must possess a keen nose for quackery, and courage to reject it. In the interest of the student, he must not only relentlessly separate the grain from the chaff, but must not hesitate to ruthlessly destroy the chaff. The present work is the lineal successor of the excellent manual of Tyler Smith, but our author in 1886 has a far more difficult task than Dr. Tyler Smith had in 1849 and 1858, on account of the large amount of new work done since that time; to keep the volume down to nearly its original bulk, he has to exercise a nice judgment as to the space to be assigned to each subject. It will be our task to endeavour to estimate the present work on the above principles.

The chapter on the Anatomy of the Pelvis is generally good and lucid; we think, however, that the measures given are too minute. Small decimals are of no importance practically, seeing that they cannot be accurately measured in the living woman, and there is no such thing as a normal pelvis.

The chapter on Ovulation and Conception is also generally good and clear. We regret, however, to see that our author has included within it statements which are, in our opinion, unproved, and have given occasion to a large number of unnecessary operations. We refer to the explanation of the mechanism of impregnation given on p. 46. If these are our author's definite conclusions, we are sorry for it; if they are not (and we seem to detect a certain hesitation in their enunciation), we regret that he should be, or appear to be, capable of being quoted as an upholder of these views, and implicitly as an approver of the practices founded on them. The remaining chapters on Development are good, but Fig. 40 (p. 66) contains a serious error, as it professes to show the chorion stripped off the fœtal part of the placenta as far as the umbilical cord.

The chapter on the Management of Normal Labour (one of the most important for the student and practitioner) is one of the least satisfactory in the book, and does not bear the impress of familiarity with the details of the subject which we should have expected from one in the author's position. The directions are often incomplete and vague, and the subject of antiseptics is dealt with so imperfectly that it had almost better have been omitted. In any subsequent edition the space assigned to some of the more lengthy and less important subjects might well be transferred hither. Manual dilatation of the perineum, recommended at p. 196, is in our view objectionable. The rules for the expulsion of the trunk (on the same page) might be improved. The author says it should be assisted "if the child is in danger of asphyxia." Under what circumstances this danger is present he does not say. There is no word to the effect that under ordinary conditions a child may live with its head alone in the world for an indefinite period; and this is an important point, for the tendency of the ignorant is to hurry. The eyes should also surely be wiped with a clean napkin at once. The importance of thrombi (p. 199) for the arrest of hæmorrhage, is very doubtful. The examination of the placenta (—— ——ory, and should be greatly enlarged. The perineum is better examined by the eyes than by the fingers (*ibid.*) in our opinion, and the introduction of the fingers into the vagina after the birth of the child (*ibid.*), is not a practice to be recommended. The directions for the application of the binder (p. 201) might be improved; students require accurate instruction in this matter, and these directions will, we fear, result in a good deal of wrinkling and riding up. The direction to repair the perineum without an anæsthetic, founded on a fear of hæmorrhage is, in our experience, quite unnecessary in ordinary cases; and, if so, it must be remembered that a little pain *after* delivery is never forgotten by a woman, while she soon forgets all that has gone *before*.

In the description of Face Presentations (p. 209) the author names them by the *forehead* rather than the chin. This seems to us a mistake, inasmuch as the mechanism of face cases is almost identical with that of vertex cases, if it is only remembered that the chin represents the occiput, and the easiest statement is always preferable to the harder, if both are correct. In the chapter on Pelvic Presentations, the paragraph relating to dorso-posterior positions (p. 226) does not include the mechanism of the shoulders, which is peculiar and by no means to be taken for granted. We are glad to see (p. 227) that the chief danger to the child is stated to be abolition of the placental circulation, rather than pressure on the cord.

The chapter on the Management of the Puerperal State contains several pieces of advice with which (we may be old-fashioned) we do not agree: among these are feeding a patient soon after labour with fish, chicken, or meat; the recommendation to insist on a woman nursing her child for at least the first four or six weeks, "even if the milk is deficient in quantity or poor in quality"; under these circumstances the child, in our experience, generally suffers, and is far better brought up by a wet-nurse. On the next page it is recommended that both breasts be used at each time of nursing. We think this is not good advice; the breasts are liable to be imperfectly emptied and the nursing powers to suffer. Moist dressing is recommended for the cord; it has, we think, been proved that dry treatment (the usual treatment) is best and safest. Again, four parts of water to one of condensed milk is too strong a mixture—at least to start with.

In the chapter on the Vomiting of Pregnancy we find among the exciting causes "inflammation of the cervix and grave displacement." We are sorry to find our author directing the student to the cervix for the cure of this complaint. As to the "grave displacement," we say the same; and we do not quite gather whether Dr. Galabin has really made up his mind on the latter point, for on p. 300 we read that retroversion of the gravid uterus is by far the gravest displacement of the pregnant uterus. This is no doubt true, and yet in this condition where is the aggravation of the vomiting? Is not this an absolute disproof of the hypothesis?

The subject of Eclampsia is always a difficulty. We do not yet know the pathology of the affection; but the student will, we fear, in the chapter devoted to it, be confused with details, and will miss the strong guidance in the right direction which he will look for. In the differential diagnosis we see nothing about epilepsy, from which eclampsia has not seldom to be distinguished. The author decries bleeding, which has, in our opinion, been too much neglected [illegible] he suitable cases.

No part of a treatise on midwifery is of more importance than that concerning Placenta Prævia. The chapter on this subject in the volume before us is disappointing. We fail to gather the treatment recommended: on p. 382 we are advised to dilate the cervix with a sponge tent, then with hydrostatic dilators, then to puncture the membranes; on

p. 384 to "puncture the membranes as soon as they can be reached"; on the same page, lower down, to dilate "until the os is large enough to allow either the passage of the fœtus or the performance of version, according to the circumstances of the case"; on the next page, "the performance of version has long been the traditional treatment for placenta prævia, and is still the most effectual means of finally checking the hæmorrhage." It is not, however, bipolar version, for we read below a caution against tearing the cervix by forcing in the *hand* too hastily. On p. 386, "to recapitulate," the following order of treatment is recommended—(1) Partial separation of the placenta; (2) if necessary, plugging; (3) leave the case to nature, or use forceps, or use version. What our author really means we cannot make out. We are also surprised to find no trace of the work done on the subject during the last three years, especially in Berlin, which has simplified the treatment to a very great extent. It would, in our opinion, have been worth all the discussion before us to teach the student plainly that in placenta prævia the great treatment is bipolar turning as soon as two fingers can be introduced, that the bleeding ceases on turning and before extraction, and that extraction can be generally omitted with advantage.

The chapters on Pelvic Deformities are excellent; great use is made of the modern teaching with regard to the "pressure of the femora," to which we shall refer, and which contributes greatly to the elucidation of the problems. We shall only point out one or two small matters that seem to us debatable. On p. 485, treating of the effects of pelvic contraction on labour, our author says, "The uterine wall being more stimulated than usual by the pressure of the fœtus, the pains quickly assume an expulsive character." This seems to us generally to depend on the nature of the contraction: in contraction of the brim the head is often held up so high that it cannot stimulate the lower uterine segment; in contraction of the outlet the head is able to press through on the lower uterine segment, and to stimulate it. The chances of success in inducing labour depend, in our experience, largely on this point. In a note on p. 490, it is said that Dr. Matthews Duncan found that the neck of the fœtus gave way under tension of 80 lb., or a little more. The correct weight is 100 lb., not 80 lb.

The chapter on the Forceps is excellent; it includes a plea for the vectis in face-to-pubes cases which sounds very reasonable. These are awkward cases, and treatment by forceps is often unsatisfactory. We do not fancy the pattern of forceps recommended by the author, which seems a compound of three or four different patterns; the flanges get in the way and are clumsy, and the digitations on the handles hurt the hands. On p. 557 we are told that "it is now the usual plan, even if straight forceps are used, not to pay much regard to the position of the head, but apply the blades at each side of the pelvis." No doubt it is the rule in long forceps cases to apply the blades to the sides of the pelvis; still, we think it most important that the position of the head should be borne in mind. The forceps nearly always lies a little obliquely, and its obliquity must either favour or impede the rotation of the head; it is therefore important that its obliquity should be in the right and not in the wrong direction. The explanation of the exertion of axis traction by ordinary long forceps (first recommended, as far as we remember, by Oslander) is good; in practice we have found the forceps apt to slip backwards if used in this way. In dealing with occipito-posterior cases, we think it is well to recommend traction with the forceps, while rotation is promoted by pressure on the anterior lying temporal region.

The chapter on Version is also very good. The author recommends seizing the knee in bipolar turning; we think this limits the operation. It is sometimes quite easy to turn through a cervix barely admitting two fingers, and through which a small fœtal foot passes with great difficulty; a cervix large enough for the knee to pass easily is already on the road to sufficient dilatation for ordinary internal version.

The chapter on Craniotomy &c. is good. We cannot say the same for that on Cæsarean Section; the chapter might have been written three or four years ago, and before the description of any of the recent improvements by Sänger and others, which have raised grave doubts as to the inferiority of the old operation, if done with care and attention to minute details. This is an unaccountable omission in a book which generally bears the mark of good contemporary knowledge. Our author is apparently a sincere believer in the train of ills said by our transatlantic brethren to follow lacerations of the cervix; we confess we do not come across these cases.

Another chapter which we shall mention is that on Puerperal Fevers. This occupies nearly fifty pages, but is not, to our mind, successful. To begin with, our author's inferences are founded chiefly on "Collective Investigation Reports," which are quite unsuitable for settling questions of this nature. It is impossible to get unity; the information is largely founded on impressions, and those who remember the great difficulty attending the unravelling of even a single case of puerperal fever will, without in any way impugning the integrity of the informants, hesitate to accept the conclusions founded on evidence so multiform. We will put the main question in a nutshell. If the "autogenetic" form (so-called) is "much the more common" (p. 715), how is it that antiseptics have entirely put an end to epidemics of puerperal fever in lying-in hospitals. As regards scarlatina, we can only say that the believers in this as a great source of puerperal fever require so many variations as to rash, throat, and other ordinary symptoms, so many peculiarities as to incubation, to be believed by us, that we are entirely sceptical on the point. What we want is an accurate analysis of a series of cases of scarlet fever observed in lying-in hospitals. If these should show that scarlet fever is always scarlet fever, the whole theory of puerperal scarlatina would, in our opinion, become untenable. With regard to the question of abstention from practice after a case of puerperal fever, our author advises the practitioner to give up practice "for a time"—i.e., "at least a week"; if he has conveyed infection to another patient, then as long as two or three weeks. In a note on the same page (p. 737), however, he quotes a case of his own to prove the safety of attendance after careful disinfection. We agree with the note, and not with the advice given in the text. If our author abstains from practice according to his own advice (and the note seems to show that he does not), he is probably the only person in obstetric practice who does so. Time we believe to be no safeguard; careful disinfection we believe to be all-sufficient. To recommend abstention from practice is not only at variance with the facts of the case—it is, if anything, a mere concession to Mrs. Grundy, who is apt to demand more and more if unreasonable concessions are granted her. To abstain from practice without disinfection is useless; to disinfect *and* abstain is certainly unnecessary. In lying-in hospitals a separate room is recommended for each patient. We do not believe this would be of much use unless each patient has a separate nurse, and this is in most cases quite unnecessary. In a well-managed hospital no patient is ever infected from another. As regards treatment, our author rightly prefers the irrigator, which acts by gravitation, to the Higginson's syringe, which acts by intermittent squeezing; but we think the latter is preferable to the common syringe recommended (p. 742) as the second best. Nor need a Higginson's syringe, if well made and carefully used, carry air. We do not endorse the advice given on p. 743 to puncture distended coils of intestines.

In the chapter on Phlegmasia Dolens the disease is described as probably of septic origin. This seems to us unlikely in the face of the almost certainly good prognosis of the complaint.

The proofs have clearly been revised with great care, and printer's errors are rare. We have noted a few of the more important clerical and grammatical mistakes: "Dolores cruentæ" (p. 154)—"dolor" is masculine; "pubes" (p. 44) is a singular and not a plural noun; "forceps" is a singular collective noun, and means a pair of tongs or pincers; "labiæ" (p. 654) should be "labia," from "labium" (singular); "weed" (p. 248)—an affection we do not believe in—should be spelt "weid"; "scarletina" (p. 349) is probably intentional, though peculiar—it occurs frequently, and is always spelt the same.

We have referred to two instances in which Dr. Galabin has missed good work recently published, but we must now refer to mistakes of another sort. In some instances the author has made serious omissions of reference. An instance of the kind occurs on p. 23, with regard to the explanation of pelvic deformities. In 1883 Dr. Champneys pointed out that the pressure of the femora was outwards; until that time it was believed to be inwards; this view, first brought out by Dr. Champneys, has changed our theories of the production of pelvic deformities. On the page of this work above mentioned, Dr. Champneys' ideas, and almost his words, are adopted, and the idea is used throughout to explain pelvic deformities, but without acknowledgment, although the names of other writers on the subject are mentioned. In justice to the propounder of this view, and as a guide to the reader, proper reference to the original source of it should have been made.

In conclusion, we may describe the book before us as the work of a first-rate mechanician and of an obstetric physician extremely well read in the literature of his subject; the exceptions above mentioned do not prove the contrary. The language is lucid and natural, and the best chapters are excellent; we have indicated them above. Our author is at his best when clearly elucidating a mechanical problem; as a strong and fearless guide to the student and practitioner in the ethics of daily practice he is far less satisfactory. A teacher should be one to "strengthen the weak hands and confirm the feeble knees"; to brush away cobwebs relentlessly, and to refrain not from flinging a stone at quackery. Of these qualities we find no trace in the present work; with the addition of these qualities our author would have produced a work worthy to rank with the best English manuals of midwifery. Where these qualities are not required, the work is generally capital; where they are necessary, it disappoints us.

Paralysis from Peripheral Neuritis. By THOMAS BUZZARD, M.D., F.R.C.P. London: J. and A. Churchill. 1886.

THE profession will be thankful to Dr. Buzzard for issuing his Harveian Lectures in a separate form. The subject of peripheral neuritis is of such recent growth, and has such wide bearings in neurology, that the bulk of the profession has not yet had time to become acquainted with its teachings and bearings. The full title of Dr. Buzzard's lectures is: "Some Forms of Paralysis from Peripheral Neuritis—of Gouty, Alcoholic, Diphtheritic, and other origin." In these lectures the profession will find a very useful summary of our knowledge of the subject, together with accounts of many original cases that have come under the author's cognisance.

Our Dress and our Food in relation to Health. By D. EDGAR FLINN, F.R.C.S. Dublin: M. H. Gill and Son. 1886.

This little book, popularly written and compiled from a series of lectures, contains a few clear simple hints as to the arrangement of [illegible] of food. It touches lightly on fashions past and present in regard to their bearing on the subject of health, and denounces emphatically the injurious systems of tight-lacing and high heels. The author recommends woollen materials for wear, on account of their warmth and porosity, favouring the escape of perspiration. Next in order he places cotton-cloth; and then silk, which has the advantage of lightness. The weight of the present style of dress is condemned, both from a hygienic and artistic point of view, since it does not allow the limbs free play. The hints on food, the process by which it is digested, and the degrees of nutrition contained respectively in various articles of diet, may be useful to the general public. The author insists on the necessity of "variety" for the maintenance of health.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A LARGELY attended meeting of Fellows and Members was held on the 4th inst. at the College, for the purpose of considering the report of the Council, together with the resolutions, of which notice had been given on behalf of the Associations of Fellows and Members.

The PRESIDENT (Mr. W. S. Savory), in opening the proceedings, said the report that was in their hands contained so full a record of the Transactions of the Council for the year ending July last that he need not detain them by any additional remarks upon the subject. They would see that, in addition to the ordinary work of the year in all matters relating to the general conduct of the College, the time and attention of the Council had been largely occupied with two or three very important subjects. In the first place, there had been, and still existed, the great duty of making all necessary arrangements and appointments for the efficient working of the Examining Board under the Conjoint Scheme with the College of Physicians, and no doubt they had all looked with interest to the progress which the new Examination Hall was making towards completion. The new scheme was full of promise for the future. Then there was the exciting question whether any practicable and worthy plan could be devised by which the Colleges might be enabled to provide those who passed their examinations with degrees in Medicine and Surgery. (Cheers.) And, lastly, there were recent arrangements for widening or modifying conditions of admission to the Fellowship. There had been, and still was, abundant material for the work of the Council, and he was sure he might say it was with pleasure that the Council placed their report in the hands of the Fellows and Members.

Mr. TIMOTHY HOLMES then moved the first resolution:—"That in the opinion of this meeting it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education, (1) if Members of the College were empowered to take part (separately or conjointly with the Fellows) in the election of members of the Council; (2) if Members of the College were eligible to sit in the Council, provided (*a*) that no Member of the College shall be entitled to vote till he have been such Member for a period of ten years, (*b*) that no Member of the College shall be eligible to sit in the Council till he have been such Member for a period of twenty years, and (*c*) that not more than one-fourth of the Council shall consist of Members of the College who are not also Fellows." He said it was with very great pleasure that he and all those to whom the report was addressed must acknowledge its courteous and conciliatory tone, and it was with still greater pleasure that they acknowledged the great progress which the College had made in coming forward—he hoped he might say annually—to meet the Members and Fellows in consultation. (Cheers.) There were several matters in which the business of the College had very considerably changed in the sense in which those who were acting with him desired that it should change, and, in one matter especially, to which he hoped he might refer without impertinence—he meant Mr. Savory's presence in the chair. (Cheers.) They felt that the practice which used to prevail of handing the presidency, as it were, round the council-table was one which diminished the dignity of the office, and was not

favourable to the efficiency of the College. They were delighted to see that a change had been made in that routine, and that in the first instance the choice of re-election had fallen upon so worthy a representative of British surgery. (Cheers.) He observed by the report that the Council stated that on questions concerning the constitution of the College they would always be glad to have an opportunity, as far as practicable, of consulting the Fellows and Members. The idea of giving medical and surgical degrees by the diplomas of the united Colleges was a matter which touched the medical profession so very nearly that they had the strongest reason to thank the Council for their implied promise that the Fellows and Members would be consulted upon that subject before any definite action was taken. (Cheers.) This would apply still more strongly to the proposition for the inclusion of the Society of Apothecaries in the Conjoint Scheme. On these matters the Council had by implication promised to consult what he was going to call their constituency—what he hoped would be their constituency. (Cheers.) For this they had nothing but thanks to give, and to express the hope that the Council would persevere in the course of reform which for a long time appeared to be impossible. The report also stated that "the Council are not only the representatives of the Fellows, and have not only responsibilities to the Fellows and Members, but the College holds an important relation with, and its Council have grave responsibilities to, the whole profession, the general public, and the State." Those words could not by any possibility be improved upon. How had its duties to the profession been discharged? He had never been one of those who had decried the management of the Colleges. As far as he had seen they had been anxious to do their duty; with respect to the examinations especially, their attention never flagged, and they had been anxious to make them, if possible, more practical in every way. At the same time, it could not be denied that the system of examinations which the College had instituted, and were now administering, was one which pressed hardly upon the student and upon the medical practitioner (cheers): on the student in that much of his time was absorbed in learning what he afterwards was compelled to forget (cheers), that a large period of his study was not given up to the practical study of disease (hear, hear), and that his toil was very frequently rewarded, however industrious he might have been, by frequent rejection and mortification at the last; and on the practitioners because they were mortified by the ill-success of their sons, and mulcted in pocket considerably by the amount of time which all this very frequently involved. (Hear, hear.) This was a matter which required the attention of the College. He did not think the Council could be altogether satisfied with it, but they had worked hard at the matter, and had done what they considered to be their best. He only regretted that the examinations appeared to have a tendency to become more and more complicated and less and less practical. (Cheers.) But when he turned to other matters connected with the profession, he could not congratulate the Colleges at all either on their success or on their endeavours. When they saw that medical men, trying to earn their livelihood by honest practice, and to whom quackery and cheating were odious, received from great institutions like that College and the College of Physicians no protection of any kind (loud cheers), they could not help thinking that a little more knowledge of, and sympathy with, the circumstances of the ordinary members of the profession would do a very great deal of good to the Council of that College; and one reason for asking that the Council would move the Crown to admit within their council-chamber some of the Members as distinguished from the Fellows was that it might be more in sympathy with the general body of the profession on matters of this kind. Then, turning to the duties that the College owed to the public, they had one matter for just pride, for in no part of the world were there such splendid monuments of the liberality of private individuals to the State and to the world as those contained within the College walls. The Hunterian Museum was a proud monument of what energy and liberality, continued over a series of generations, might do for the public and the profession. But leaving that, he was not aware what duties the College discharged to the public, and yet there were plenty of duties that it might discharge. (Hear, hear.) Was there, for instance, any public scandal, any public abuse, more gross than that of the hospitals of this country? Were there not, besides the great hospitals, which in themselves were not entirely free from abuses, a crowd of minor institutions which were really in no sense of the word public charities? (Hear, hear.) He believed that this matter was entirely a stranger to the deliberations of the Council, but it ought not to be. If the Council comprised members who knew more about these matters and suffered more by them, their action on this question would be very considerably stimulated; and for this, amongst other reasons, he should advocate the admission into the council-chamber of some of the Members. With regard to the duties which the College owed to the State, the State appeared to be considerably more content than he was at their neglect. He never observed while he was on the Council that the College was ever consulted on the subject of legislation, or that its opinion exercised more influence on the progress of legislation than that of far inferior bodies or of private individuals. He believed that the reason was because the College did not represent a large constituency (hear, hear); and if the Council were strengthened by having a great constituency anxious to connect themselves with it, he was quite sure that its influence upon the progress of legislation and on State questions would be infinitely extended. It was with a view of remedying these evils that he was anxious that the Council should take into mature consideration the admission of Members to a vote and seat in the Council. They were not foolish enough to suppose that any violent change ought to take place, but they were quite certain that it would give it immensely increased force with all the bodies to whom the report referred—viz., the profession, the public, and the State. The Council asked for a detailed plan, but the Fellows and Members were certainly not prepared to supply the details of the plan to persons who altogether repudiated the principle, and could only use the details for the purpose of obstructive criticism. At the same time, they were anxious to argue this matter as friends, and in the resolution had gone a little further than they need have done, for they had provided the heads of a scheme. In doing that he wished to correct an error that had appeared in the papers. They did not profess for a moment that these were the unanimous opinions of their two Associations. The Members were unanimous to a certain extent; they wished for more, but they were prepared to accept a representation on the Council in the proportion of one to four. But with respect to the admission of Members into the Council the Association of Fellows was not unanimous, for although the resolution was passed unanimously at the meeting of the Council of the Association the other day, that unanimity was only due to the fact that certain gentlemen who thought otherwise were absent. There was no doubt a minority of both Associations, who, though they would be perfectly willing to give the vote to Members, did not at present desire to see Members on the Council. It would be a matter of extreme interest to know in what way the opinion of the Fellows was divided on this subject, and he thought that that opinion could be much better obtained by the Council of the College than by any private association. The Council was pledged to obtain an alteration of its Charter in favour of Fellows who wished the privilege of voting by papers, but he should like to ask how they would meet a strenuous opposition on the part of Members who claimed similar privileges in their own College to those which had been conceded to them in the chief public body connected with the medical profession. (Cheers.) They were most anxious that these questions should not come before the public or public officials as matters of controversy, and that when the new Charter was applied for the whole body of the profession should say that they were satisfied with it. (Cheers.) But that could not be if there were really, as he believed there was, a determination on the part of the Members to have some voice in their own College, and if in spite of such an expression of determination the Council should still try to exclude them. (Cheers.)

Dr. DANFORD THOMAS said, on behalf of the Association of Members, he had much pleasure in seconding the resolution. Many of them were present last year when a similar resolution was carried by a large majority. This resolution, though modified in form, declared that the Members should take part in the election of the Council, and asserted as a principle that direct representation should follow. It was in accordance with the feelings of the Fellows, who in subcommittee and in the General Committee of their Association had agreed to support the Members in their just and natural aspirations to become more closely affiliated with the College of which they claimed to consider themselves an integ[illegible] They were Members not

merely because they paid a certain sum of money and received, as suggested by some, a *quid pro quo* in the shape of a diploma, but after four or five years of continuous study and the passing of the required examinations they had become legally entitled to the Membership, and the Council had no option in the matter. Was it, then, unnatural or to be wondered at that, as properly constituted members of a corporate body, they should expect to take some part in its government, in its proceedings, and in the election of its Council? Hitherto the Council had not seen its way to accede to these laudable desires on the part of the Members. It had suggested, however, that it would be willing to consider any well-devised scheme adopted by a majority of the Fellows and Members. The resolutions now submitted were the result of many meetings and of joint considerations by the Fellows and Members in the only practical manner at their disposal; and although the Members had conceded much, and had departed from their original standpoint, they had done so in deference to the wishes and suggestions of the Fellows, and in order that they might approach the Council in a spirit of unity and accord. (Cheers.) He hoped that ere long the Council would be prepared to hold out the right hand of fellowship, and would be ready to believe that in keeping touch with the Members and affiliating them more closely to itself the status of the College would be greatly improved and the hands of the Council materially strengthened. (Cheers.) For example, by the assistance of its Fellows and Members, and their collected accumulated knowledge, the annual report which they were that day invited to consider might be expanded by the Council, and become an authoritative record of the art and science of surgery and its progress in every quarter of the globe—a document of real and scientific value. Again, they must not forget that the acceptance of their resolutions might be the commencement of a movement in the direction of converting the College from what it was at one time—a trade guild—into a recognised seat and centre of surgical science and learning for the whole profession. (Cheers.) Medical graduates of universities—he spoke more particularly of the Scotch, which were great licensing bodies—had always had some share in the management of their institutions as members of Council, but they were now engaged in seeking a much larger and more efficient control than they had hitherto enjoyed, and so strong was the public feeling on this question—that their claims were practicable and reasonable—that a Bill submitted to Parliament last session was to be presented again as a Government measure in the spring of the ensuing year. (Hear, hear.) In conclusion, he reminded the Council that the great bulk of the College income had been derived from the contributions of the Members (hear, hear), and that whatever greatness of reputation the College had attained, it had been built up not merely by the labours of the Council, valuable as they undoubtedly had been, but by the general support accorded to it by its Fellows and Members throughout the world. Through them it had obtained most of its wealth and most of its dignity, and all of its position and importance. In return for this the Members asked nothing more than that which Parliament had in its wisdom accorded to the profession at large—viz., "direct representation." (Cheers.)

Mr. JOHN ERIC ERICHSEN said he had heard with very great pleasure the very eloquent though somewhat discursive address with which they had been favoured by Mr. Holmes, and also to the essay delivered by Dr. Danford Thomas; but he must confess that he had failed to be convinced by the arguments brought forward by either gentleman that it would be advisable for the Council to adopt the resolution that had been proposed. The only arguments adduced by Mr. Holmes appeared to be two—one that by the admission of Members into the Council there would be a better guarantee that the Council would exercise more influence than it had hitherto done in the suppression of quackery, and the second that by the introduction of Members into the Council and giving Members the franchise the weight of the College in all affairs of state would be increased. (Cheers.) That might be so or not, but he altogether doubted it. Dr. Thomas referred to the custom of the Scotch universities, but in the Scotch universities the graduates had no voice in the election of the governing body. Any franchise were given to graduates at those universities, it would not be to those who passed the minimum qualifying examination—the Bachelorship, for instance, [illegible] only to those who passed the fullest examination [illegible] mitted. If they were to be guided by custom, he might say that, so far as he knew, there was not a single collegiate or academic body in the country in which men who had merely passed the minimum qualification had the franchise for a seat upon the governing body. (A voice: "London University—how about the Convocation?") They had no seat upon the governing body—not upon the Senate. But this was not a matter on which they need appeal to custom, or on which there was any necessity for declamation; it was purely a matter of argument. He would ask, in the first place, did the Members of the College demand this as a right, or did they ask that it should be accorded as a matter of grace by the Council? ("As a right!") What right had the Members to ask it? A right must be founded on one of two bases: it must be either for the redress of a wrong, the restitution of some privilege that had been withdrawn or was unfairly witheld; or it must be in virtue of some inherent property in the Membership that gave that right. Had any privilege ever been withdrawn from the Members of that College? ("Yes.") They had never possessed the franchise. Before the institution of the Fellowship the Council was self-elected; it was practically elected by the Court of Examiners. In order to do away with that abuse, that great surgeon and very wise demonstrator, Sir Benjamin Brodie, instituted the Fellowship, with the view of widening the electoral basis, and giving the franchise into the hands of men who were *bond-fide* surgeons of repute and position. Since then, the franchise for a seat upon the Council had been in the hands of the Fellows; but the Members had no electoral power whatever—no right therefore had been withdrawn from them. With regard to the Membership possessing any inherent power by which they had, as it were, the right of the franchise, he would remind Members of a very eventful period in the history of each individual amongst them—that evening when they passed through the ordeal that enabled them to obtain the Membership, on which occasion an address was delivered to them by the President of the Court of Examiners. (Laughter.) That address probably went in at one ear and out of the other (laughter); it contained a definition of the privileges and immunities to be enjoyed by the possessors of that diploma, but not a single word was uttered which could lead them in any shape or way to expect that they would have the franchise of the College bestowed upon them. If, however, any Member desired the franchise and wished to get it, there was a ready means of doing so, and one of which many men who were engaged in practice availed themselves—namely, by taking the Fellowship. That door was open to every Member, and although there were only 1200 or 1300 Fellows, there was no reason why there should not be 12,000 or 13,000, if they chose to avail themselves of the privilege offered. If, however, they were to admit the Members on the same footing as the Fellows to the franchise, and to seats on the Council, what would happen? Many Members came up for the Fellowship not only on account of the scientific and professional distinction that it conferred, but also because it gave them the franchise, and because in their turn they had a right to count on a seat in the Council, and they might even aspire to the chair which their President so worthily filled. But if Members were admitted to all this, the Member who presented himself at that examination for the Fellowship and was rejected would nevertheless have exactly the same collegiate rights of franchise, and a seat upon the Council if he could obtain it, as his more successful competitor who passed creditably through the ordeal of examination. The whole thing would be an utter absurdity, and it would necessarily eventually lead to the extinction of the Fellowship. (No, no.) If this were not demanded as a right, and should be accorded as an act of grace, would it strengthen the Council of the College, or the College itself, in any way? What was the business of the College, and what were the functions of the Council? The business of the College was not political—they left that to an association; it was not ethical—they left that to the Medical Council; it was not commercial—they left that to anyone who chose to take it up. (Oh, oh!) The business of the College was twofold—it was educational and scientific. It was educational in this sense: it was the great examining body of the country, and through the medium of its examinations it controlled the education of the future surgeon. Who were the people who could do this most efficiently? They were certainly the men who had been the teachers in the medical schools throughout the country. Education was a business that had to be learnt, as well as other matters, and no man could be a thorough

examiner unless he had been a teacher for years. He would ask where did they find the teachers of those subjects with which alone the College concerned itself—anatomy, physiology, and surgery? They found them almost exclusively amongst the Fellows. With regard to the scientific aspect of affairs, which was the second great business of the College, the arrangement of its museum and its libraries and general scientific departments, he had no hesitation in saying that, with all respect to the great body of Members, they did not offer so good a body of scientific men as did the Fellows of the College. Therefore he did not see it was possible to strengthen the Council, so far as its scientific department was concerned, by the infusion of 25 per cent. of Members into that body. Take, for instance, the fellowship of the Royal Society as a measure of a certain amount of scientific status. They would find a very large number of Fellows of that Society upon the Council, and there would be no possibility of adding to the strength of a Council which comprised such men as Paget, Lister, Marshall, Hulke, and Johnson by the infusion of any number of Members outside. But if there were justice to be done to the Members in this matter, there was also some justice to be meted out to the Fellows. With regard to the Association of Fellows he knew nothing. He should like to know of how many Fellows it was composed, and what was its proportion to the great body of Fellows. This he might say, that, as far as the Fellows were concerned, they had a superior position derived from their superior professional and scientific status, gained by examination; gained by the evidence that they had given of superior knowledge and power of work or ability, whatever it might be; and they had, besides this, the position that was due to them in relation to the franchise and to the Council. If the number of Fellows upon the Council were diminished by one-fourth, they would *pro tanto* diminish the chance that every Fellow had of coming upon that Council; that would be simply robbing Peter to pay Paul. (Oh, oh!) They were taking something from the Fellows to give it to the Members. (Cries of "Time, time.") He must apologise for having detained the meeting so long, but it was a matter on which he felt very strongly, believing as he did that it would neither add to the dignity, the influence, or importance of the College in any way whatever to make any change in the present mode of election to the Council.

Mr. MARSHALL (Dover) said he had listened with great pleasure to the excellent speeches of the mover and seconder of the resolution, whose arguments entirely covered the subject. He would therefore appeal to the sense of justice, the good feeling, and the desire for conciliation, which he was sure must exist in the mind of every member of the Council. He hoped that the resolution would not only be passed by a large majority of the Members, but also by the wish and support of the Council. He was only speaking the feelings of the meeting when he said they would rather take it as a free gift from the Council than have it forced on by a majority. (Cheers.) He hoped the meeting would not be influenced by the speech just made by a gentleman whom they all honoured and venerated (cheers)—a gentleman of whom it was impossible to speak in too high terms. He was certainly surprised and grieved when he heard Mr. Erichsen make such a Conservative speech (laughter), when he remembered that not very long ago the same gentleman was the Liberal candidate for the University of Edinburgh. (Much laughter.)

Mr. ERICHSEN.—This is not a political body.

Mr. MARSHALL said he did not believe that such an anomalous state of things as the exclusion of the Members from participation in the government of the College could much longer exist. It might have been tolerated fifty or sixty years ago, but it could not be tolerated now. Whether the resolution was carried on the present occasion, or next month, or next year, it was only a question of time (Hear, hear), and on behalf of those who had initiated the movement he would declare that they intended to persevere until their efforts were crowned with success. (Cheers.)

Mr. RIVINGTON said it had been generally stated in influential quarters that the arguments adduced on the preceding occasion made a considerable impression on the usually impassive minds of the stationary element in the Council. That view was partly borne out by the very lengthened interval which had elapsed since the resolutions of the Fellows and Members were presented to the Council. He did not wish to strike any note of discord, but he thought that the reply had, after an interval of eleven months, been vouchsafed in a form which was scarcely polite to the Fellows and Members. This view was also borne out by the Fabian tactics which had been adopted, and also by the improved tone of the latest report. That report was bland and courteous, and was also in the highest degree encouraging, inasmuch as it contained in itself strong evidence of actual conversion (laughter), but unfortunately conversion or conviction was not always accompanied by a frank acknowledgment. The old proverb remained true that "a man convinced against his will was of the same opinion still." The Council actually invited the submission of a plan of representation of Members on the Council, and they promised faithfully to give to the plan the most careful consideration; but if they were not prepared to accept any such plan such an offer would be a mockery, and he could not believe that the Council would stoop to such an unworthy artifice. The only alternative to that interpretation was that the Council were in reality convinced of the political necessity of granting what the Members desired; but, being convinced against their will, they took care to affirm in the very forefront of the report that they were not convinced, as though they said, "We will do this obnoxious thing if sufficient pressure is brought to bear upon us." (Laughter.) Exclusive privileges were right and proper in certain cases when no injustice was done to others, and when policy and expediency were not opposed to their maintenance. The President and Members of the Council enjoyed the exclusive privileges of their office, but the exclusive privileges of a very small minority of a very large constituency were antagonistic to the spirit of the nineteenth century, and it was chimerical to hope to maintain them. The least satisfactory feature of the reply of the Council was the contrast presented between the jealous guardianship of every atom of political privilege, and the laxity in lowering or proposing to lower the academic status of the Fellowship by admitting Members at a comparatively early age, either with a modified examination or without any examination at all. It was, however, utterly futile to expect any solution of this question from any kind of proposition concerning the Fellowship. There were at present only 1124 Fellows, but if the number were increased to 3000 there would still be 15,000 Members who would go on demanding enfranchisement. He believed the Members would be satisfied with having four representatives on the Council, and it would not be necessary to take away one single representative of the Fellows. If the Council continued to say, in their highest and loftiest manner, "We are not convinced of the necessity of this change, but we will consider any plan submitted to us, and at the same time reserve to ourselves the right not only to modify details but also to reject the principle," then the Members of the College would be seriously wanting in ordinary acumen and business capacity if they receded one inch from the position they had already taken up. (Cheers.) He heartily agreed with the proposition that "it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education," if the Members of the College were empowered to take part separately in the election of the Council, and if they were eligible to sit in the Council, "provided that no Member of the College shall be entitled to vote till he have been such Member for a period of ten years." He would however, prefer that the number of years should be determined in the Committee which was to be appointed by the Council and the Associations to consider the question. (Laughter.) With regard to the proposal that no Member should be eligible to sit in the Council "till he have been such Member for a period of twenty years," he considered ten or fifteen years would be quite sufficient. Let the present constitution of the College continue pretty much as it was, but let the duration of councillors be reduced from eight to five years, and let a few Members' representatives be placed on the Council. He strongly objected to the Associations of Fellows and Members. They were necessary evils at the present time, but they were opposing the Council, and it was not desirable that such outside bodies should exist. They ought to be brought within the pale of the constitution. (Cheers.) The Members might be formed into an association called a Convocation, and the Convocation might meet annually, and every member of Convocation might have the right to vote in the election of members of Council. At the University of London any graduate was eligible to vote after he had been a graduate for two years. If the limit were placed at three years that would be a sufficient interval to find out [illegible] of, whether they

advertised or not. (Laughter.) The restriction of twenty years simply limited the area of choice. If the members of the Council were so exalted that they could not bear the idea of any Member of the College sitting betwixt the light and their nobility, it would be easy to make all representatives of Members sitting on the Council Fellows *ipso facto*. The exclusion of Members from all control over the affairs of the College, from all voice in the framing of educational regulations and regulations for examination, and from all control over the expenditure of money which they had themselves contributed towards the funds of the College, was essentially unjust. (Cheers.) It was unjust by reason of the numbers of the Members, by reason of their position in the College as actual Members of the Corporation, by reason of their social standing, and by reason of their liberal education. This exclusion could be remedied without doing harm to anyone, and also without infringing in any way on the present rights of the Fellows. The admission of Members to the Council would give a needed variety to the Council, and vary the monotonous type of the hospital surgeon. (Laughter.) Surely when the right of direct representation on the Medical Council had been given, it was anomalous that it should not be given on the Council of the College. The concession asked for was in accordance with the spirit of the age, which many of the leaders of the profession had failed to recognise. At present, the Council were blind, and could not read the signs of the times. The spirit of the age also loudly called for facilities for granting degrees for London students. The schools of London were languishing, almost decaying, and the tide of students was flowing rapidly northwards to the schools of the Scotch universities on account of the passive attitude of the University of London, which would not apply any effectual remedy. The same influence appeared to predominate at the Council of the University as at the Council of the College, only there was a very remarkable difference; for while at the University it was considered absolutely necessary to maintain the standard of education at the highest point, at the College it was actually proposed to confer the Fellowship without any examination in anatomy and physiology. (Laughter.) He believed that representatives of Members, when on the Council, would have the courage of their opinions. Fellows came forward and posed as great reformers and roared loudly as lions, but as soon as they reached the desired haven they cooed as gently as sucking-doves. (Laughter.) The representatives of Members would not be exposed to those influences which seemed to overcome the reforming feelings of the Fellows; they would not be candidates for seats on the Board of Examiners; they would have nothing to look for from their seat on the Council, and therefore they would not listen to the voice of the charmer, charmed he never so seductively or so well. A great question had sprung up in connexion with the Medical Act of 1886, in which the Members of the College were specially interested. He referred to the refusal to admit the Society of Apothecaries into any conjoint scheme in London. The result of such a refusal would be a second examining board in London. (Cries of "Time, time.")

The PRESIDENT said there was a distinct motion before the meeting, and he hoped that Mr. Rivington would confine his remarks to it.

Mr. RIVINGTON said a second examining board in London would be an intolerable evil. If representatives of the Members of the College were placed on the Council, they might be trusted to take just views of that and other important questions. (Cries of "Time, time.")

The PRESIDENT said he should really have to interpose with authority if Mr. Rivington did not pay attention to the appeals that were made to him. He had repeatedly wandered from the question before the meeting.

Mr. RIVINGTON said the representatives of the Members would exercise a vigilant supervision over the expenditure, and he did not believe they would endanger the existence of the College or run any risk of forfeiting the Charter by holding property in excess of the provisions of the Charter. There was also the question of the large expenditure on the Board of Examiners. (Renewed cries of "Time, time.") He considered that the only just principle to the appointment of examiners would be that every medical school should be represented upon the Council as examiners. There was one other point which he desired to refer to. (Prolonged cries of "Time, time.") The medical profession craved for unity. (A voice: "[illegible] laughter.) It did not seek divided authorities and internecine conflicts. The Council of the College alone stood in the way of the realisation of the wishes and aspirations of the Members.

The cries of "Time, time," "Sit down," "Vote," "Order, order," &c., continued for some minutes, during which Mr. Rivington repeatedly commenced a sentence, but was never permitted to finish it.

The PRESIDENT said that if Mr. Rivington did not accede to the appeals to finish his speech at once, he should put it to the meeting as a distinct question whether he should be further heard.

Mr. Rivington thereupon sat down.

Mr. R. PARAMORE attempted to continue the discussion, but the cries of "Vote, vote" were so vigorous that he found it impossible to proceed.

The resolution was then put and carried, with a very few dissentients.

Dr. RALPH GOODING proposed: "That, with a view to give effect to the recommendation in the foregoing resolution, the Council is hereby respectfully requested to empower certain members of its body to meet and confer with representatives of the Association of Fellows and of the Association of Members together, with, if necessary, an equal number of Fellows and Members who may not belong to either of the Associations, to be selected in any manner satisfactory to the Council." He said the resolution followed as a natural sequence to those sentiments which the meeting had just endorsed. Enough had already been said as to the many virtues, the intelligence, and the strong claims to direct representation possessed by those who had honourably gained the station of Membership of the College. He would, however, remind Mr. Erichsen that there was a distinct precedent for granting the privileges which had been so long denied. At the London University graduates of a certain standing were endowed with the highest privileges and the widest powers that the University could bestow. They were eligible as members of Convocation, and also for election to the Senate. Besides this, they could all record their vote for a representative in the Imperial Parliament. When he reminded the meeting that such names as James Paget, William Jenner, William Gull, George Burrows, George Johnson, Richard Quain, and Samuel Wilks were indelibly inscribed on the senatorial roll-call, he would ask his brother practitioners whether they considered that the trust reposed in those graduates had been in any way abused. No less than one-fourth of the members of the Council of the College were graduates of the London University, and would therefore endorse the observations he had made. The Council in the report fully recognised the gravity of the question, but complained that they had no detailed plan before them embodying the desired changes; but no such plan could ever be produced until some form of *rapprochement* were arrived at between the several parties concerned. He therefore hoped that his resolution would be agreed to, and if the governing body would carry out its principle, results would be produced largely conducive to the prosperity and future progress of the corporation. The Members did not crave for abstruse lectureships or dignified professorial chairs; they did not wish to diminish the privileges of the Fellows, or in any way to impair their *status;* on the contrary, they pledged themselves to resist any proposal which might in any way detract from the value of that distinction.

Mr. JOHN TWEEDY seconded the resolution. He said he sincerely felt that if the resolution were carried into effect great good would result to the College, and great honour and dignity to the profession. For many years it was his duty to be in close relationship with members of the Council, and he could conscientiously say that he believed every one of them was earnestly anxious to do what he considered best for the College; but they thought rather too much of the exclusive interests of the College, and not quite enough of the interests of the Fellows and Members. He was once on a deputation from the Association of Fellows to the Council, and he was gratified to find that some result had ensued. If a conference were held between the various sections of the Fellows, Members, and members of Council, an amicable understanding would soon be arrived at. There would be a ready adjustment of all differences, and from that time forward the College would go on with increasing prosperity. It was very important that these rudimentary questions of the constitution should be settled, so that other and more dignified matters might be grappled with, such as making the College not merely an examining body, but a great academy

for surgical research and the advance of surgical science. He hoped that the Council would see its way to receive the resolution in a friendly and amicable spirit. (Cheers.)

The resolution was then carried *nem. con.*

Dr. F. H. ALDERSON proposed: "That with reference to the report from Mr. John Marshall on page 15 of the Council's report, this meeting requests the Council of the College to consider the advisability of accepting an arrangement for combination with the Apothecaries' Society, as well as the College of Physicians, for the purposes of conjoint examinations for medical diplomas in England and Wales under the Medical Act of 1886, and to report thereon at a future meeting of Fellows and Members to be summoned for the purpose at an early date." He said that the resolution dealt with a matter affecting every member of the College, the general public, and perhaps the very dignity of the College itself. It was a question upon which full information should be obtained before a decision was arrived at. The Council had very few opportunities of knowing the wants of the Members, how they were influenced by irregular practice, and how much they suffered from it. When this question was dealt with by the College in July last, and when Mr. Marshall decided that it was not for the advancement of the College to admit the Apothecaries' Hall to the conjoint scheme, matters were very different. At that time the Hall merely gave an examination in medicine, they had no right to give any degree in surgery; but since then the scene had shifted, much to the advancement and improvement of the Apothecaries' Hall. The College should now take advantage of this, accept things as they are, and recognise that it was advisable to consider whether the Hall should be admitted to the Conjoint Scheme. At present no man had a right to call himself a surgeon unless he had a diploma of the College, but if the Apothecaries' Hall were made an independent board of examiners they would confer a diploma that would give the right to anyone having their licence to call himself a surgeon. That would be detrimental to the interests of the College and to the public interest, as it would introduce an inferior class of practitioners to compete with the Members, not only on equal terms, but perhaps on superior terms, for it was mooted that if the Hall were not permitted to enter into combination with the Colleges of Surgeons and Physicians they would look elsewhere, to a university—Durham, perhaps,—and make arrangements by which their licentiates could obtain a degree, and have a right to call themselves "Doctors." The College must therefore take care that no single corporation should confer what might be called an inferior qualification, or certainly at an inferior fee. If this were not seen to, the general public as well as the Members of the College would suffer. The Government had decided that the Apothecaries' Hall should not be crushed out, that any body examining in medicine and midwifery should also examine in surgery, and so be enabled to give a complete diploma. Since the Act was passed a change had come over medical politics, and what was desirable a few months ago might be far from desirable now. A man, and certainly a Council, had a right to go with the times; they might change their opinions, and no doubt they would give the Members an opportunity of becoming Fellows, which many of them, like himself, would appreciate. The alternative was to admit the Hall to the Conjoint Scheme, and then there would be one Examining Board in London, giving a thorough, complete, and full diploma. There was very great secrecy about the College of Physicians. He had never heard of meetings of their licentiates, such as there were at the College of Surgeons. The Council there appeared to sit in secret conclave, the licentiates knowing nothing about them; they were a very honourable and august body, but very secret, and for that reason the Hall should be admitted to the new scheme of medicine. No further opportunity might occur for fifty years. It was most important that the Council of the College of Surgeons should study the wishes of the Members, and proceed cautiously and deliberately to take this question into consideration.

Dr. BURGESS, in seconding the motion, said he was formerly an examiner at the Apothecaries' Hall, and knew something about the working of that institution, and the examination was as rigid and as good as any in the country. As regards the possibility of the Hall starting a separate examination, he thought they would do it, and, what was more, it would answer. He would strongly recommend the College not to burn their boats in too great a hurry, because they might want them to row back in when it was too late.

Dr. WICKHAM BARNES said he had had thirty-three years' experience in general practice, and knew a little of the requirements of the public and the feelings of a very large body of medical men; and, as the President's labours were directed to the interests of the public as well as to those of the patients, he felt that the expression of the opinion of the meeting would be gladly welcomed by the Council as a guide to their future deliberations. Everyone admitted the valuable services of the Society of Apothecaries, and therefore it should have the honour which was justly due to it. What would be regarded by the uninitiated as a slur should not be cast upon a highly respected body of men throughout the country who held the licences of the Society.

The resolution was carried *nem. con.*

Mr. WILLETT (in the absence of Mr. Paul Swain) moved: "That, in the opinion of this meeting, the method recommended by the Council for widening the basis upon which the Fellowship is obtained tends to lower the academic status of that diploma, and, in the interest of surgical education, is not advisable." He did so, he said, rather by way of protest. There were already three grades of Fellowship, and the Council had proposed three or four more. There was therefore great scope for discussion, but he would not prolong the meeting by any further remarks.

Mr. RICHARD DAVY seconded the motion.

Mr. W. STEEL moved as an amendment that before the word "method" the word "first" should be inserted, as some Members disapproved of the one, but could hardly say they disapproved of the other.

Mr. ASHTON ELLIS seconded the amendment, which was put to the meeting, when twenty-four hands were held up in its favour, and the same number against it.

Mr. STEEL said he thought the amendment had not been understood.

The PRESIDENT thereupon again put it, when it was supported by 38 to 34, and subsequently carried as a substantive motion by 48 against a very few.

A vote of thanks to the President concluded the proceedings.

IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.

THE autumn meeting of the above Association (which now includes 423 members) was held at 49, Berners-street, London, on Thursday, the 4th inst., the President, Dr. H. Macnaughton Jones, F.R.C.S.I., in the chair. The members and their friends, to the number of fifty-five, dined together the same evening at the Café Royal, Regent-street, the President in the chair. Among the guests present were W. Howard Russell, Esq., LL.D., Dr. Withers Moore, Professor Michael Foster, and several colonial physicians, including Drs. J. T. Chapman and G. A. Syme. Among the members present were Sir Thomas Crawford, K.C.B. (President-elect of the Association); Professor Gerald Yeo (Chairman of the Council); Professor Alex. Macalister, F.R.S. (Cambridge); Inspector-General J. N. Dick, R.N.; Deputy Inspector-General W. H. Lloyd, R.N; Deputy Surgeon-General N. Ffolliott; Brigade-Surgeon G. C. Gribbon,; Surgeon-Major E. A. H. Roe; and Dr. J. Stewart (Hon. Secretary).

After the usual loyal and patriotic toasts had been duly honoured and responded to severally by Dr. W. Howard Russell, Professor Michael Foster, Professor Gerald Yeo, Sir Thomas Crawford, and Dr. Dick, Dr. Withers Moore proposed the toast of the evening, "Success to the Irish Medical Schools and Graduates' Association," coupling therewith the name of the President. In reply, Dr. Jones spoke of the rapid growth of the Association, opining that their present number, though large, could only be considered the nucleus of future greatness. The toast of "The Irish Medical Schools" was proposed by Professor Alexander Macalister. Dr. Dolan, of Halifax, who had been adopted as one of the candidates recommended by the Association for "Direct Representation," replied, and a most agreeable evening closed with music and recitations by the members.

ON the 3rd ult. a meeting was held at Chester to consider the desirability of presenting a testimonial to Dr. Waters, of that city. It was decided that the presentation should take the form of a portrait of the recipient, and subscriptions [illegible] purpose

THE LANCET.

LONDON: SATURDAY, NOVEMBER 13, 1886.

ONE of the most obvious results of the general meetings at the College of Surgeons, now becoming an annual custom, is the improved tone in which the discussions are carried on. When we look back to the indecorous conduct which characterised one or two of the earlier meetings, the absence of any concerted plan of action, and the quality of the speakers, we are struck with the great improvement which has been made in all these respects, and congratulate the Fellows and Members most heartily. We can only hope that they will continue their deliberations in the same spirit of moderation, notwithstanding the little sympathy they meet with at head-quarters. Yet, notwithstanding this apparent want of sympathy, there is abundant evidence in the reports which the Council presented to them at the meeting that some of their representations are being acted upon. And, as Mr. HOLMES happily pointed out, the President himself (Mr. SAVORY) is holding office during two consecutive years, thus breaking away from the tradition and custom of handing the presidency round the council-table. We agree with Mr. HOLMES in thinking that the dignity of the office will be enhanced, and that this change from routine will be favourable to the efficiency of the College. Further evidence of conciliation is to be found in the statement of the Council that they are quite prepared to give careful attention to any jointly-authorised plan by means of which a share of representation in or upon the Council may be given to the Members of the College. It is significant, too, that among the members of Council who supported the President at the general meeting last week was a well-known and highly-esteemed general practitioner, the first who has been avowedly elected as such.

Most important of all, however, is the absence of any organised opposition to the proposals for reform which were presented as the joint recommendations of the Associations of Fellows and of Members. Nor is this all; there is no real personal opposition. At the meeting in 1885 the only spokesman in favour of the *status quo* was Mr. BRUDENELL CARTER, while at this year's meeting Mr. ERICHSEN stood alone as champion of the Council. We do not know whether these gentlemen spoke on behalf of the Council, but whether or no, neither of them adduced a single argument which will hold water. Mr. ERICHSEN'S contention was weak and illogical, and his arguments against the desired reforms were still further weakened by the known liberality of his political views, as recently enunciated in Edinburgh. Moreover, Mr. ERICHSEN has hitherto been regarded, and has always acted, as a bold but careful reformer. We were therefore quite unprepared for such a conservative speech, and still more for such an illogical one as that made by Mr. ERICHSEN at the College of Surgeons. His argument that there is not a single collegiate or academ[illegible]hich men who had merely passed the minimum qualifying examination had the franchise or a seat upon the governing body was met by a direct negative, for it was stated that *every* graduate at the University of London of two years' standing was eligible to vote and even to sit on the Senate if his fellow-graduates chose to elect him thereto. When Mr. ERICHSEN inquired whether the Members demanded these changes "as a right or as a matter of grace," the meeting loudly proclaimed "As a right." He then said, "A right must originate either in the redress of a wrong, the restitution of a privilege withdrawn or unfairly withheld, or it must be in virtue of their most inherent property in the Membership." Strangely enough, it is not on *one* but on *all* these grounds that Members now seek for the full franchise, and these are just the grounds on which they claim it. Mr. ERICHSEN, as a past president of the College, must know very well that formerly Members of the College were eligible for the Council and for the highest offices, and that they were deprived of these privileges by the institution of the Fellowship. The wholesale election in 1843 of some 250 of the Members to the Fellowship silenced opposition for the moment, and though it gave great offence to the Members at large, matters were allowed to remain as they were. As to whether Membership of the College ever implied an inherent right to the franchise, we would ask, "What is 'the fundamental principle of *corporation*,' and why was the term Member selected in preference to Licentiate?"

Nor was Mr. ERICHSEN more happy or more logical in supporting the Council in their refusal to grant the wished-for changes "as an act of grace." He questioned whether such a step, "as an act of grace," would strengthen the Council or the College in any way. The business of the College, he said, was not political; it was not ethical; it was not commercial; but was educational and scientific; and he contended that the men who could most efficiently control education and examinations were those who had been teachers. Surely such an argument is radically unsound, unless the chief object of the Council is to make teachers. But surgeons have other purposes to serve: they have to watch over the health of the State, and education and examinations alike must be made to subserve this great purpose. It cannot be doubted that the Council of the College will be strengthened, in the best sense of the word, by the admission of men practically acquainted with the needs of the State, and with the requirements, as to education and general attainments, of those who go forth as general practitioners. As a politician Mr. ERICHSEN will look at all these matters from that standpoint, and will not be surprised that we have ventured to criticise him somewhat freely.

Mr. HOLMES' speech in favour of the advocated reforms was a model of careful reasoning; when it has been circulated and carefully studied, it cannot fail to exercise considerable influence upon any waverers that may exist among the Fellows. Mr. HOLMES speaks with the authority of a Fellow and a past member of Council, and when he urges that it will tend to promote the interests of medical polity and education if Members are empowered, under certain circumstances, to take part in College management, we may feel quite sure that

success will soon crown the efforts they are making to acquire this privilege. As his arguments will be found fully reported elsewhere, and as we have so often previously placed similar ones before our readers, nothing further need be said beyond an expression of thanks to this gentleman for his powerful advocacy.

Mr. RIVINGTON (to whose letter published in another column we would direct attention), we cannot help thinking marred an otherwise powerful speech, also in favour of reform, by the introduction of irrelevant matter and a little too much cynicism; and able as were the arguments they lost force by reason of their great length, for "brevity is the soul of wit." We differ from Mr. RIVINGTON on the question of the standing necessary to qualify for a vote and a seat in the Council, and think the Associations have done well in fixing the respective limits at ten and twenty years. A man can get the Membership of the College at twenty-one years, and could thus vote at thirty-one years, and sit in the Council at forty-one years of age. Considering the importance of the business of the College, it is well that a Member should have attained years of discretion before he is allowed to exercise his voting privilege, and still more before he is considered eligible to sit on the Council. The intervals will afford him leisure to work up the past history of his College, and to make himself thoroughly acquainted with the questions to be decided.

A resolution was also submitted and carried, praying the Council to empower certain members of their body to meet and confer with representatives of the two Associations and with an equal number of independent Fellows and Members to be selected by the Council. Such a conference will in all probability take place, for after their expressed readiness to consider any detailed plan duly authorised by the two bodies, the Council will hardly refuse such a natural mode of arriving at a solution of the questions in dispute. Mr. HOLMES expressed a hope that the Council might see their way to obtaining a distinct vote of the Fellows; it would be little trouble or expense to the Council, with all the machinery they possess, but a great expense and trouble to any private association. Moreover the result would be more official, and therefore more authoritative.

We last week referred to the future of the Society of Apothecaries, another subject that was touched on at the general meeting. The failure to secure the much-needed one qualification for England is standing proof of the small political influence which even the united Colleges possess. This is due largely to the want of constituents ready to help them when help is needed. It is to be hoped that the Council of the College of Surgeons will no longer resist the reasonable demands of its Fellows and Members, but will, on the contrary, take up and direct a movement which otherwise will assuredly prove too strong for opposition.

So uniformly has the analytical method been adopted, and so persistently has that line of investigation been pursued by the workers in almost every branch of science during the last half century, that it is quite refreshing to find a writer who has the spirit—we had almost said the originality—to employ, or even to drift into using, the synthetical method in the discussion of any subject in science. This fact alone would give a peculiar interest to the paper by Mr. FINCKS in the current number of the *Contemporary Review* on "The Gastronomic Value of Odours." It is the author's opinion that instead of multiplying the varieties of function, such as those of taste and smell, and separating these from what is called a general sensation, we may with advantage regard the differences which are now recognised as susceptible of being explained in a way to simplify the study of sensation, and with certain practical consequences and results. We are not, indeed, sure that Mr. FINCKS is himself aware of the value of the line of reasoning he has adopted, for synthesis may be the very last object at which his effort is aimed. Thus we find him saying: "The pungent quality of mustard, the fiery quality of alcohol and ginger, and the cool sensation in the mouth after eating peppermint, are due to the nerves of touch and temperature, which are commonly classed as one sense, though they are quite as distinct sensations as sight and hearing, or taste and smell." Nevertheless, he *is* synthetical, for he proceeds to argue: "So distinct are they that, whereas it is probable that the sense of sight is a modification or development from the sense of temperature, being an adaptation to faster ether waves; the sense of touch, whose function is the perception of solids, gave rise in successive degrees of refinement to hearing, for the perception of air-waves; to taste for the discernment of liquid qualities; and to smell for gaseous qualities." Presuming it must be supposed that by "liquid qualities" and "gaseous qualities" Mr. FINCKS means the qualities of liquids and gases respectively, it is easy to see that by following out the line of argument suggested, either intentionally or unwittingly, the reader, after losing himself in a maze of devious sense paths, is led back to first principles, and finds that in the excursion he has become convinced that the so-called senses are only so many means of bringing the organic consciousness to bear on the physical environment, and that the divers apparatus employed for this purpose are really modifications of one fundamental instrument by which the special qualities of bodies are enabled to impress the nerve centres within us. Sifted down to their ultimate elements—if we may so express our idea—the impressions thus produced or elicited or received are no more than positive, negative, or comparative records of vibration, either communicated by intermediate ether waves or directly by what we call contact, although, strictly speaking, there is no such thing as actual contact throughout the physical environment. Practically, it amounts to this: sensation is a process which may be illustrated by the action of the phonograph, which records every vibration into which its drum is thrown. The difference between sound and sight is simply the difference between one set of vibrations and another. The difference between heat and cold is the difference between vibration so rapid as to produce at one stage boiling, at another vaporisation, and vibration so slow as to cause, first, partial "congelation," and then actual freezing, with assumption of the solid form, with what we term rigid molecules, probably the erroneous conception of an incomplete idea. It is easy to see how this hypothesis of the unity of the several impressions, so far as th[illegible] concerned, must broaden

out into a theory which will cover the whole system of the special senses, and include every variety of sensation produced.

The main purpose of Mr. FINCK'S paper is to claim for the sense of smell that it constitutes the major part of the sense of taste, and that, in point of fact, we appreciate odours when we think we are tasting. There is much to be said for this view, and we incline to the opinion that the author will carry most intelligent readers with him. The paper may be studied with interest for its own sake, but it is rather for the sake of the principles involved in the argument than for the special doctrine taught in this paper that we dwell on it. The gossiping remarks about the effect of odours in eliciting or stimulating appetite are interesting in themselves, but they are also valuable as suggesting the consideration that one so-called sense may be excited by, and through, another. It is true that the odour of a well-cooked dinner elicits a desire to taste it; but it is not less true that the sight of it does the same, and if the sense of smell is essential to taste, so also is the sense of sight essential. Although the blind develop touch and some other of the perceptive faculties to a degree of acuteness which in some measure compensates for their want of sight, in the absence of this compensation, as in cases of sudden blindness, when there is not time for the special development of other senses, the sense of taste, and often that of smell also, will be found impaired. A familiar experiment that of attempting to discriminate between the flavour of different sorts of wine with the eyes blindfolded, or to determine whether a pipe or a cigar which the person blindfolded is smoking remains alight, will suffice to illustrate the very close connexion which subsists between sight and the other senses. Each and all are intimately related, and we doubt whether the connexion between any two of these special functions is actually closer than that which subsists between the whole number. In short, we incline to the opinion that Mr. FINCKS has simply expounded the truth with regard to the mutual helpfulness and interdependence of two of the senses while contending that smell is the complement, or a component part, of taste. If he will pursue his investigations a little further, he will find that all five or six of the so-called senses may be shown to be closely connected as faculties of perception, and this is simply and solely due to the fact that they are only special adaptations of the initial function of cognisance, which makes every variety of living organism struggle to bring itself into relation with the outer world by the development of special organs of perception according to its particular needs.

A SUBJECT of much importance as affecting the welfare of the sick poor, has been brought before the guardians of the Whitechapel Union by their clerk, Mr. W. VALLANCE. In a very thoughtful memorandum which he has prepared for their consideration, he discusses the possibility of improving the present form of medical administration of the Baker's-row Infirmary, and points out the difficulties attendant upon, and the advantages which would accrue from, a modification of existing arrangements. This question is not of mere local significance.

It will be recoll[illegible] LANCET Commission, the sick poor were removed from the workhouses and placed together in separate institutions, where better opportunity was given for their proper care and treatment. The chief officer in these infirmaries is the medical superintendent, who is aided in the performance of his duties by one or more assistant medical officers; these duties include not only the medical treatment of the patients, but also a considerable share in the administration of the institution. A large number of patients are persons suffering from chronic disease, together with others whose more temporary illness has compelled them to seek the aid of the State organisation which exists for the relief of the poor. The medical superintendent has thus to possess not only the knowledge of the physician, but has often to exercise the skill of the surgeon; it is true that purely surgical cases requiring operative assistance are willingly received into general hospitals, and in many cases the guardians encourage, and even pay for, their admission into these institutions; nevertheless, many surgical cases find their way into Poor-law infirmaries, and are solely dependent upon the medical superintendent for their chances of recovery. There is no doubt that the guardians and the poor have been well served, and that these offices are held by men who have amply justified the action of those who originated the scheme for the better treatment of the poor.

It has, however, been felt that a still better arrangement was possible; that by the appointment of visiting physicians and surgeons great professional advantages would result. The ailments of the patients would afford valuable material for study, the students who would accompany the visiting staff would derive benefit from the experience they would thus gain, whilst, to use Mr. VALLANCE'S own words, "there would be an improved classification of the sick, a better record of cases, a higher standard of nursing, and increased means for the efficient training of pupil nurses." There is no question that these gains would follow the appointment of a competent visiting staff to Poor-law infirmaries. CHARCOT has already taught that much information is to be obtained from the study of chronic nervous diseases that are to be found in somewhat similar institutions of his own country; and there is in England an almost unlimited field for investigation of other chronic maladies for those who have the knowledge and patience to undertake it. The main difficulty which stands in the way of any change which would give opportunity for this work to be undertaken is the question of administration. Mr. VALLANCE assumes that the adoption of the proposed scheme would, among other alterations, necessitate the transfer of the control of the internal administration from the medical officer to the matron. With this opinion we are not in accord. It has in some general hospitals been found to work well for the medical officer to retain complete control over all questions of administration, and at the same time to recognise the visiting staff as those who should decide upon matters of treatment in any case in which they may think it desirable. They would be to him in the same position as are the guardians in all questions of administration. Nor would the governing body cease to maintain complete supremacy over all matters involving expenditure, but they would, where this related to medical treatment,

have the additional advantage of the best professional advice.

Probably the best method would be that which would affiliate each of the workhouse infirmaries with one of the general hospitals possessing in connexion with it a medical school. Such an arrangement would be beneficial alike to the patients, to the guardians, and to the profession. Every additional means for the promotion of medical knowledge is an advantage to the whole community, and no other plan would bring to the service of the institution so much available experience and skill, or lead to the better utilisation of the material for study which it contains. But perhaps the greatest good which would result has not been fully seen. We have learned by degrees that the more general interest that is taken in public institutions and the more clearly every detail of their inner life is known, the more thorough is their administration, and the more substantial is the justice done between those who participate in their benefits and those who contribute to their maintenance. Such a result would not be the least of the good that would arise from the adoption by the metropolitan Poor-law authorities of the change indicated in Mr. VALLANCE'S memorandum.

ON or before the 15th inst. all registered practitioners will, or ought to, have received voting papers for the election of Direct Representatives on the General Medical Council, and these papers must be returned to the Registrars of the several Branch Councils on or before November 22nd. The time for action has therefore arrived. For many years the principle of direct representation of the profession on the Council has been discussed and agitated for, and it has been embodied in the recently enacted measure only as the outcome of persistent effort and unflinching pressure on the part of those who have been impressed with the need for bringing the Medical Council into more complete sympathy with the profession in general. The prolonged discussion has shown that even in the ranks of the profession itself and among its leaders there are those who oppose this direct representation, and to this fact in some measure it may be due that it has been adopted tentatively, and that only a very small proportion of the Council is to be thus chosen. Friends and foes alike are looking to this election with keen interest. How will the profession respond to the trust imposed in it? Will it show itself to be eager for the franchise, and possessed of an intelligent perception of its needs and interests? Or will it be indifferent to its newly acquired privilege, and leave the power it gives to be used by a few only, who shall wield it under the influence of personal feeling, rather than with a grave sense of responsibility? The answers to these questions will soon be given, and upon them depends in no small degree the future welfare of the profession. We have long contended for the right of direct representation, and have maintained against all opposition that the profession would use it worthily and well. The proof of this must now be given. This election will be important more as an indication of the spirit with which the profession views this great question, than as an indication of its preference for individuals. We would therefore urge all our readers, and all whom they may be able to influence, to see to it that a fitting response is made to the trust imposed on them. Let there be no delay, no indifference. But let every man at once fill up and sign his voting paper, and return it as promptly as possible. By a very large poll the profession will show that it has been in earnest in contending for direct representation, and that it does not look upon the opportunity of having a voice at the Council board as it never has been heard before as a matter of little moment. Our first motto should be "Vote early—vote all."

There is, however, another reason why *all* should vote. By so doing the profession will keep the election in *its own hands*, and will take it away from parties, cliques, caucuses, and wire-pullers. Should only a small proportion of voters exercise their right, it will of course be in the power of such men as we have indicated to rule the election, and in place of the voice of the profession being heard at the Council we may have the voice of a party or a clique. Let the profession demonstrate not only its desire and fitness for this franchise but its personal independence. The choice of members of the Council should be governed exclusively by considerations of their fitness for this special office. High professional status, former services to the profession, personal friendship, local connexion, and other similar considerations, should not of themselves influence the vote, but only such personal characteristics, habits of mind, and experience as fit a man to represent at the Council table the views, the aspirations, and the needs of the great body of the profession, who have hitherto been entirely unrepresented and very often misrepresented. We have already expressed the opinion that only those who have had long and daily experience in the labours of general practice can fairly represent the thousands of those who are devoting their lives to this honourable calling. And we are glad to see that this view is generally shared, for all the candidates are at special pains to show that they possess this first claim to the confidence and votes of the electors. Nor should assent to one or two "test" questions be allowed to have too much weight. No doubt it is important that the views of the profession on particular questions should be represented, but parliamentary and other elections demonstrate only too conclusively how unwise it is to make a ready assent to party shibboleths the high road to election. The personal and professional character of a man is of far more value than adhesion to one or two "cries" or "schemes."

Annotations.

"Ne quid nimis."

THE MEDICAL COUNCIL AND THE ELECTION.

IT seems a most unfortunate arrangement that, when all the energy of the staff of the office of the Medical Council is taxed to the utmost with the heavy work incidental to the election of direct representatives, the Medical Council should be about to meet to distract all concerned with other questions of difficulty and requiring undivided attention. Have our readers ever realised the amount of work involved in obtaining the accurate addresses of some 18,000 registered persons; then of sending to them voting papers without mistake somewhere between the 10th and 15th inst.—five days, be it noted, in which the officials must be preparing for the meeting of [redacted] then of receiving

and taking care of them for a period of seven days, up to the 22nd, after which no more can be received? Then will come the most serious work of all—the counting of the votes—which the profession will expect to be done with equal care and promptitude. Two days ought to be ample time to count the votes that will be received if the requisite staff of officials is at hand. The President of the Council is a merciful man. Has he really sufficiently considered the reasons for postponing the meeting of the Council in order that this laborious and responsible work of the profession and of the Council may be well done? We have said nothing about the question of scrutineers, having unbounded confidence in the fairness and judgment of the Medical Council. But it is right to ask that the question should be seriously considered by the Branch Council in view of the possibly jaded condition of officials; nor should the Council be above taking a hint from political authorities as to taking necessary securities in the matter. How many of the profession will vote? Nobody can say, and there is the greatest variation in the estimate. We advise all our readers to record and promptly return their votes according to their own judgment. A small vote would be condemnatory of the principle of direct representation. Moreover, let not voters be persuaded to indulge in mere personal preferences, as if voting were an act of private friendship, or as if giving one vote would exhaust a voter's duty. Three candidates have to be elected, and three votes should be given.

CLINICAL TEACHING IN THE UNIVERSITY OF GLASGOW.

THE Medical School of Glasgow is greatly exercised by a question raised and kept alive by Dr. McVail, in reference to the unhappy divorce between the splendid clinical resources of the Royal Infirmary and the teaching of the Glasgow University. This divorce is nothing less than a misfortune; unhappily it is one to which there are too many parallels in the profession. If the buildings and laboratories and apparatus of the Scotch universities could be brought to the London hospitals, what a perfect medical school we should have. If the Royal Infirmary of Glasgow, with its 530 beds, could be transferred to Edinburgh, what a lack it would supply, giving abundant material for dresserships, clerkships, surgical examinations and the like, which is not forthcoming now in any amount proportionate to the numbers of the school. This disproportion, indeed, is the principal defect of the Scotch universities, which the recent inquiry of the visitors of the General Medical Council disclosed. It is, however, a great one, and tells very seriously on the interests of medical students. It is an open secret that good Scotch students fare hardly at the examinations of the Royal College of Surgeons; and the explanation given is that they do not receive adequate clinical instruction. In the report of the visitors of Glasgow, strange to say, the same defect was noticed, in spite of a population of near half a million and a Royal Infirmary of over 500 beds, famous and classical as is the place where Sir Joseph Lister first enunciated and tried his antiseptic principles, which have so raised and revolutionised surgery. In the report, the visitors say the printed regulations of the Glasgow University are silent as to requiring candidates to have acted as dressers, clinical clerks, and obstetricians, nor could the visitors learn that any such requirements exist. Nor was the defence of the Medical Faculty to this objection convincing. Dr. McVail, in the Glasgow University Council proposed a bold remedy for this defect in the Glasgow University—viz., that the Royal Infirmary School should be incorporated into a college of the University, and all its teachers be placed on the same footing as University professors. We can easily see that the University would have much to say before accepting so bold [illegible] But the force of many of Dr. McVail's arguments cannot be questioned, and it would add immensely to the strength of the University of Glasgow as a medical school to associate it with the 530 beds of the Royal Infirmary.

PRIVATE BILL LEGISLATION AND SANITARY AUTHORITIES.

AN important judgment was delivered this week in the Queen's Bench Division by Mr. Justice Stephen with regard to the right of a sanitary authority to utilise the public rates in order to go to Parliament for an Act to perform such a duty as the provision of a proper water-supply. The action was that of Cleverton *v.* St. Germans Rural Sanitary Authority, the plaintiff being the solicitor to the defendants, who had unsuccessfully promoted a Bill in Parliament to interfere with certain water rights of the Earl of St. Germans, their object being to comply with an instruction of the Local Government Board in giving a proper supply of water to the parish of Torpoint, where there had been an outbreak of fever. On behalf of the plaintiff it was contended that a public body could go to Parliament for an Act for the performance of its legal duties; whereas, on the other hand, it was alleged on behalf of the defendants that Parliamentary action had only been allowed as within the power of a local authority where it was taken in defence of the rights and governing powers of such authority, and that apart from this an authority could only perform its duty by means of the powers then in existence, which in this case would have included action by means of a provisional order. Mr. Justice Stephen pointed out that Sections 51 to 70 of the Public Health Act indicated the methods by which a local authority were to supply water, and he held that the provisions of the Act, aiming, amongst other things, at the exercise by the central authority of a proper controlling power as to expenses &c. over local authorities, strongly pointed out that the way to a private Act was by provisional order, and that nothing in the Amendment (1878) of the Public Health Act pointed in a contrary direction. The principle was laid down over and over again that a public body was not to go for an Act of Parliament except in self-defence. Whether those who had employed the plaintiff were personally responsible or not for the expenses incurred Mr. Justice Stephen did not say, but he held that the authority had not the power to incur the expense, and hence judgment would be for the defendants.

THE MULTIPLICATION OF MICRO-ORGANISMS.

DR. PERCY FRANKLAND has made some interesting experiments upon the multiplication of micro-organisms (Proceed. Roy. Soc., No. 245, 1886), which have a distinct bearing upon the dissemination of infective disease. The procedure consisted in determining the number of colonies on a gelatine plate derived from one cubic centimetre of the water or other liquid containing the micro-organisms. He first selected a series of experiments upon natural waters, taking those supplied by the metropolitan companies. He found that at the ordinary temperature of the air there is a decided tendency for the micro-organisms to become reduced in number after storing for some time, but that the number of colonies is enormously increased by exposing them to an incubating temperature, just as happens to a less extent during the first few days of storage at ordinary temperatures. Differences in these respects were noted in accordance with the kind of water examined. Thus the micro-organisms in filtered river water become multiplied at 20° C. with far greater rapidity than those in the unfiltered waters, whilst the organisms in deep well-water have little tendency to multiply in the cold, but their multiplication at 20° C. is far in excess of anything

observed in the case of the river waters. Upon this Dr. Frankland remarks: "These tables show the enormous capacity for multiplication which is possessed by the micro-organisms present in this deep well-water. This is the more surprising, at first sight, when it is borne in mind that this water contains the merest trace of organic matter. It must, however, be remembered that this water is at the outset almost wholly free from micro-organisms, and that it has never before been inhabited by such living matters; it is only reasonable to infer, therefore, that those of its ingredients which are capable of nourishing the particular micro-organisms which flourish in it are wholly untouched, whilst in the case of the river waters the most available food-supply must have been largely exploited by the generations of micro-organisms which have inhabited them." In reading this, the mind involuntarily reverts to cases of epidemic disease spread through infection of wells, of which so striking an instance occurred at Caterham some years ago, when the dejecta of one typhoid patient were the occasion of a severe epidemic, due to the well which had been infected by them; and the cholera epidemic of 1849 is another out of an innumerable number of instances which, on the germ theory, can well be explained when one recognises the enormously rapid rate of multiplication of micro-organisms in favourable conditions. Dr. Frankland further describes his investigations as to the multiplication of pathogenic micro-organisms, testing for this purpose the bacillus pyocyaneus, Finkler-Prior's comma spirillum, and Koch's comma spirillum, for which, however, reference should be made to the paper itself, as the facts are too varied to admit of abstract, and require study, together with the tables which illustrate them. Suffice it that in water the Finkler spirillum rapidly loses its vitality, far more rapidly than either Koch's spirillum or the bacillus pyocyaneus. It is, however, pointed out that regard should be had to the original source of these micro-organisms before estimating the value of such investigations. There may be an inherent lack of vitality which would render conclusions drawn from one specimen quite fallacious.

METROPOLITAN ASYLUMS BOARD.

At a meeting of the Metropolitan Asylums Board, held on Nov. 8th, the Managers adopted a report of their General Purposes Committee recommending that their fever and small-pox hospitals should be made available for clinical instruction, and that the suggestion of the Local Government Board should be enforced: that gentlemen should be engaged as clinical assistants at these institutions; that they should be registered medical men, should have specified duties, and should in all respects be subject to the regulations in force with regard to the hospitals; further, that they should act as clinical assistants, that they should be associated with each hospital, and that they should have board and residence while engaged upon these duties. We regard with much satisfaction this extension of the usefulness of these institutions. It has always been a source of regret that so much valuable material should be lost to those who are desirous of gaining an intimate knowledge of acute infectious disease. Diseases such as those received into the Managers' asylums are not as a rule admitted into general hospitals, and as a result many men now leave their schools without having all the information they should possess of maladies of this kind. The action of the Managers will to a great extent overcome this difficulty; the effect of their decision upon the institutions under their charge is certain to be beneficial, the patients will themselves derive advantage from the more thorough clinical records of their cases which will be kept, and the medical superintendents will be relieved of a duty which, if thoroughly carried out, would make a serious demand upon their time, and will now be able to devote themselves more fully to the other responsible duties which devolve upon them. We have referred in another place to the hope that has been created that other Poor-law institutions will be made available for adding to the knowledge of disease. The question may well be considered hereafter, whether a closer relation between the medical schools and these asylums may not prove advantageous to the public and to the profession alike.

SOMNAMBULISM.

The habit of sleep-walking can often be so far controlled that no very serious consequences result. Unfortunately, as we are taught by a recent fatal case, the absence of such control may be attended by risks of no mean kind. The obscure physical change which underlies the state of somnambulism is, therefore, one which possesses a practical importance as well as a scientific interest for the physician. Its clear explanation, indeed, is as yet hardly possible, for like almost every functional nervous disorder, it might be explained on more than one hypothesis of perverted nervous action; and there is no theory of its pathological plan which does not vary of necessity with the shifting creed which at present embodies and expands with our ever-growing knowledge of brain function. The one point of which we can lay hold is the fact of co-ordinate motor activity, cerebral in its development, and surviving actively in a state of apparent mental rest. That this should be due to an autogenetic energy of motor centres, rather than to the influence of sensory impressions on these, is, however, hard to believe. The fact that sleep-walking is not necessarily associated with signs of muscular irritability during the intervals of wakefulness, while, on the other hand, such signs are common as proofs of constitution or disease—for example, chorea,—which have no definite connexion with somnambulism, must tend to confirm an opposite view. It is much more probable that a directing impulse of sensory origin is primarily accountable for this inconvenient habit. The cerebral sensorium is a large and undefined area—how far intelligent we cannot say. It is important, however, to remember that complex and once volitional actions carried on by its means do often become by practice so really automatic that partial sleep or stupor does not arrest their unconscious performance. This is what happens in somnambulism. The intellect and the controlling will are torpid if they do not slumber, while the sensori-motor man whom they should govern is awake and active. But whence comes the guiding impulse for his irrational movements? The sensation of muscular activity may supply much of this when the walker is on his feet. It is not so clear by any means, but highly improbable, that this force alone can begin his progression. We are therefore driven to look for other causes of cerebral stimulation, and in this connexion it will be instructive to turn aside and consider other conditions of a like kind. Take, for example, dreams. Here we have another state of half sleep, without, it may be, any tendency to rise up or walk, but with marked disturbance of the ideational faculties. The intelligent sensorium is then alone active, and that drowsily. A feature very frequently noticed, however, in dreamers is the tendency to restless movement. In such cases it would seem as if the capricious energy of scattered thinking centres touched here and there the springs of motor power and stirred them up to a like fitful action. May we not believe that there are other states of dreaming, with fancies perhaps less vivid and irregular, but having more in common with the orderly influences of memory and will, and that these also stimulate the centres of motion to a like initiative and thus more purposeful but unconscious action? If so, we have an explanation of somnambulism, which is founded on an evidential analogy [illegible] logical and scientific

hypothesis. So much for the theory of this strange condition. Meanwhile the necessity for its practical treatment is, with some at least, a pressing one. As regards this part of our subject, it follows from the preceding remarks that daily worries, as they are fruitful causes of sleeplessness, must, as far as possible, be controlled if sleep is to be more than a dreamy drowsiness. Some men can throw off anxiety for a time when they go to rest; others, less gifted with self-control, ponder them in their beds. The advantage of the former in every way is of course apparent. It was a prudent resolution which led the philosopher Kant to spend a quarter of an hour before he retired each night in abstracting his mind from its preoccupations; light sleepers might well adopt his method. Nor should the strictly physical causes of nerve irritation be overlooked. These, in fact, are worries which attack us through the visceral and other outposts of sensation. Late and heavy meals should therefore be avoided, for he sleeps best who retires with a cool head and digestive organs not required to add night duty to their daily task.

ROYALTY AND THE SICK.

THE Queen's subjects have had many opportunities of observing her concern for their welfare, especially when accident, illness, or other trouble has occurred to prove the quality of her sympathy. It was characteristic of Her Majesty that during her stay in Edinburgh she did not forget to visit the Hospital for Incurables. Had she found other engagements too pressing to admit of this, no one would have felt surprised. The lot of the permanent invalid, monotonous and sad as it must be to himself, has in its very permanence a tendency to dull somewhat the sense of fellow-feeling in those about him. His ailment has become his usual, one might say his normal, state. The highest promise of skill does not ensure him a remedy for all his ills. Hope there still is in such cases, it is true; but it is the hope of partial, not perfect, recovery on this side of the grave. To be, in some degree at least, forgotten is one considerable trial of the confirmed invalid, and his happiness necessarily consists in large measure of that courageous faculty, contentment. That some invalids do show this faculty in a marked degree is daily manifest; and as we think of this, the Royal visit seems, with a grace other than that of mere charity, or even sympathy, to recognise its obscure but real merit.

THE PORT OF LONDON.

THE steady work of supervising vessels and docks with regard to their sanitary arrangements has been materially favoured by the absence of any home epidemic which might have made special demands on the time of the sanitary officers, and by the impetus which cholera in Europe has afforded. There still remains much to be done by ship-owners and shipbuilders to secure the health and well-being of the crews, but Dr. Collingridge announces that structural alterations having this end in view are steadily on the increase. Improvements are also being carried out in the docks. One of the matters as to which some progress has been made, but concerning which much more precaution is needed, is the bringing home of the clothes and effects of seamen who have died abroad, and Dr. Collingridge has urged that the Board of Trade should require captains and agents to refuse such effects unless they are satisfied, as the result of a proper certificate, that they have been disinfected, or that the disease from which the seaman had died was not infectious. The matter is one of importance, and we are glad to learn that increased attention is being given to it, and that the number of instances in which infected clothing is brought home is steadily diminishing. With regard to the destruction of [redacted] difficulty has arisen as to eggs, which a metropolitan authority has recently decided to be neither "fish, flesh, nor fowl." If eggs are to be dealt with satisfactorily, it may be necessary to refer to them specially in any amendment of the law; but fortunately the odour of a bad egg, as a rule, suffices to prevent its being used as food. Referring to the pollution of the Thames by the outfall sewers of the metropolis, Dr. Collingridge attributes the comparative absence of complaint during the past summer to the cool, wet season; and he states that when for a week or two the weather had been hot the river became discoloured and offensive as formerly, and this notwithstanding the treatment to which the sewage is subjected. He also points out that the recommendation of the Royal Commission that no crude sewage should be discharged into the Thames at any point above the Nore appears likely to remain a recommendation and nothing more.

THE PERILS OF A JOCKEY'S LIFE.

THE melancholy death of that incomparable horseman, F. Archer, tragical as it was, forms a painful sequel to a career of great brilliancy. It may be said that the lamented deceased had, by his professional reputation in one of our national sports, become known at least by name in every part of the civilised world. It is not our purpose or desire to say one word against a pastime encouraged alike by great and small, the peer and the peasant, the ermined judge and the criminal over whose fate he holds the scales of justice; but we would fain direct attention to the abuses of Nature's laws incidental to the prosecution of an occupation which under the most favourable circumstances is not free from risk. It has been truly said that the love of money is the root of all evil; and in the great majority of cases the desire to cast the hazard for fortune has a determining influence directly or indirectly upon the mode of life demanded of a jockey possessed of the desire to shine in the eyes of the giddy and thoughtless world. Little does the great multitude guess how dear a price a jockey pays for the encouraging shout that cheers him in his struggle, and the popular applause that greets his victory. It is not going too far to say that the sufferings and privations entailed by a severe course of training, protracted over several years, are, on physiological grounds, certain to jeopardise health, even if they cannot be proved to sacrifice life. In not a few instances jockeys have been known to sicken and die from acute inflammatory mischief, brought on by exposure to cold whilst their physical powers are at the lowest line of resistance, or by repeated chills—"cold upon cold"—they have fallen at last victims to that fell disease phthisis. Such was poor young Constable's fate. Unfortunately, too, the sweating and wasting required to bring down the weight of a jockey in a short time in order to enable him to ride in a race is often entailed on those who are constitutionally ill-fitted to withstand the shock—for starving and running and sweating are no mean factors in producing shock—to which they are submitted. It was little short of monstrous, and nothing short of cruel, that F. Archer should, by the necessities of his professional engagements, be required to reduce his weight from over 9 st. to 8½ st., in order that he might be enabled to ride St. Mirin in the Cambridgeshire of 1886—a race which will be memorable as the one to take part in which Archer subjected his frame to a strain that in all probability was never recovered from. According to a contemporary, "typhoid fever" was assigned as the last illness from which the great jockey suffered. This may be so. If it was, the onset must have been unusually insidious for delirium to have supervened on the date mentioned. The verdict of the jury was technically correct, but to the unscientific mind it carries a stigma which no one would wish to be attached

to the memory of the late popular jockey. That he was bereft of his reason cannot be doubted; at the same time, in common justice to the dead and living, we would assert that the fatal catastrophe had quite sufficient cause in recent physical strain and exposure and their consequences, without assuming that there was any underlying or latent basis of even "temporary insanity."

CHOLERA PROSPECTS.

WHILST cholera still slumbers in different parts of the continent of Europe, the time has come when we in this country may congratulate ourselves that for a third year during the European epidemic of 1884–86 we have escaped. Both in 1884 and in 1885 there were several instances in which the disease reached our shores, or even found its way inland, but this year no case has been recorded in which such importation has taken place, and there is now no likelihood that we shall be exposed to any real risk this year. It is true that both England and other countries having even a colder climate than our own have suffered from cholera during the winter months, but so far as England is concerned the disease has not commenced at so late a date in the year as we have now reached; it has rather on such occasions been an extension into the winter months of an epidemic which had previously established itself during the autumn. And even on the Continent there is a general tendency to the subsidence of cholera. In Trieste, where, since the epidemic first broke out on June 7th, there have been 882 cases and 544 deaths, the disease is rapidly disappearing. At Fiume the same applies. So also with the occurrence of wintry weather in Galicia and Hungary the disease has received a check. At Pesth cholera is abating, and only a second single case has followed the first one that was imported into Vienna. At the same time there are newly infected districts. In Italy we learn that cholera has appeared at Genoa, and that a recrudescence has taken place at certain localities in the south—as, for example, at Maddaloni, between Naples and Caserta. Then, again, there is the story of cholera in the villages of Finthen and Gonsenheim, near Mayence, to which we have referred in another column. In short, there is abundant evidence to show that there is sufficient cholera slumbering in Europe to give rise to considerable anxiety as to what may be expected next year, and whilst we may reasonably dispel fear as to any spread of the disease to this country during the coming winter, yet in view of future prospects sanitary authorities should not relax the measures of prevention which have been initiated during the summer months.

CHEMICAL RESULTS OF THE INGESTION OF DEFIBRINATED BLOOD.

DR. A. V. GRIGORIEFF publishes in the *Russkaya Meditsina* an account of a series of observations on the effect of the addition of defibrinated blood to the diet upon the metabolism and assimilation of nitrogenous matters. He made use of four different persons for his experiments, two of them being healthy and able to walk about; the other two, who were suffering from dyspepsia and in a weakly state, were confined to the wards of the hospital. During three days they were given ordinary diet, then for a second similar period part of the meat was replaced by about twenty ounces of defibrinated calves' blood, and finally a return to the original diet was made for a third period of three days. During all the time the quantity of food was noted and the amount of ingested nitrogen ascertained. The excretions were also quantitatively analysed for nitrogen, the difference between that ingested and excreted giving, of course, the amount assimilated. The results were similar in all the cases, and showed that the metabolism and assimilation had been invariably increased by the blood diet. In one case, which was that of a vigorous subject, the mean nitrogenous assimilation, which was 86·45 per cent. in the first period, increased to 89·78 per cent., the increase continuing, though not to the same extent, through the third period. In the other cases the difference produced by the blood diet was less marked. On the whole, the author thinks the treatment likely to prove useful in weakly persons, but he suggests that the culinary art must be called to our aid in order to overcome the natural distaste to such an article of diet as defibrinated blood.

DRAINAGE OF RICHMOND.

ON the 10th inst. at the Richmond Vestry Hall, Mr. Arnold Taylor, an inspector of the Local Government Board, opened an inquiry with reference to an application by the urban and rural sanitary authorities of the district, for sanction to borrow the sum of £100,000 for the execution of a joint scheme of sewerage and sewage disposal. The proposal is to lay a collecting sewer along the river bank at Richmond, and a main sewer thence to Mortlake. Another sewer would pass from Barnes to Mortlake, and these would serve to convey the whole of the sewage of Barnes, Mortlake, Kew, Richmond, and Petersham, to eleven acres of land on the river bank in Mortlake parish, where it is intended to treat it by a system of chemical precipitation and filtration, the effluent passing into the Thames. There is no serious opposition from any source, and the promoters are confident of success in getting the scheme passed by the Local Government Board.

OUR ARMY.

THE annual general return of the Army for 1885, furnished by the Adjutant-General, shows the average strength of officers to have been 7075, and of non-commissioned officers and men 190,989. Of these, 3248 officers and 88,331 men were employed at home, and the rest on foreign service. In the whole force, exclusive of officers, there were 2588 deaths and 3581 discharges by invaliding during the year, being in the ratio of 13·55 and 18·75 per 1000 of the strength. The total loss by these two causes was therefore 32·30 per 1000. The number of recruits enlisted was 68,536, and of these 19,864 were rejected on primary and secondary medical inspection, being in the ratio of 290 per 1000. The total number of recruits who joined the service was 39,552, or 577 per 1000 of those enlisted; of these 37 died and 31 were discharged as invalids within three months of the date of enlistment, making together a loss of 1·7 per 1000 of the recruits who joined. The return of the ages of the recruits who joined shows that 360 per 1000 were under 19, 261 between 19 and 20, and 370 were 20 and upwards. Compared with the preceding year this shows an increase in the proportion under 20 years of age. Their heights were: under 5 ft. 5 in., 306; 5 ft. 5 in. to 5 ft. 6 in., 206; 5 ft. 6 in. to 5 ft. 7 in., 188; and above 5 ft. 7 in., 300 per 1000. The chest measurements were: under 34 in., 345; 34 in. to 35 in., 347; and 35 in. and upwards, 308 per 1000. Their weights were: under 120 lb., 199; from 120 lb. to 130 lb., 382; and 130 lb. and upwards, 419 per 1000. We regret that the returns of crimes and punishments are unfavourable as regards the progress of temperance among the soldiers, for, compared with 1884, there has been an increase in the number of courts martial for drunkenness among the troops abroad, and the fines for drunkenness were in the ratio of 249 per 1000 of the strength, as against 235 in the preceding year. The average strength of the first class of the army reserve was 37,376, and the deaths reported were 308, or in the ratio of 8·24 per 1000; the second class averaged 7138, with 120 deaths, or [illegible] first class consists almost

entirely of men under 35, and the second of men over 40 years of age. The strength of the Militia on Jan. 1st, 1885, is stated to have been 104,380; and the deaths during the year are returned as 417, or 4·0 per 1000; that of the enrolled Volunteers is returned as 224,012, with 871 deaths, or 3·89 per 1000; but there seems reason to believe that the returns of deaths are by no means complete in either of these branches of the service.

M. PASTEUR.

M. PASTEUR has recently presented before the Academy of Sciences certain statistics and offered certain explanations of failures which require careful examination and comparison. In the absence of a detailed report it is impossible to examine very critically or compare with accuracy, but from an investigation into the figures, and a consideration of the proffered explanations, we are led to believe that M. Pasteur has successfully answered the arguments of his opponents and calumniators. The sum total of inoculated individuals has been 2490; of whom 80 were from England, 2 from British India, 18 from the United States, and 191 from Russia. Of the 1700 French persons who were treated 10 died. M. Pasteur apparently proves by statistics furnished by mayors and others that a very small minority of people who were bitten during the year 1885-86 in France did not go to him for treatment, and that of these 17 died of hydrophobia. In the hospitals of Paris the mortality from hydrophobia was 11 per annum for five years. Last year the number of deaths was 21, but since November, 1885, when the Pasteur system was introduced, only two individuals had died, and these had not been inoculated. One died after inoculation, but the treatment of this case had been under the old systems of mild injections of virus. And this is Pasteur's explanation of his failures in cases where the bites of rabid animals were received in the face and head. Most of those who underwent the mild treatment were children who had been bitten severely in the face, and it was only after a sad experience that the necessity for stronger injections was made evident. Now, in cases of severe bites in the head or face inoculations of a more intense kind, made with freshly extracted virus, are used. Alluding to the deaths of the three Russians from Smolensk, M. Pasteur stated his belief that the other sixteen Russians were saved by being subjected to more intense treatment after the deaths had proved that mild injections were useless in cases of the kind.

ANÆSTHETIC EFFECT OF OINTMENTS.

DR. TOPOROFF has published in the *Russkaya Meditsina*, an account of a series of observations made with the object of determining the absolute and relative effects of various narcotic and anodyne ointments on the sensitiveness of the skin, with reference both to mechanical and electrical excitants. The portion of the surface to be experimented on was first cleansed and moistened, and the sensibility estimated by means of a Weber's compass æsthesiometer with tortoiseshell points, the direction of the line joining these being vertical, as it is known that sensibility as tested by the compass is greater in a vertical than in a horizontal direction. When the least distance at which two points could be distinguished was determined, a drachm of the ointment was rubbed into the surface over a circular area measuring an inch and a half in diameter for ten minutes. After the lapse of another ten minutes the sensibility was again estimated, and a third time after an interval of half an hour from the end of the rubbing. The electrical sensibility was tested by means of the primary current of a Spamer's induction apparatus, the secondary coil being [illegible] primary, so as to increase the strength of the current according to the divisions of a scale. With a 1-to-8 belladonna ointment the tactile sensibility was always diminished, the mean difference being 0·6 centim. at ten minutes and 1·1 centim. at thirty minutes. When lanoline was used as a basis instead of lard, the mean diminution was only 0·55 centim. at ten minutes and 0·95 centim. at thirty minutes. With hyoscyamus, aconite, and conium much the same results were obtained, but the degree of anæsthesia produced was slighter. With chloroform ointment of the same strength (i.e., 1 to 8), the diminution was 0·66 centim. at ten minutes and 0·8 centim. at thirty minutes. In this case the substitution of lanoline for lard in the composition of the ointment produced a markedly diminished effect, the mean figures being 0·3 centim. at ten minutes, and 0·62 centim. at thirty minutes. Turning now to ointments made of powdered substances, it was found that, so far from any anæsthesia being produced, the sensibility was actually increased by them. This was the case in almost all the observations made with hydrochlorate of morphia ointment (1 to 60), opium ointment (1 to 19), and bromide of potassium ointment (1 to 6), the augmentation being less when lanoline was employed than when the ointments were prepared with lard. No very decisive results were obtained by the observations of the effect of narcotic ointments on electrical sensibility, but the author instituted a series of observations in order to determine the influence of the friction with lard and lanoline alone, and found that ordinary sensibility was invariably increased, for a short time at least, the mean figures being, for lard, 4·25 centim. at ten minutes, and 1·75 centim. at thirty minutes. In the case of lanoline, the mean increase at ten minntes was 5·5 centim., but no effect at all was detected at thirty minutes. The author remarks that the hyperæsthesia apparently produced by the ointments prepared with powdered narcotic substances—morphia, opium, and bromide of potassium—is therefore probably due to the mere friction with the lard, the medicament being unable in the form of powder to penetrate through the skin. According to these researches, lanoline would appear to be a less advantageous basis for anodyne ointments than ordinary lard, the difference in favour of the latter being especially marked in the case of chloroform ointment. The effect of the ointments seemed also to vary considerably with the region of the body experimented on. Thus, while the diminution produced by chloroform ointment on the forehead is stated as ·95 centim., the figure indicating its effect on the inner surface of the thigh is only 0·1 centim.

PENNY DINNERS.

THE Central Council for Promoting Penny Dinners have published this year a treatise of much interest in connexion with the working of their scheme. It consists for the most part of essays, in which the difficult question of gratuitous, or virtually gratuitous, relief in the shape of food for starving school children is exhaustively discussed. The leading principle, that regular feeding is absolutely necessary for a child whose education is compulsory, is plainly set forth and proved by the writers of these various papers. In a large number of cases the utter impossibility of applying it has also been but too fully demonstrated. The question as to how this difficulty shall be met resolves itself into three sections as it affects the children: firstly, of those who from no fault of their own are too indigent to buy sufficient food for their families; secondly, of those who carelessly neglect them; and thirdly, of the drunken or vicious, whose poverty is due to their own misconduct. In each case the children suffer by the misfortune or fault of their parents at an age when they can do little to provide for themselves. As might be expected, there is some difference of opinion among the writers of these various papers as to the best remedial

method. We may shortly summarise these views as follows: Every necessitous child unable to pay for the daily meal should be supplied with a penny for this purpose out of the charitable fund of the Central Council. Where neglect or vice is the cause of poverty, the law should be invoked to determine the liability of parents, and the child, if advisable, transferred to an industrial school. In every instance discretion is necessary to prevent an abuse of charity; but this a careful teacher, with the information gained from School Board visitors, should be able to exercise. The plan here detailed involves no great expenditure for its execution. There is much to be said for it, and public opinion will not, we hope, fail to recognise in a substantial manner in the future, as in the past, its deserving claim to consideration.

CHOLERA IN GERMANY.

THE current issue of the *Berliner Klin. Wochenschrift* (No. 45) contains a communication from Dr. Hueppe respecting the outbreak of cholera in the neighbourhood of Mayence. It appears that about the middle of September cases of a choleraic character appeared at Finthen and Gonsenheim, some of which were fatal. Asiatic cholera was unsuspected, and the last fatal case, on Oct. 27th—that of a nurse—was officially declared at Mayence, upon the authority of the medical men who made the post-mortem examination, to have none of the characters of that disease. But, as Dr. Hueppe points out, the post-mortem examination alone may not suffice to diagnose the disease, the anatomical changes being perhaps but slight. He therefore regrets the premature publication of such an opinion, which might shake the public confidence in the profession, supposing the statement proved erroneous; and in the present instance he was on Oct. 29th given some material from the case in question, and discerned therein Koch's comma bacillus, and had clearly distinguished it from allied organisms (such as the Finkler-Prior bacillus). This discovery was confirmed by Dr. Gaffky of the Imperial Hygienic Institute and Dr. Reissner. Dr. Hueppe writes therefore to correct the misapprehension abroad upon the nature of this epidemic, and suggests that the cholera may have been introduced from Italy or Hungary by commerce or travellers. Fortunately the epidemic has remained localised, and Dr. Hueppe's action may do good by putting the sanitary authorities in other parts of Germany on the alert.

WINDOW-CLEANING FROM THE OUTSIDE.

ONE might well think that the teaching of experience was hardly needed to impress on servants and householders the culpable recklessness of having upper windows cleaned from the outside by someone standing on the ledge. A recent fatal accident incurred in this way unfortunately points to an opposite conclusion. It is sincerely to be hoped that this sad occurrence will give the death-blow to a custom which, in spite of general condemnation in the past, still survives as a perpetual menace to personal safety. Law is not wanting to restrain it, for the practice in question is illegal. The plea of necessity cannot as a rule, if ever, be urged in its justification, for the work can be otherwise done, and done as efficiently. Mere hurry and convenience are its inadequate excuses. On the other hand, one thoughtful glance is enough to reveal the many risks of accident which it entails. We note with satisfaction that the mistress of the poor girl whose case we have mentioned was in no way to blame for its fatal termination, her housemaid, who was very young, having acted against orders. Regrets are now, however, unavailing, and must give place to the consideration of preventive measures for future use. Of such one will naturally be looked for in the strict attention of the police to cases of this kind. An inventor whose patent appears in the Edinburgh Exhibition professes to have devised another, in the shape of an appliance which, when fastened on to a window frame, allows it to be turned inward for cleaning and replaced as required.

ENGLISH MEDICAL CLASSICS.

THE rapid progress and keen concentration bestowed on working out new facts in modern medicine has for a time arrested our backward glance to the work of our forefathers. Some, indeed, consider the task superfluous, and declare that medicine has no history worth recording before nearly the middle of this century. Others admit that there is an interest, and regret that they cannot spare time to make acquaintance with the literature of the past. No doubt many of the old authors are hardly worth acquaintance, but still among much rubbish undoubted gems are to be found. The chief interest, however, that attaches at present to the study of medical history is the help it is likely to afford in giving us an insight into the natural history of disease: how some diseases have died out, how others have been modified, and how some new ones have been introduced; and what influence the various conditions of social life, of agriculture, drainage, &c., have had in bringing about such changes and modifications. In fact, the time seems to have come when we are sufficiently advanced to investigate by the light of modern pathology many of the difficult problems of the past. What, for instance, was the disease that ravaged France in the fifteenth century known as *trousse gallant*? was it unrecognised syphilis, or was it related to the *pellagra* of Italy, or, as some of the symptoms would suggest, was it *beri-beri*, now known only in tropical climates? What from its symptomatology was the probable nature of the sweating sickness? Then again, as regards recognised epidemical diseases—have they undergone any modification in type within the last few centuries? Cannot the descriptions of some of the new diseases be recognised in works of some of the older authors?—besides many other questions of interest too numerous to particularise here. The task is not so difficult as would at first sight be supposed. The older physicians, if they lived in prescientific days, were careful and accurate clinical observers, and it is not difficult to follow them in the account of their cases. Thus Dr. Norman Moore has recently established without doubt, from the records of the physicians, the fact that Prince Henry, son of James I., died of typhoid fever, and not, as had been hitherto supposed by some, of consumption, and by others of poison. Again, too, in Willis's description of the epidemics that broke out in the Royal and Parliamentary armies, 1645, we can easily distinguish the cases of typhus from the cases of relapsing fever; whilst in an outbreak occurring about the same year in a farmhouse he gives an excellent account of typhoid fever attacking members of the family in succession. It appears to us, then, a pity that some attempt is not made to bring forward some of the old English medical classics in a useful and easily accessible form—for instance, such works as Dr. Caius' "Counseil against the Sweate," Glisson's treatise on Rickets, and Sydenham on Gout; whilst an abstract of recorded outbreaks of epidemic disease by leading medical authorities from the earliest times to the present would be most useful, especially as the older authorities were always careful to note what they called the "epidemic constitution" of the year—that is, the most important meteorological conditions that were observed. Again, there is another piece of work that ought to be undertaken: in Caius College there exists a number of MSS., some of them dating from the thirteenth century, collected and presented by the illustrious founder, Dr. Caius. Some of these manuscripts [illegible] transcripts or commentaries of well-kn[illegible] &c.; but some

are original compositions, graduation theses, and such-like, and full of interesting details. The most important and valuable ought to be published; but who will undertake the task? The cost would not be great, since none of the MSS. are of great length, and there are plenty of men who would be willing to supervise the editions as a labour of love. Perhaps, if the matter were properly brought under the notice of the Sydenham Society, they might feel disposed to publish some of the more important of these old MSS. from time to time.

THE SANITARY STATE OF WEST COWES.

IT is with regret that we have read the report of the reception by the West Cowes Local Board of Health of Mr. Spear's report on the very serious and fatal prevalences of diphtheria which have occurred in that town. The recommendations attached to the report essentially agree with those which have been made by their own medical officer of health, by a previous medical inspector, and by an engineer inspector from the Local Government Board. But the chairman, in producing the report, stated that, with the single exception of the suggestion as to the provision of hospital accommodation, the recommendations were not worth the paper they were written on. The question of the existing system of sewerage is now being inquired into; but as regards such matters as the very defective condition of the house-drains, which has been officially under notice ever since 1881, and the need of a sufficient water-supply to be laid on at constant pressure from a source, and under conditions beyond risk of contamination, it was decided simply to write to the Local Government Board, and say that the several items in the report had been carried out. We doubt the policy of such disregard of an important document, and we think that the public will look for something more than this before anything like confidence is restored as to the healthiness of West Cowes. Had the sanitary authority felt able to dispute the matters of fact detailed in the report, they would doubtless have done so. As it is, they evidently prefer to adopt that which, in our opinion, is a very injudicious course.

THE BLOOD AT BIRTH.

DR. F. KRUGER of Dorpat has been investigating (Virchow's *Archiv*, 106, Hft. 1) the condition of the blood of the fœtus at birth, and comparing its properties and composition with the maternal blood. The subject has been studied before. In some respects the present research confirms the previous ones—notably those of Becquerel and Rodier. Like those authors, Krüger finds a very slight comparative increase in the total solid constituents of the blood at this early period of existence; but he shows that in fibrin fœtal blood is markedly deficient—viz., about one-third of that contained in maternal blood. The amount of hæmoglobin is about the same as that of maternal blood, but it increases in quantity in the infant for some time after birth. Unlike the adult, there is no notable difference in the composition of blood in the two sexes. Fœtal blood at the moment of birth has a great tendency to coagulate, but coagulates slowly—i.e., the process begins early, but continues for a long time before it is completed. Inquiring into the reason of this, he directed attention to the factors which, according to Schmidt, are essential to coagulation—viz., the leucocytes and blood-plasma. Three possibilities presented themselves: either there is a diminished activity of the blood-plasma in causing the liberation of "ferment" from the corpuscles, or the number of leucocytes must be less than in the adult, or these corpuscles part with the ferment less readily. On the first hypothesis, coagulation ought not to be quickened on the addition to the [illegible] corpuscles; but the contrary is the case. Nor is there any diminution in leucocytes, the absolute and relative number per cubic millimetre being the same as in the adult. It is concluded, therefore, that the reason of the slowness of coagulation of fœtal blood depends on the nature of the white corpuscles, and their slighter readiness to break up.

THE BRITISH EYE HOSPITAL AT JERUSALEM.

OUR readers are aware that we take a lively interest in all charitable and religious uses of Medicine among less favoured nations, all the more so where all mere sectarianism and proselytism are kept in abeyance. With this disposition we have read with great pleasure last year's report of the Eye Hospital established in Jerusalem by the Order of St. John on a site given by the Sultan. The report is written by the resident surgeon, Mr. John Hovell Ogilvie. The hospital is resorted to by the poor of all parts of Syria. The only painful part of the report is that which shows the disproportion of its accommodation to the demand. Accordingly, it happens that many persons who walk from great distances—possibly Jaffa, or Gaza, or the Desert,—plodding on in the hope of being admitted with what otherwise may be incurable disease, find no room for them. Mr. Ogilvie has found it so difficult to reject that he has sometimes had eleven cases in the hospital, where there is only accommodation for four. This want of accommodation cannot long survive when the facts are known. The work done is of the best. The cases are carefully classified in the report, and the results of treatment are given with obvious candour. No less than 121 have been admitted into hospital. The new cases seen at the dispensary were 3238; the total number of consultations was 13,462. Most of the cases admitted were such as needed operation; 231 operations were performed, including 55 for the extraction of cataract, and 37 for making artificial pupils where dense and extensive opacities of the cornea, giving little hope of success, existed. Of the cataract cases, 48 were successful. The iridectomies were not so satisfactory, but, considering the nature of the cases, favourable results were obtained. The cases of ophthalmia—catarrhal, chronic, granular, granular with pannus, and ophthalmia tarsi — reach nearly 1500. Cleanliness and disease are the only conditions of admission; the requirement of cleanliness has become extensively known, and had a marked effect. The patients are Protestants, Greek and Armenian Christians, Latin Christians, Jews, and Mahommedans. Frequently Christians, Jews, and Mahommedans have occupied the same ward, verifying the noble aim of the Order, "*Pro fide, pro utilitate hominum.*' We appeal to Jews, Christians, and Mahommedans, who have the means, to convert these four beds into twenty, and so fulfil the old satisfaction of Job, "I was eyes to the blind."

DUBLIN DAIRY YARDS.

THERE has recently been published a paper by Dr. C. F. Moore, of the South Dublin Union, which was read before the Academy of Medicine in Ireland. This paper gives a very unsatisfactory account of Dublin dairy yards. Dr. Moore points out that the importation of pleuro-pneumonia into England was due to disease received from Dublin, and he attributes this occurrence to the neglected condition of cowsheds in that city. After quoting Ferrand and Klebs, who traced the prevalence of diphtheria to offensive dung-heaps, and the opinion of the former that manure should be kept in closed wells made of stone and glazed with bitumen, so constructed that all fluid filters away from the solid matter, he described the conditions frequently met with in Dublin. The manure heaps, he says, are often placed in the angles of yards, one or more of the walls enclosing the manure being those of a dwelling-house or cowshed, or

stable, or abutting on a street or lane; and though he comments on the comparative absence of diphtheria from that city, he states that he has in many instances traced the connexion between disease of various forms to proximity to manure-heaps. His conclusion is that cattle should not be kept in towns of any considerable size, and that Dublin is so conveniently situated with regard to suitable farm land on both sides that it could easily dispense with the housing of cattle within the borough boundary.

HOSPITAL CO-OPERATION WITH PROVIDENT DISPENSARIES.

DR. RENTOUL has been again arguing for the establishment of co-operation between hospital authorities and provident dispensaries. He argues that the creation of these in Liverpool would diminish pauperism. He says that in Manchester seven out of nine provident dispensaries are self-supporting. In Manchester, in four of the hospitals, investigations are made by special inspectors into the means of applicants, and if they are found to be receiving wages above a certain scale they are considered ineligible for gratuitous relief, and are referred to a provident dispensary. The scale is as follows: Man and wife, 18*s.* per week; single men or women, 12*s.*; each child, 1*s.* 6*d.* per week. This system has reduced the number of unfit applicants. Dr. Rentoul makes a statement as to the cost of out-patients to hospitals on the high authority of Mr. Nixon, the accuracy of which we venture to question—viz., that the average cost of each out-patient is 4*s.* per week. We cannot understand or believe such a statement, which is greatly at variance with other testimony on the subject. What is there in the medicine or anything else given to the *out-patient* that can cost 4*s.* per head per week? According to Dr. Rentoul there are 147 provident dispensaries in England, of which 40 are in London. Their benefit members are 286,162, paying £50,909, of which £34,222 were paid to a medical staff of 370. This would give about £92 to each medical man. Provident dispensaries are undoubtedly beneficial to the working classes and the public. It is not quite so clear that they have at present profited the medical profession, who generally do a great amount of work in them for very little money, and this injustice must be remedied.

THE AUSTRIAN MEDICAL ASSOCIATION.

THE Austrian Medical Association, which now comprises twenty-six branches, with a total of 4500 members, recently held its seventh annual meeting at Innsbruck, and resolved to petition the Government to make vaccination obligatory throughout the empire by imperial statute, also to restrict the privilege of private practice to medical men who have already served in a hospital. The Association expressed an opinion that considerable changes were desirable in the regulations concerning the training of medical students; and, lastly, a request was preferred that a law should be made assigning substantial pensions to the widows and orphans of medical men who might meet with their death through attending to their duties during an epidemic.

CHROMIC ACID v. GALVANO-CAUTERY.

M. POSKIN has reported to the Liège Medical Society on his use of chromic acid in more than 100 cases of diseases of the nose, pharynx, and larynx, as showing the great value of this powerful caustic in hypertrophy of the turbinated bones, polypi, and granulations in the ears. He remarks that, as it is a violent poison, acting especially on the gastro-intestinal tract, it is necessary to exercise great caution, especially in pharyngeal and laryngeal cases; and he eschews it altogether in the case of children. Its action may be neutralised by a weak solution of carbonate of soda. The best way of employing chromic acid is to heat moderately a very small crystal on a silver probe, to which it will adhere as a dark-brown coating. If the heat is too great a green oxide is formed, which is devoid of any caustic action. M. Poskin finds that chromic acid compares favourably with the galvano-cautery, both on account of the cost and the convenience with which it may be applied. It is, he thinks, also quite as efficacious and less dangerous. The eschar which is produced falls in from three to five days.

THE LATE SURGEON-MAJOR T. R. LEWIS.

THE friends and colleagues of the late Surgeon-Major T. R. Lewis, Assistant Professor of Pathology in the Army Medical School, being anxious to commemorate the life and works of one who contributed so largely to scientific medicine, have prepared a circular for distribution (of which we have received a copy from the secretary) inviting subscriptions for this purpose. They suggest as the most fitting memorial a reprint of his numerous scientific reports and papers, with his portrait as a frontispiece and prefaced by a biographical notice. It is proposed to issue a copy of the reprint to each of the subscribers, a list of whom will appear in the preface to the volume. A committee has been formed under the presidency of Sir Thomas Crawford, K.C.B., M.D., Director-General A.M.D., for the purpose of carrying these proposals into effect, the secretaries being Surgeon-Major G. E. Dobson, F.R.S., and Surgeon H. S. McGill, M.S., and the treasurers Messrs. Holt, Lawrie, and Co., of Whitehall-place, S.W.

WESTMINSTER UNION AND DR. JOSEPH ROGERS.

AT the meeting of the Board of Guardians held on Friday, the 5th inst., the question of the superannuation grant to Dr. Joseph Rogers, of which due notice had been given on the night of his resignation, came up for discussion. The board was unanimous in deciding that the grant should be made, the only difference of opinion being whether his service at the Westminster Union should alone count, or whether it should embrace his tenure of office at the Strand also. It was eventually decided by a large majority in a very full board, that the twelve years he was "medical officer" at the Strand Workhouse should be estimated in virtue of the fact that the parish of St. Anne—which had been taken out of the old Strand Union and joined to St. James's—was during that period under his professional charge. We understand that the Local Government Board, who had been previously appealed to, has sanctioned this procedure of the Westminster Board. Dr. Rogers is to be congratulated on this recognition of his services in the past, which were most handsomely referred to by the guardians present.

DRUNK OR SOBER?

THIS is the complementary question to that other important one, "Drunk or dying?" When the answering of this question is left to policemen, because there is no competent medical practitioner within call to ascertain the facts, the decision is very regrettable; but when a medical opinion is given, and an unskilled judgment is preferred to it, the choice is not only unreasonable, but reflects discredit on the person making it, albeit those persons chance to have magisterial authority, and enjoy the dignity of justices of the peace. We entirely sympathise with the feelings of Mr. Pearce, of Brierly Hill, who has had his opinion set aside by the "great unpaid" in favour of that of the police in the case of a man accused of being drunk, whereas he was sober. It is, or rather let us say it ought to be, beyond the province of a magistrate to reject a medical

opinion on a point of this sort unless there be ground for thinking that the opinion given was not in *bona fides*. It is not for justices to determine the accuracy of a professional opinion: they may decide that it is falsely given, but not that it is false in itself. This is a view of the matter which it is desirable to enforce.

DEATH OF A PASTEUR PATIENT.

A MAN named Wilde met with an abrasion of the skin on Oct. 1st, whilst tending a patient named Oates, who died from hydrophobia a day after the slight accident to Wilde. The circumstances seemed to indicate the advisability of Wilde's being sent to Paris to receive treatment at Pasteur's hands. The abrasion on the hand was freely cauterised by Dr. Foote of Rotherham with nitrate of silver, and the patient Wilde underwent a course of treatment at Paris, receiving nineteen inoculations in all. He returned to England at the end of two weeks, and remained in good health till Oct. 30th, when his fatal illness began. The clinical history, as detailed by Dr. Foote, lends no support to the belief that death resulted from hydrophobia. In fact, the case was regarded by him as an ordinary one of "congestion" of the lungs, the result of a chill. In the face of this evidence it is impossible to include this case in the list of failures of M. Pasteur's method. As will be seen in our correspondence columns, Dr. Hime seems to have satisfied himself of the absence of rabies in the case.

OVERHEAD WIRES.

THE "Works and General Purposes Committee" of the Metropolitan Board of Works has been good enough to agree with a Select Committee of the House of Commons in the opinion that something should be done about the overhead wires of the telegraph and telephone systems. This is encouraging, and ought to prove consoling to the surviving victims of accidents, and the friends of sufferers generally, during the long period which is only too certain to elapse before any serious step is taken in the matter. From a practical political point of view, we must confess that this accord between two "authorities" in condemning an easily remediable evil does not appear likely to expedite a much-needed reform. Being agreed on the subject, the authorities concerned will probably shelve the question at issue. It is, then, necessary that the agitation commenced in the interest of public safety should be promoted with increased vigour. Doubtless there will be plenty of illustrative narratives of fact available for the purpose of argument as soon as the winter snows make their appearance.

INTRA-PULMONARY INJECTIONS IN PHTHISIS.

DR. JOHN BLAKE WHITE, of New York, advocates the plan, which has been adopted by Gougenheim, Shingleton Smith, and others, of injections into pulmonary cavities in phthisis, believing that by their use life may be prolonged and sometimes saved. He finds the following formula to occasion the least amount of irritability when injected: atropia, one-third of a grain; sulphate of morphia, two grains; tincture of iodine, three drachms; carbolic acid (pure), twenty minims; glycerine, one drachm and a half; alcohol (diluted 20 to 30 per cent.), an ounce and a half; the quantity injected at a time being from fifteen to thirty minims. He employs a syringe capable of holding one drachm of fluid and provided with needles, which are perforated near the tip in four places, so that the injection may enter the cavity in the form of spray. Eleven cases are reported (*Med. Record*, May reprint), and although in several the immediate effect appears to have been the excitement of violent coughing, in most there was a marked improvement in the general condition, with diminution of expectoration [illegible] the physical signs.

GENERAL PRACTITIONER CANDIDATES.

WE are asked by a correspondent to publish the names of candidates who are in general practice for the convenience of those general practitioners who wish to be represented by men of their own order. In England voters can scarcely go wrong in this matter, the majority of the candidates being in general practice. The list will be found in last week's issue of THE LANCET. In Scotland and Ireland respectively there is some risk of the single seat being appropriated practically by the nominees of the medical authorities who have hitherto monopolised the Medical Council. This will be simply lamentable; but it will be the fault of the practitioners themselves. Let there be no mistake upon this point.

THE IRISH ELECTION AND THE SOUTH-EASTERN MEDICAL SOCIETY.

A CORRESPONDENT seems embarrassed by the importance attached to the vote in favour of *two* candidates for the one Irish seat recorded at a meeting of a society called by a contemporary "the South-Eastern Medical Society" of Ireland. He has ascertained that the society exists, and states that it consists of seven individuals. We can only advise our Irish brethren to disregard all societies and vote for a representative of general practice in Ireland, and not to expect commiseration if they do not do so and find the seat secured by a high official of one of the Dublin bodies, who have hitherto monopolised the Irish seats ever since there was a Council.

CASE OF EPULIS IN CONNEXION WITH A WISDOM TOOTH.

MR. DAVID HEPBURN reports a case, under his care at the Dental Hospital of London, of a very vascular, friable, epuloid growth springing from the cyst-wall of an impacted lower wisdom tooth. The patient, a house painter, aged eighty-two, also complained of neuralgic pains over the side of the head and a sense of numbness along the jaw. There was loss of sensation in the region of the mental foramen. The tumour was removed, and a fortnight later another had formed, which was also excised, when a wisdom tooth was detected. This, being with considerable difficulty extracted, was found to be surrounded with a thick membrane, and the pedicles of the tumours were distinctly visible upon the surface. When seen a few days later, the neuralgia had entirely ceased, but there was no return of sensation.

RAPID MECHANICAL DILATATION IN DYSMENORRHŒA.

DR. WILLIAM GOODELL, Professor of Gynæcology in the University of Pennsylvania, strongly recommends rapid dilatation of the cervix by instrumental means in cases of dysmenorrhœa and sterility. It is, he finds, much more satisfactory than treatment with tents. In one case, where the pain was so severe that two physicians were in attendance giving chloroform for forty-eight hours, a single dilatation effected a cure. "No serious symptom," he says, "has ever followed, though the dilatation is carried to the extent of an inch or an inch and a quarter. In four or five cases tears have resulted, but never of sufficient magnitude to require a suture."

COCAINE IN ACUTE PHARYNGITIS.

DR. KURZ mentions in the *Abeille Médicale* that having a severe case of phlegmonous inflammation of the pharynx, producing dyspnœa, violent headache, and great pain in the neck, which was unrelieved by chlorate of potash, salicylic acid, quinine, and ice, he painted the pharynx with a 4 per cent. solution of cocaine. The first application caused a

choking sensation and vomiting; it was repeated at the end of five minutes, and this time no reflex actions appeared. After two more applications the local symptoms disappeared as if by magic, the extreme tumefaction becoming scarcely perceptible, and the voice, respiration, and power of deglutition returning. The cure was ultimately completed by a 2 per cent. resorcine spray.

THE RELATIONS OF THE APOTHECARIES' SOCIETY TO THE ENGLISH CONJOINT BOARD.

WE understand that a committee is being formed to arrange for a general meeting of the profession (to be held at an early date) to obtain a further proof of the feelings of medical men generally in regard to the relations of the Society of Apothecaries and the Conjoint Board, and that the following gentlemen have consented to act as honorary secretaries:—Mr. J. Wickham Barnes, hon. secretary, Poor-law Medical Officers' Association; Mr. W. C. Steele, hon. secretary, Members' Association; and Mr. W. G. Bott, hon. secretary, Association of General Practitioners.

At a meeting of the Council of the Poor-law Medical Officers' Association, held on November 4th, the resolution adopted at the conjoint meeting of the Fellows and Members of the Royal College of Surgeons in relation to the Society of Apothecaries and the "Conjoint Examination," was submitted for consideration, when it was unanimously resolved that this Council, heartily concurring in the said resolution, advises all Poor-law medical officers to use their efforts to obtain for the Society of Apothecaries its proper position in relation to the Conjoint Board.

FOREIGN UNIVERSITY INTELLIGENCE.

Prague.—Professor Bandl, who has just been appointed to the chair of Gynæcology, has been obliged by ill-health to cease lecturing. Bacteriological classes have been established under Professor Soyka in the German University, and under Dr. Illava in the Bohemian University, for the purpose of giving instruction in bacteriology to all the district medical officers in Bohemia, who by a recent regulation of the Government are required to pass through a course of practical bacteriology.

Freiburg.—The new lecture theatre for anatomy and the newly erected zoological institute have been opened for use since the beginning of this session.

Königsberg.—Next year an additional Extraordinary Professor of Medicine is to be appointed.

Marburg.—Professor Dr. A. Wigand, Director of the Botanic Garden and of the Pharmacognostic Institute, has died, at the age of sixty-five. He was engaged on the fourth edition of his "Pharmacognosis."

AT the meeting of the Society of Medical Officers of Health, to be held on Nov. 19th, the Council will present a report on a communication recently addressed by the Commissioner of Metropolitan Police, on the subject of disinfection of public conveyances after use by persons suffering from infectious disease. Also on a recent report of the General Purposes Committee of the Metropolitan Asylums Board on the subject of Contract with Metropolitan Sanitary Authorities for the reception into the Board's Hospitals of persons suffering from infectious disease, and who are not paupers. Members are invited to bring forward subjects of interest for discussion.

THE Town Council of Astrakhan has awarded the widow of a Russian medical man, whose life was sacrificed during a recent epidemic through his devotion to his professional duties, the sum of £300, and has also undertaken to educate his son.

THE Vice-Chancellor of Cambridge University has communicated to the Senate a letter which he had received from the Attorney-General, to the effect that Mr. John Lucas Ward had left him the sum of £10,000 to be spent "in the promotion, without regard to sect or party, of scientific and literary research, or of either of those objects, in Cambridge or in the metropolis, or in both these places." After consultation with Professor Huxley, Sir James Paget, and several others, a scheme has been formulated, the fund to be called "The John Lucas Ward Fund," and to be devoted to the foundation of studentships in Pathology, open to males or females. It is also expressly set forth that studentships shall not be awarded as the result of a competitive examination, but the students are to be elected on the nomination of the Professor of Pathology.

WE are asked to state that the members of Dr. Richardson's Committee have been actively at work in promoting his return as a direct representative on the Medical Council, and have received large promises of support from all parts of the electorate, nomination papers having been filled up for them by leading representatives of the profession from London, Liverpool, Birmingham, Hull, Wakefield, and other districts.

DR. GREEN PACHA, head of the Egyptian Sanitary Department, has returned from his inspection of the western district prisons, Toura, Bennah, Mansoura, Tantah, and Alexandria. He reports that the sanitary conditions of these establishments are disgraceful. Every forty prisoners are occupying on an average cubic space only sufficient for thirteen.

AT a meeting of the Senate of the Royal University of Ireland, held on Oct. 28th, for the conferring of degrees, the Vice-Chancellor announced that the Senate had decided to confer "the honorary degree of Master of Obstetrics upon a distinguished graduate of the University, Dr. Henry Macnaughton Jones, one of the examiners in this department."

AT the last meeting of the Border Counties British Medical Association, a resolution was passed that the Association would find the funds to enable Dr. Spurgin to obtain a new trial in his action against Mr. J. C. Nicholson, and to fight the case over again.

THE authorities of Victoria University on the 4th inst. selected Mr. Mitchell Banks, of Liverpool, as their representative on the Medical Council.

IT is stated that disquieting news of the health of M. Paul Bert, French Resident-General at Annam, has been received at the Foreign Office in Paris.

DR. SAINT, a well-known physician of Evreux, has died suddenly from eating poisonous mushrooms.

POLLUTION OF THE WATER OF LEITH.—Professor Crum Brown and Mr. R. C. Reid, C.E., have issued a report on this subject. The sources of the pollution only are dealt with, the question of remedy being for the present ignored. It is estimated that 178,000 gallons of sewage per day find a passage into the stream, and that from factories 27 tons of solid matter are discharged into the river every working day, of which 40 per cent. is organic. By the time the river reaches the boundary of Edinburgh, it is offensive and unpleasant both to sight and smell. The foul smell is chiefly due to the sewage, while the unsightly appearance, turbidity, brown colour, persistent froth, and the greater part of the deposit in the bed are caused by the discharge from the paper-

DIRECT REPRESENTATION: DR. GLOVER'S CANDIDATURE.

A MEETING of the executive committee and other friends of Dr. Glover was held at the house of Mr. Hutchinson, 15, Cavendish-square, on Wednesday last, at 5 P.M. Among those present were Mr. Hutchinson (in the chair), Sir Andrew Clark, Dr. Hughlings Jackson, Mr. Keele, Mr. Buckston Browne, Mr. Tweedy, Dr. Maclagan, Dr. Goodhart, Mr. Alfred Cooper, Dr. Wilbe, Dr. Milner Fothergill, Dr. Cholmeley, Mr. Hames, Dr. Stokes, Dr. Reid, Mr. Sibley, Mr. Wakley, Dr. Ford Anderson, Mr. Pearce Gould, Dr. Slight, Mr. Christopher Heath, Mr. Jennings, Dr. Davidson, Dr. F. H. Bastable, Mr. Henry Stokes, and others.

Mr. HUTCHINSON, in opening the proceedings, explained the object of the meeting, and expressed himself strongly in favour of the direct representation of the profession on the General Medical Council. He said that he knew Dr. Glover to be a man of great intelligence, great knowledge and experience in the special work of the Council, and of singular integrity of purpose, and he urged that to return him would serve to emphasise the great principle of Direct Representation.

Dr. GLOVER, in the course of his remarks which followed, said that the Medical Council was elected to administer an Act of Parliament by which its duties were strictly limited. The original intention of Parliament was that the Crown nominess should be general practitioners, and it was because such a selection had never been made that it became necessary to obtain the direct representation of the profession. He held that the regulation of medical education would be greatly helped by the presenceof general practitioners on the Council. Even now a man who had only attended six cases of midwifery might obtain a legal qualification to practise midwifery, and he was of opinion that such a state of things would long ago have been remedied if those who were personally acquainted with the immense importance of this department of general practice had had a share in the control of medical education. As an instance of the unsatisfactory nature of some of the work of the Council, he mentioned that the Medical Register was inaccurate, and that there was no printed list of the 800 names that had been added to the Register during the present year.

Dr. CHOLMELEY moved the following resolution:—"That this meeting cordially congratulates Dr. Glover on the expressions of support and kindness which have reached him from all parts of the kingdom and every section of the profession." He stated that he had had personal experience of Dr. Glover's very thorough acquaintance with the work of the Council. He had the most profound confidence in him as a direct representative of the profession, and he was convinced of the need of general practitioners on the General Medical Council, especially in reference to the education of medical students.

Dr. HAMES seconded the resolution, and, as a general practitioner, urged all present to do their utmost to secure Dr. Glover's return.

Mr. TWEEDY, in supporting the resolution, spoke of his intimate association with Dr. Glover in medical politics for fourteen years. Dr. Glover had followed the work of the Council so closely that his election would only convert a passive member of that body into an active one. He believed that the election of Dr. Glover and of the general practitioners would do much to secure a better recognition of the profession by the public and the State. The resolution was carried unanimously.

Sir ANDREW CLARK then moved the following resolution:—"That this meeting recognisesin Dr. Glover's position as a general practitioner, and his exceptional acquaintance with the Medical Council and its work, the very fittest qualities of a direct representative, and urges the profession to an early and hearty vote in his favour as soon as the voting papers are received." It was impossible for the Medical Council as formerly constituted to understand the needs of the body of the profession, and the Crown had failed in its duty, for, as representing the people, it ought to have nominated members of the Council from among the general practitioners. However, the profession had at last gained a great principle, and the present election would be an important crisis, for if the profession did not rise to a due sense of their [illegible] might lose the advantages supposed to be gained. He named six qualifications of a good direct representative: (1) He should be a general practitioner; (2) he should be at the present time in *bonâ-fide* general practice; (3) character; (4) acquaintance with medical reform, its past history, its future needs; (5) perfect sympathy with his fellows; (6) independence and energy. He believed that Dr. Glover fulfilled all these conditions, and he strongly felt that he deserved the support of the whole profession.

Dr. WILBE seconded the resolution.

Mr. SIBLEY expressed his cordial concurrence with the resolution. The Medical Council was not in full sympathy with the general body of the profession. In supporting Dr. Glover, a great service would be done, especially as no one else knew so well the past conduct of the Council. The resolution was then carried unanimously.

Mr. KEELE moved, and Dr. GLOVER seconded, a vote of thanks to Mr. Hutchinson for kindly lending his house for the meeting, in acknowledging which Mr. Hutchinson said his act was only a very small expression of his very strong desire to see Dr. Glover elected to the Council.

REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

[FINAL NOTICE.]

IN the last part of his annual report to the Local Government Board, Dr. Buchanan reviews the history of the pathology of cholera since the date when Koch announced, after his visit to Egypt in 1883, that this disease was identified, in so far as causation is concerned, with a definite microphyte; and in an appendix to the report are two papers by Dr. Klein on the same subject. One is a reprint of a communication which he addressed to the Royal Society last year on the Relation of Bacteria to Asiatic Cholera; and the other is a supplement dealing with the same subject, but bringing our information of it down to April of this year. We are reminded of the discovery by Koch of the comma bacillus in the alimentary canal of persons suffering from cholera, and also in certain tank-waters, and of Dr. Klein's subsequent observations, which went to show that the bacilli in question had not an unquestionable claim to be considered essential to the disease. Indeed, Dr. Klein is now disposed to regard these bacilli and other organisms found in the intestinal contents as merely incidental to the putrefaction of those matters. In Dr. Klein's supplement the story is told of the discovery of comma bacilli by Dr. T. R. Lewis in the normal fluid of the mouth, and Dr. Klein explains how he himself found the same organisms in the contents of the cæcum of perfectly normal guinea-pigs, a discovery which has a most important bearing on the experiments carried out by Koch on these and other animals, which he endeavoured to inoculate with cholera poison, and which were afterwards found to exhibit in their intestinal canals mucous flakes and numerous comma bacilli. And quite irrespectively of this, Koch's methods of operating are shown to have been perfectly capable of producing death in the animals experimented on, regardless of any cholera poisoning. The precise significance of the comma bacilli of Finkler and Prior, which are distinctly different to the organism described by Koch, and also of the bacteria described by von Emmerich and Buchner, but which have been shown by Brieger to be identical with those isolated by him from normal fæcal matter, are discussed in the report; and lastly, the experiments by Nicati and Rietsch, by van Ermengen and by Klebs, are referred to in connexion with Koch's theory of a special chemical ferment, manufactured by comma bacilli in the intestine of the cholera patient, acting as a direct cause of cholera symptoms. As to these latter, Dr. Klein observes that it is quite erroneous to regard, as Klebs does, the production of a poisonous ptomaine as peculiar to cultures of comma bacilli, since, under his own direction, Berdez has distinctly proved that in cultures of septic bacillus subtilis, as well as in cultures of Koch's comma bacilli, there is present a chemical poison having the same effect on animals as that attributed to cultures of Koch's comma bacilli. This contribution may be regarded as an authoritative summary, bringing our knowledge of the relation of bacteria to Asiatic cholera down to current date, and it shows most clearly that the question is as yet by no means solved.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5631 births and 3172 deaths were registered during the week ending Nov. 6th. The annual death-rate in these towns, which had been 19·3 and 18·5 per 1000 in the preceding two weeks, further declined last week to 18·2. During the first five weeks of the current quarter the death-rate in these towns averaged 18·8 per 1000, and was 1·9 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 11·9 in Derby, 14·2 in Birkenhead, 14·6 in Nottingham, and 15·0 in Birmingham. The rates in the other towns ranged upwards to 24·5 in Plymouth, 25·6 in Oldham, 25·7 in Preston, and 28·0 in Wolverhampton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding eight weeks from 1202 to 401, further fell last week to 368, and were fewer than in any week since the end of June; they included 102 from diarrhœa, 74 from scarlet fever, 66 from measles, 52 from "fever" (principally enteric), 42 from whooping-cough, 32 from diphtheria, and not one from small-pox. No death from any of these principal zymotic diseases was recorded last week in Cardiff; whereas they caused the highest death-rates in Preston, Halifax, and Wolverhampton. The greatest mortality from measles occurred in Halifax and Wolverhampton; from scarlet fever, in Salford, Bradford, Newcastle-upon-Tyne, and Huddersfield; from "fever," in Plymouth; from whooping-cough, in Sunderland; and from diarrhœa, in Hull, Sunderland, and Preston. The 32 deaths from diphtheria in the twenty-eight towns included 18 in London, 4 in Portsmouth, 3 in Norwich, and 2 in Manchester. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 290 and 295 in the preceding two weeks, were last week 293, and were 103 below the corrected average. The causes of 69, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Portsmouth, Brighton, and in seven other smaller towns. The largest proportions of uncertified deaths were registered in Sheffield, Halifax, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·2 and 18·6 per 1000 in the preceding two weeks, further rose to 22·1 in the week ending Nov. 6th; this rate was 4·0 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 11·1 and 18·1 in Greenock and Dundee, to 24·0 in Glasgow and 24·7 in Edinburgh. The 545 deaths in the eight towns last week showed a further increase of 85 upon the number in the previous week, and included 21 which were referred to diarrhœa, 16 to scarlet fever, 15 to whooping-cough, 10 to diphtheria, 7 to "fever" (typhus, enteric, or simple), 4 to measles, and not one to small-pox; in all, 73 deaths resulted from these principal zymotic diseases, against 72 and 83 in the preceding two weeks. These 73 deaths were equal to an annual rate of 3·4 per 1000, which was 1·3 above the mean rate from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœa, which had been 46, 25, and 22 in the previous three weeks, further declined last week to 21, of which 7 occurred in Glasgow and 5 in Dundee. The fatal cases of whooping-cough, which had been 17 and 28 in the previous two weeks, declined last week to 15, and included 11 in Glasgow. The 16 deaths from scarlet fever showed a decline of 8 from the number in the previous week; 12 occurred in Glasgow and 4 in Edinburgh. The 10 deaths from diphtheria, on the other hand, showed a considerable increase upon recent weekly numbers, and included 4 in Glasgow, 3 in Edinburgh, and 2 in Paisley. The 7 deaths referred to "fever," of which 4 occurred in Glasgow and 2 in Edinburgh, also exceeded recent weekly numbers; and 2 of the 4 deaths from measles occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 79 and 76 in the previous two weeks, further rose last week to 118, but were 2 below the number in the corresponding week of last year. The causes of 75, or nearly 4 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 20·5 and 21·9 per 1000 in the preceding two weeks, further rose to 26·2 in the week ending Nov. 6th. During the first five weeks of the current quarter the death-rate in the city averaged 22·8; the mean rate during the same period was 17·0 in London and 18·4 in Edinburgh. The 177 deaths in Dublin last week showed a further increase of 29 upon the numbers returned in the preceding two weeks, and included 12 which were referred to diarrhœa, 8 to scarlet fever, 6 to "fever" (typhus, enteric, or simple), 4 to diphtheria, 1 to whooping-cough, and not one either to small-pox or measles. Thus 32 deaths resulted from the principal zymotic diseases, against 23 in each of the previous two weeks; they were equal to an annual rate of 4·7 per 1000, the rates from the same diseases last week being but 1·8 in London and 2·7 in Edinburgh. The 13 deaths attributed to diarrhœa exceeded the numbers in recent weeks, as did the 6 deaths referred to "fever." The fatal cases of scarlet fever, which had been 7 and 10 in the previous two weeks, declined again last week to 8, while the 4 deaths from diphtheria exceeded the number in any week since the beginning of May. Four inquest cases and 3 deaths from violence were registered; and 54, or nearly one-third, of the deaths occurred in public institutions. The deaths both of infants and of elderly persons showed an increase upon recent weekly numbers. The causes of 36, or nearly 20 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

DIRECT REPRESENTATION OF THE PROFESSION ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR, Having received circulars from Sir B. W. Foster, Messrs. Wheelhouse, Richardson, Glover, Dolan, Brown, and Carpenter, who are candidates for election by the profession on the General Medical Council, we deemed it advisable "on behalf of the Association of General Practitioners," to obtain categorical answers to the following questions, which are of vital importance to the general practitioner, and we now ask your readers to give them careful study and consideration before recording their votes.

Question 1.—Are you in favour of penal legislation directed against unqualified practitioners?

Question 2.—Are you in favour of the protection of the profession, by the Council, against unqualified practice?

Question 3.—Are you in favour of the abolition of the Apothecaries' Society?

Question 4.—Are you in favour of the scheme for granting a Doctorate in Medicine which is before the board of the conjoint Colleges?

Trusting you will favour us by inserting this correspondence.

We remain, Sir, yours, sincerely,

H. W. VERDON, M.D., F.R.C.S.
W. GIBSON BOTT, L.R.C.P., M.R.C.S.

61, Kennington Park-road, S.E., Nov. 9th, 1886.

14, Temple-row, Birmingham, Nov. 4th, 1886.

MY DEAR SIRS,—I am very glad to answer the questions you send me on behalf of the Association of General Practitioners:—

1. I am in favour of penal legislation directed against unqualified practitioners, both in the interest of the profession and in the interests of the public at large.

2. I am in favour of the Council using all the powers they have, and also in favour of extending their powers against unqualified practice.

3. No, certainly not.

4. Yes. I have for years advocated some scheme for granting the Doctorate in Medicine to all practitioners able to pass the [redacted] I have myself felt the

injury inflicted by our present system on men who may have chosen a medical school for their education unconnected with a university. I am, therefore, most strongly in favour of any scheme that will give the Doctorate to men who can pass the examinations irrespective of the school at which they have been educated.

I hope these answers are explicit enough for your purpose.

Yours very truly,

Messrs. Verdon and Bott. (Signed) B. WALTER FOSTER.

Hillary-place, Leeds, Nov. 2nd, 1886.

GENTLEMEN,—I am very glad, and I thank you, that you give me an opportunity to lay before the Association of General Practitioners my views upon the four questions submitted to me in your letter of this morning, and I shall be glad if, when the opportunity comes, you will make my replies known to the Association.

1. Yes, I am. During the whole time I have acted as a member of the Medical Reform Committee of the British Medical Association, and when any question of medical reform has been before Parliament, I, in combination with others, have striven to the utmost of our power and ability to secure adequate penal clauses under this head.

2. I am. I am in favour of the exercise by the Council of any power or authority of this kind that it possesses, but seeing that the Council is only the *exponent*, not the *maker*, of the Acts of Parliament it is set to administer, and that it does not possess any such power, except in an indirect manner, against such qualified practitioners as depute to unqualified assistants who have no licence to practise (and against whom I would use every available power), I do not see how much in this direction can be expected of any representatives. As I have said in paragraph 12 of my address, "I hold that the regulation of the organisation of the profession is the true work of the Council, whilst its protection against unqualified assailants is the duty of *Parliament;* but I none the less also hold that the Council should at all times be the chief adviser of the Government; and I would lose no opportunity that might ever arise to induce any Government to put a stop to illegal practice. Should it ever be in my power, as a member of the Council, to urge the necessity of protection of the qualified as against unqualified practitioners in any way upon Parliament, I would spare no effort either to do so or to make my voice heard.

3. No, I am not. I hold the licence of the Society myself, and for thirty-seven years have practised medicine on the strength of it, and to repudiate it now would be both mean and dishonest. I consider that the Society has been of great use and value in its day, and that it has done great things both for the cause of medical education and for the profession. I should be sorry to see the Society driven into existence as a separate and second portal of entrance into the profession, and I do not consider such course a necessity. My desire would be to see a righteous consolidation of the three now existing authorities—viz., the College of Physicians, the College of Surgeons, and the Apothecaries' Society—into one examining body, whose examinations, after proving a candidate to be satisfactorily qualified to practise medicine, surgery, midwifery, and pharmacy, should admit him to register as a "qualified general practitioner." By a second examination, before the same body but on higher lines, I would enable him to obtain a higher degree, say, his F.R.C.S., or, if he preferred a *medical* distinction, an M.D.; and then I am of opinion that foreign degrees would become so rare that, in union with a British qualification, and under proper guarantees, it might, in generosity, be admitted to simultaneous registration.

4. My last answer in a great measure covers this question. Rather than drive Englishmen to seek either foreign or Scotch or Irish M.D. degrees, I am; but I should much prefer the mode of granting such degree sketched above—i.e., as a higher qualification for an already registered general practitioner.

I am sorry my replies have run to so great a length, but I consider this letter a very serious one, and prefer their doing even that to leaving them in ambiguity.

I am, Gentlemen, yours very truly,

Messrs. Verdon and Bott. (Signed) C. G. WHEELHOUSE.

26, Manchester-square, W., Nov. 3rd, 1886.

DEAR SIRS,—I have pleasure in answering your questions in the order in which they come.

1. Yes.

2. Yes.

3. I do not think it [illegible] holders of its licence to abolish the Apothecaries' Company. But I think that the Company requires to be reformed, and that it may then play as important a part in the future of medicine as it has done in the past.

4. Yes. I am, dear Sirs, faithfully yours,

Messrs. Verdon and Bott. (Signed) B. W. RICHARDSON.

Horton House, Halifax, Nov. 2nd, 1886.

DEAR SIRS,—I enclose you copy of my address at Manchester; you will see my views clearly expressed:—

1. I am in favour of penal legislation and actions against unqualified practitioners.

2. I should, if returned, bring the subject before the Council.

3. If the Apothecaries' Society were suppressed, *our sole chance* of prosecution would be taken away. I should regard this as a calamity. As a licentiate of this Society, I should resist such a proposal.

4. As regards qualifications, I have always advocated the one-portal system; and now, with the absolute necessity of English students having a degree of M.D., support this Conjoint Scheme as far as it goes. I should like to see some retrospective legislation for the men now qualified, to obtain the degree of M.D. by examination or otherwise.

Yours very truly,

Messrs. Verdon and Bott. (Signed) T. M. DOLAN.

7, King William-street, E.C., Nov. 2nd, 1886.

DEAR SIRS,—In reply to your letter, to hand this evening, I beg to say—

1. That I am in favour of penal legislation directed against unqualified practitioners.

2. That I am strongly in favour of the General Medical Council protecting the profession against unqualified practice.

3. I am not in favour of the abolition of the Apothecaries' Society, unless under some comprehensive scheme amalgamating the various medical corporations, and then only if the penal clauses of the Apothecaries Act of 1815 are vested in some other body representing the profession.

4. I am in favour of granting a medical degree to all who pass a complete examination in medicine, surgery, and obstetrics. I am, dear Sirs, yours obediently,

Messrs. Verdon and Bott. (Signed) GEORGE BROWN.

130, Stockwell-road, S.W., Nov. 2nd, 1886.

DEAR SIRS, In reply to your questions just now received

1. I am in favour of such legislation as you name, but you will *not now get it.*

2. I am in favour of the protection you suggest *upon principle*, but practically it could not be carried out.

3. I am not in favour of the abolition of the Apothecaries Society. Nor is there the least fear that they will be abolished; on the contrary, they will, under the new Act, become a more powerful corporation than they now are.

4. I am not in favour of the *present scheme* of the conjoint Colleges for granting a Doctorate in Medicine.

I am, Gentlemen, faithfully yours,

Messrs. Verdon and Bott. (Signed) E. H. S. CARPENTER.

25, Highbury-place, Nov. 8th, 1886.

DEAR SIRS,—I am sorry that your letter got mislaid, and that I could not find it till now (midnight). My answer to the questions you propose is as follows:—

1. I am in favour of severe penal measures against all unqualified practitioners that pretend to be qualified, or in any way defraud the public.

2. I think the Council should be made responsible for prosecuting such cases, and would, in doing so, make good use of its accumulating funds.

3. I recognise in the New Act a new lease for the Apothecaries' Society, unless the other corporations incorporate it in their scheme, or by their action make it superfluous.

4. I am deeply alive to the necessity of creating facilities in London for medical graduation such as exist in Scotland. There should be established for this end a *teaching* university in London such as exists in *every other metropolis in Europe.* To give examining corporations a degree-granting power may become necessary, but this is not the scheme that would meet the competition of regular universities in other parts, nor one that seems to me the best.

Again apologising for my delay,

I am, Gentlemen, your obedient servant,

Messrs. Verdon and Bott. (Signed) JAMES GREY GLOVER.

To the Editor of THE LANCET.

SIR,—In spite of your warning in THE LANCET (Oct. 2nd), which should not have been needed by a body of English gentlemen, the Council of the British Medical Association have passed a resolution in favour of *two of themselves*, and this resolution is being used to produce the erroneous impression that the two councillors have been nominated by the Association. So successful have been the misrepresentations made, that not only members, but even officers of the branches, have expressed their regret that the Association required their allegiance, or their annoyance at the pressure put on them. I went to Brighton expressly to see whether the Association wished to take part in the election, and was prepared, as another candidate said he was, to submit my views to the consideration of my fellow-members, or any committee they might appoint; but the general meeting refused to take any part in the election, and although the Council managed to get the question brought up at two separate meetings, the members would not, on either occasion, forego their independence or refer the subject to their Council.

Your columns have recorded how, after this, certain of these councillors held a private meeting in their hotel, developed into the Birmingham 32, who, after dwindling to 14 or 15, took a vote by 11 to 3. To say the least, candidates who were not consulted can scarcely be expected to regard these 11 ayes as representing the profession; while, as to the Association, they were not only without its mandate, but acting in direct opposition to its decision. It has been asserted that this "committee was formed under conditions involving the greatest publicity; for it was projected at an annual meeting of the Association, which was of the most public character." (!) This misstatement was at once flatly contradicted by Mr. Armstrong and others of your correspondents, and is completely at variance with the statements of Dr. Carter himself in your last issue. But my correspondence convinces me that it is still necessary to repeat that the committee was not formed until after the Association, in general meeting assembled, had refused to interfere in the election, after the proposal to refer the matter to the Council had been rejected amidst overwhelming expressions of dissent. We have since been told that the proposal to refer the matter to the Council "was brought forward at a time and under circumstances which made it impossible even fairly to discuss it." This, also, is a complete misrepresentation. The proposal was brought forward on two separate days, and, in spite of all the pressure that could be exercised, the members on both occasions declined to intervene. I should have supposed that no one actually present could have been deceived as to the determination of the members; but in THE LANCET of Oct. 30th Dr. Carter says his "own idea" is, that if a vote could have been taken at the "very large meeting" his proposal "would have been adopted with very few dissentients." But neither the candidates nor the other councillors laboured under such a mistake. As was remarked by more than one of the audience, "they dropped the proposal like a hot potato," and if they or Dr. Carter had stayed to listen to the denunciations which were afterwards freely expressed, there might possibly have been less need for subsequent protests. Both the meetings refused to support the gentlemen brought forward by Dr. Carter, and therefore they have no right to pose as the nominees of the Association, but only of the committee formed at their hotel by those who refused to accept the decision of the general meeting. After they had gathered their 300 they called themselves a "committee for ascertaining the wishes of the profession"; but on their own showing the utmost they did by the post-card poll of themselves was to ascertain their own wishes. They have since refused to publish the numbers of that poll, or give any information about it, so that there is much point in Mr. Hardy's remark, that we are asked to accept the decision of three persons as the voice of the profession. Nevertheless, Dr. Carter advertises in THE LANCET that his candidates were "selected" by his committee "*after an open vote!*" Dr. Glover declined the coalition so astutely "projected" for him, but his name is being used as if he had accepted it. If Messrs. Wheelhouse and Foster succeed in keeping up the delusion that they are the nominees of the Association, and thereby secure their election, they will be welcome to a victory obtained by such means.

I am, Sir, yours faithfully,

Nov. 3rd, 1886. M. PROSSER JAMES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of to-day Dr. Henry W. Williams makes some statements that are not quite accurate. He says that the Brighton meeting "distinctly declined to take any part in the selection of candidates." No doubt this is his recollection of what took place at the meeting, but it is not the published record of the proceedings taken from the shorthand writers' notes (*vide British Medical Journal*, Aug. 14th, 1886, p. 336), nor is it my recollection of what occurred. The fact is that the meeting expressed no opinion whatever, for the very good reason that no vote was taken, and, as the record of the proceedings states, "the matter dropped." It did so because the resolution and the amendment were both withdrawn. Dr. Carter's resolution was as follows: "That it be an instruction from this meeting to the Council of the British Medical Association to select three names of gentlemen suitable for election to the General Medical Council by the medical practitioners of England, and to submit them to a future general meeting during the session of the Association in Brighton." Dr. Dolan moved the following amendment: "That inasmuch as it is inexpedient that this Association should appear in any way to interfere with the discretion of the profession at large to elect their direct representatives, the action of the Association ought to be strictly limited to obtaining from such of its members as desire to express their opinion a plebiscite upon the names of those candidates for the office who may submit their names for the purpose through the Council." Dr. Bernard O'Connor, another candidate, moved "that no action be taken in the matter," but this amendment was not even seconded, and Dr. Carter and Dr. Dolan having withdrawn their motions, the matter dropped and the meeting separated. This is the simple statement of what took place, and does not justify the construction advanced by Dr. Williams, nor in any way support the conclusion that Mr. Wheelhouse and Sir B. W. Foster are "acting in opposition to the expressed will of the general meeting." I hope he will therefore withdraw a statement which is unfair. In conclusion, I wish to point out that my committee have acted upon the very lines laid down in Dr. Dolan's amendment, and that the credit of our method of a plebiscite to select our candidates is due to him.

I am, Sir, yours truly,

Halesowen, Nov. 6th, 1886. HUGH R. KER.

To the Editor of THE LANCET.

SIR,—The letter of Dr. Joseph Rogers, which was inserted in your issue of the 30th ult., has had the effect of misleading many Poor-law medical officers, as it has since been re-printed in an isolated form and very generally circulated from Birmingham (as indicated by the post marks), with an appendage to Dr. Rogers' signature, which was not in your publication. I am sure Dr. Rogers never wished this letter to appear as if written by him in an official capacity—viz., as Chairman of the Poor-law Medical Officers' Association, and I believe he now regrets that he has given an opportunity for this construction to be put upon it. He has since signed my nomination paper, and thereby recommended me as a fit candidate for election to the Medical Council. I am, Sir, your obedient servant,

Royston, Nov. 9th, 1886. D. B. BALDING.

To the Editor of THE LANCET.

SIR,—I feel it to be a duty to explain to my professional brethren, and especially to Poor-law medical officers, that a letter in reference to direct representation on the General Medical Council, which is now being extensively circulated, and bears the signature of Dr. Joseph Rogers, and may by many be supposed to emanate from the Poor-law Medical Officers' Association, has not been sanctioned by that body or its Council, but must be regarded as one from Dr. Rogers himself, and for which the Association or its Council takes no responsibility.—I am, Sir, yours truly,

JAMES CORNWALL, F.R.C.S. Eng.,
Senior Vice-President Medical Officers' Association.
Fairford.

DR. GLOVER AND FREEDOM OF ELECTION.

To the Editor of THE LANCET.

SIR,—It having just been brought to my notice by Sir Crichton Browne, the chairman of Dr. Richardson's committee, that there is an impression with some that Dr. Glover has attempted to influence the other two votes of his supporters, I have the authority of Dr. Glover to state that he has on no occasion attempted, directly or indirectly, to do so, and he begs me further to take this opportunity to inform his friends that he desires them to feel themselves perfectly free as regards the disposal of their other two votes. I am, Sir, yours truly,

HENRY J. STOKES, M.D.,
Chairman of Dr. Glover's Committee.

Compton-terrace, Highbury, N., Nov. 10th, 1886.

THE GENERAL MEETING AT THE COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—In reference to your comment that my speech lost much of its force owing to its being too long, and to the persistency with which I disregarded the evident impatience of the audience, may I be allowed a few words of explanation? My speech was calculated to last not more than twenty minutes, but owing to the interpolation of remarks in reply to Mr. Erichsen, whom I had been asked to follow, and to my not having taken the precaution to look at the clock when I rose, time was expended without my being at all aware of its amount. When, for the first time during my speech, I was interrupted, it was by the President concerning the Apothecaries' Society. The remarks which then remained would have occupied without further interruption precisely two minutes; and as the President's admonition had not been cheered by the audience, and as without a dissentient voice he requested me to proceed, I was naturally led to suppose that the meeting was quite ready to hear me out, and that the barometer did not indicate any sudden fall within that brief space of time. A minute later, which probably seemed longer in the close atmosphere of the place, I was checked, for a moment only, by a noise from the antipodes of the theatre. I proceeded with what I plainly stated was my last point, and was within sight of the winning-post, when the still distant and not at all intelligible noise broke out again. As I was in the middle of a sentence and had only three sentences more to deliver, embodying, as I thought, an important argument, and absolutely necessary to complete the sense of the passage, I felt justified in making an effort to outlive the jarring elements, which I did not recognise by any means as the sense of the meeting generally; but, the President intervening, I thought it would be ludicrous to have my unheard and unknown peroration put to the vote, unless he would read it to the malcontents, and therefore I resumed my seat. I now ask leave to quote the amputated sentences:—"You are approached by your professional brethren, who ask that their representatives may sit with you at the Council board. If you turn a deaf ear to that claim, if you say the bulk of the profession is not worthy of any such privilege, and your opinion is known in the high places of the land, what effect on the social standing of the profession must such a refusal have? The public will estimate the rank and file of the profession at the value placed on them by their acknowledged leaders, and, therefore, on the decision of this question by the Council rests the elevation or depression of the profession in the social scale." Ever since my medico-political education commenced with the perusal of reforming articles in THE LANCET I have taken a deep interest in questions relating to the representation of the profession in the Medical Council and the Corporations. The former I advocated twenty years ago, and both were advocated in my Carmichael Essay, and in my oration at the Hunterian Society in 1879. From long standing conviction, therefore, and from a sense of what is due to the Members of the College and to the profession at large, I have come forward again (and, as I am informed and believe, in opposition to my private interests) to aid a righteous and most important cause. Under these circumstances I hope I may [illegible] error will be condoned, and I [illegible] accidental trespass, I excluded any more efficient champion, or unwittingly exhausted the patience of a few of those whom I intended to serve. I am, Sir, yours, &c.,

Nov. 8th, 1886. WALTER RIVINGTON.

To the Editor of THE LANCET.

SIR,—May we crave a fraction of space in your journal for a brief explanation of the amendment proposed and seconded by us at the General Meeting of the College of Surgeons on the 4th inst.? That meeting had already so far exceeded in its duration those of last year that Members of the College, drawn by the calls of busy practice, had for the most part left the theatre, and we therefore could not try the patience of those remaining by a lengthy exposition. The amendment suggested by us was that, in Mr. Paul Swain's resolution bearing upon the widening of the basis of the Fellowship, the word "first" be inserted before the word "method." This, the fourth resolution, thus amended, was subsequently carried as a substantive motion. Now for its effect. It is that the Council is apprised of the views of the Members—to wit, that they do not wish to obtain a Fellowship granted annually by election to ten Members of twenty years' standing; while they acknowledge with gratitude the concession made by the Council in exempting Members of fifteen years' standing from the ordeal of the Primary Examination in Anatomy and Physiology. The Members of the College are not hankering after a final decoration, as they do not desire the empty glory of a Fellowship acquired by an act of grace, or by nomination; an evil that originated, though in enormously greater proportion, at the time of the first creation of the Fellowship, and which they had hoped would die out with the natural term of life of the Fellows then fathered upon the College. The Members do not call for any change derogatory to the academic status of a distinction now most honourable in that it is acquired by examination. On the other hand, in the second of the two methods adopted by the Council, they perceive a wise attempt to meet the wants of a *few*. Members who have acquired superior skill in surgery and pathology, and who, while not sufficiently numerous to cause any anxiety to the exclusive character of the Fellowship, would yet be no mean compeers of men whose circumstances in early life have permitted them to enter at the usual epoch in their professional career the list of candidates for that honour. The Members recognise with thankfulness the consideration of the Council, herein shown, for those whose practical skill, as evinced by their passing the searching tests of the Second Examination for the Fellowship, should excuse them from the technical drudgery of undergoing a fresh training in the latest editions of the alphabet of their art.

We consider the first proposal of the Council, together with its late position in relation to the Society of Apothecaries, as fresh proof, if proof were needed, that without a few Members of the College of Surgeons sitting upon the College Council, that body, with howsoever goodwill, can never effectually keep touch with the majority of its diplomates. At present, though the Members would gladly work *with* the Council, they are forced by that body to act *outside* it; and the petition, a copy of which appeared on page 43 (advertisement) of your issue of Oct. 16th, will show in what direction their efforts must tend. At the risk of monotony, we still ask for further signatures, in order that our hands may be strengthened to the utmost in an undertaking the success of which appears to be almost within our grasp.—We are, Sir, your obedient servants,

WARWICK C. STEELE,
WM. ASHTON ELLIS,
Hon. Secs., Association of Members of Royal College of Surgeons, England.

Nov. 8th, 1886.

THE ENGLISH CONJOINT BOARD.

To the Editor of THE LANCET.

SIR,—On behalf of myself and colleagues, I beg to call your attention to the effect of the new regulations of the Examining Board in England on the recognised provincial hospitals.

By the present arrangement of the two Colleges, neither will give its qualification separately, and therefore the regulations issued by them conjointly must be obeyed by all those wishing to obtain the diploma of L.R.C.P. or M.R.C.S.

Prior to this combination a student commencing his studies at one of the recognised provincial hospitals was allowed to count a year's hospital practice as one of the four years of study required to obtain his diploma—i.e., a student having spent his first year at a recognised provincial hospital entered at a medical school, and at the end of his second winter session at such school could present himself for his Primary College, now called the Second Examination. A year subsequently he was allowed to present himself for the Final, in virtue of having spent a year at a recognised provincial hospital. By the present arrangement, he is not permitted to present himself for his Final until *two years* after passing his Second Examination, and thus the student who did a year's practical work before entering a medical school is, as far as time goes, no better off than his fellow who came straight to such medical school without any previous training; in fact, the provincial hospital student has lost a year. It may be suggested that men can come into the country after their second year in London, but this would not take place for the following reason. By going into the country at that time, they would lose all position at their school as third-year's students, and consequently all chance of obtaining valuable appointments for which otherwise they would be eligible. Thus the large amount of valuable experience and practice obtainable at the provincial hospitals are lost to future students, whilst the loss of a working staff of students to such hospital itself is a very serious one. I would suggest that all candidates for election to the Medical Council be asked to give their support, in order to get the state of things complained of altered.

I am, Sir, yours truly,

JAS. BANKART,

Senior Surgeon to the Devon and Exeter Hospital.

Exeter, Nov. 9th, 1886.

*** Under the present arrangement, instruction in Chemistry, Practical Chemistry, Materia Medica, and Pharmacy may be given before the student's entry at a recognised medical school, in the first year of medical study after registration, and the student can spend his time during this period at no better place than at a provincial hospital. He can pass his final examinations in three years and a half after entering a medical school, and few students have ever obtained the diplomas of M.R.C.S. and L.R.C.P. in less time than this under the old regulations.—ED. L.

THE QUEEN'S JUBILEE: A SUGGESTION.

To the Editor of THE LANCET.

SIR,—I not infrequently hear it asked, "How is the medical profession going to commemorate the Queen's Jubilee?" Would you grant me space to make one suggestion? There is one medical corporation—the Royal College of Surgeons of England—that stands greatly in need of a "Hall," a building commensurate with the present position of the College, where Members and Fellows may hold their meetings; in which all collegiate entertainments might be given, rather than in the library and museum as at present; in which all the works of art might be placed. Nothing can be less fitting than the present position of the busts—a collection *nulli secundus*. The pictures as works of art, with a few exceptions, are not great; but they represent great men, and should be placed where all members of the corporation might have an opportunity of seeing them. The College is greatly indebted to the Queen for the gracious interest Her Majesty took in the new building on the Embankment, and it might be called the "Queen's Hall," and contain a statue of Her Majesty. It would also serve as an expression of the appreciation of the College of the great bequest we are about to receive. There would be little difficulty in finding within the precincts of the College the necessary space. I trust I may be pardoned for thus intruding myself on so important an occasion. It is singular that the position of the new Examination Hall in the Savoy is one of those suggested to Dr. William Hunter, when, in 1764, previous to building his school in Great Windmill-street, he offered the Government to build a school and museum at his own cost if he were granted the ground. This offer was refused, and that magnificent collection he brought together is in Glasgow.

I am, Sir, your obedient servant,

Athenæum Club, Nov. 9th, 1886. CHARLES HAWKINS.

"DEATH OF A PASTEUR PATIENT UNDER SUSPICIOUS CIRCUMSTANCES."

To the Editor of THE LANCET.

SIR,—A paragraph with the above sensational heading appeared in a number of newspapers in this district last Thursday, the announcement being slightly varied in some of them. The deceased, A. Wilde, was stated to have been bitten by an unfortunate man named Oates, who died of rabies at Rotherham some weeks ago, and whom he was assisting to nurse. Wilde subsequently went to Paris and was treated by Pasteur. Considering the serious character of the case, involving a possible (and probable) charge of failure against Pasteur's method, if not the conclusion being drawn that the treatment itself was the cause of death, I went at once to Rotherham, my object being to obtain some material from the deceased for test-inoculations to prove whether any, and what kind, of rabic virus was present. There is no difficulty in distinguishing whether the virus in such a case has emanated from a dog (even after passing through a human subject) or from the rabbit (which is the virus used by Pasteur). On arriving at Rotherham, I was not a little surprised to find that nothing was known about the startling news, and that no "suspicious circumstances" had occurred: in fact, it was evident that the thing was a cruel and improper *canard*. Dr. Foote, the medical attendant, told me the cause of death was acute congestion of the lungs, and that there had never been a symptom simulating rabes. Dr. Waller, who made the post-mortem examination, informed me that all the appearances were quite in consonance with the symptoms seen during life, and that there was absolutely nothing to support the sensational newspaper report. I accordingly felt it would be quite useless and unnecessary to make any inoculations, as the cause of death was clear. The reprehensible manufacture of such *canards* cannot be too strongly condemned.

I am, Sir, your obedient servant,

Bradford, Nov. 9th, 1886. THOS. WHITESIDE HIME.

P.S.—I may add that Wilde was not really intentionally bitten by the deceased, Oates. But in a struggle while trying to get that unfortunate man into bed he suffered an abrasion of the skin, quite justifying the anxiety which caused him to be sent to Pasteur for treatment.

INDUCTION OF LABOUR IN CASES OF ALBUMINURIA IN PREGNANCY.

To the Editor of THE LANCET.

SIR,—The letters from Dr. Donald and Dr. Cullingworth (Nov. 6th) satisfactorily dispose of the doubts expressed by Dr. Murphy and myself relative to the potency of the drugs, pilocarpine and jaborandi, used in the case recorded Sept. 18th. They prove that these two drugs are not infallible diaphoretics. They also lend support to the view that when sweating is produced and good done, it is probably the sweating rather than any specific action of the drug which does the good, for in this case no good was done and no sweating was produced. If Dr. Donald will read my letter again, he will see that I did not say that if the drug produces marked diaphoresis then good will follow. I think it very likely that cases may occur in which the pilocarpine causes the usual copious perspirations, without having any beneficial effect in cases like that of Dr. Cullingworth, or even in cases of puerperal convulsions. But believing that pilocarpine does good because of its diaphoretic properties, and not because of any of its other physiological effects, I am not surprised to find that in this case, in which, for some reason or other, no sweating was caused, no benefit resulted. Indeed, hot-air baths were tried without benefit, and it is not stated whether they produced sweating or not, but it is stated further on that the skin was very dry. With regard to the ecbolic action of pilocarpine, Massman of St. Petersburg appears to have accidentally found it out (*vide* THE LANCET, Feb. 8th, 1879) while using the drug in a case of pregnancy with dropsy. In my first case of puerperal eclampsia in which pilocarpine was used I did not pay attention to this point, but from subsequent experience I feel sure it was the pilocarpine which caused the death of the child by setting up tetanic uterine contraction. In my second case the [illegible] were quite remarkable after the use of

evidence lies quite on the other side, and refers to researches by Hyernaux and cases by Clay and Kleinwachter. On referring to these (*Lond. Med. Record*, Jan. 1879), I find that Hyernaux administered hypodermic injections of pilocarpine to two pregnant women. In the first case labour resulted, but enemata and vaginal injections and hip baths had been employed as well. In the second case labour was not induced, although sweating was caused. In Clay's case pilocarpine caused uterine contractions until the os was the size of a halfpenny, and labour pains were present at intervals of fifteen minutes. In Kleinwachter's case three injections of pilocarpine were given to induce labour. Uterine contractions set in an hour and a half after the first injection. An hour and a half after the second injection the membranes burst, but the pains went off during the night. After a third injection the pains again commenced. I submit that these cases of Clay and Kleinwachter afford positive evidence of the ecbolic action of pilocarpine. No doubt if the drug be given at long enough intervals the action may not be great; but if given at short intervals it will in most cases cause uterine contractions; but these are so prolonged that it is not desirable to employ pilocarpine for the induction of labour.

I am, Sir, yours truly,

St. Thomas's-street, S.E., Nov. 9th, 1886. P. HORROCKS.

To the Editor of THE LANCET.

SIR,—The experiments of Dr. Donald with the pilocarpine used in Dr. Cullingworth's case are very interesting, and dispose of the assumption that it was altogether inert; but that does not at the same time dispose of my contention, that the trial was not a satisfactory one, inasmuch as the characteristic diaphoresis did not take place. Now, from what we know of pilocarpine, it may be safely stated this was owing to causes either extrinsic or intrinsic to the patient; if the former, it does not concern me; if the latter, the failure was due to some cause peculiar to the patient as an individual, or to some feature of the disease. If due to an idiosyncrasy, we need not further discuss it; but if from his experience of this one case Dr. Cullingworth contends that there is a type of the albuminuria of pregnancy in which pilocarpine properly administered in full doses does not produce diaphoresis, I may, I think, in perfect fairness, ask him to admit that in this peculiar type, as far as he knows, convulsions never occur, and the termination is always favourable. I am, Sir, yours &c.,

Sunderland, Nov. 9th, 1886. JAMES MURPHY.

INFANT MORTALITY IN READING.

To the Editor of THE LANCET.

SIR,—Dr. Shea, medical officer of health for Reading, shifts the question of infant mortality in the borough, which was the subject brought by me before the Pathological Society for discussion, to that of the "vital statistics of Reading." He complains that I compare the thickly populated borough of Reading with the sparsely populated rural districts adjoining; and thus implies that the comparison is unfair to the borough, as these have a "greater area in acres." Density of population is not necessarily associated with as high a death-rate as that of Reading. For example, West Ham, in Essex, has a population of more than 150,000—i.e., nearly four times the population of Reading—and the same population to the acre as Reading; yet its death-rate is not so high this town. Other comparisons might be made not favourable to Reading; but this was not the object of my communication to the Pathological Society. The Registrar-General states that "healthy districts are all those registration districts in which the mean annual death-rate for persons (males and females together) was under 17·00 per 1000 in 1871-80." Reading during this period had a death-rate of 19·00, or, excluding the deaths in the Royal Berks Hospital, 18·00, so that the registration district of the borough of Reading is excluded from the Registrar-General's list of healthy districts. No one is more competent, by his knowledge and earnestness in the work, to effect a permanent reduction in the death-rate of Reading than Dr. Shea. But the period embraced by his statistics is too brief to bear comparison with that of the Registrar-General.

I am, Sir, yours obediently,

Nov. 10th, 1886. [illegible] BARFORD.

INFANTILE DIARRHŒA.

To the Editor of THE LANCET.

SIR,—Your annotation on the above-named disease (?) in THE LANCET of Sept. 18th serves to awaken memories of the past. My interest in the subject began with my advent in Leicester at the end of 1876, and terminated with the meeting of medical officers of health at York on April 7th, 1881. To this meeting, which was specially convened to discuss Infantile Mortality from Diarrhœa, I was invited as one who had put on record his observations of the complaint in question both at Leicester and Nottingham. Drs. Ballard and Parsons represented the Local Government Board, and an interesting and instructive discussion ended with Dr. Ballard's announcement of his Commission of Inquiry into the causes of summer diarrhœa. Dr. Ballard had the honour of closing the debate in a speech, from which I extract the following:—"He had been at a great deal of trouble to cleanse, and sweep, and brush, and scour his mind from everything in the shape of a preconceived notion either as to what diarrhœa is or what its cause or causes." After such a declaration considerable expectations were naturally raised, and all present appeared inclined to yield the palm to a gentleman of such impartial views, and to await his promised report. Of that report I have never since heard, and my chief object in writing is to ask if any such report has been published. From the tone and wording of the annotation referred to, no progress appears to have been made since 1881, and therefore I assume that no such report has been issued from the central department of public health. It occurred to me at the York meeting that Dr. Ballard was too free in his use of the "broom," for there had been some very searching inquiries (both official and non-official) going on for several years at Leicester—where the disease is endemic—and elsewhere, my own line of inquiry being conducted in the following order: 1. What is the average quarterly and annual birth-rate of the given town or district in question, and what proportion does the infant population bear to the general population? 2. What are the habits and employment of the parents, and their physical and moral status? 3. What are the direct effects of heat on the human economy, and particularly on infants? 4. Will heat *per se* produce diarrhœa, irrespective of sanitary condition, and will insanitary conditions aggravate the disease when heat is present? 5. What increment of heat is necessary to produce epidemic diarrhœa? 6. Is summer diarrhœa a mild form of cholera, and are the Americans justified in calling it "cholera infantum"? 7. Is infantile summer diarrhœa a zymotic or a constitutional disease?

My actual experience of summer diarrhœa at Leicester and Nottingham, which has been published in detail, together with a review of the sanitary history of the former town extending over a period of thirty years, enabled me to arrive at certain definite conclusions which have never been traversed, and which time (the great avenger) has verified. For these and for kindred observations on infant mortality I have never received the shadow of acknowledgment from the medical press of this country. It is not so abroad; our French neighbours can and do appreciate voluntary effort in the cause of science and of humanity; but in England it appears to be necessary first to die in order to live! Do we not see it illustrated every day, and notably at present in your influential columns?

I am, Sir, your obedient servant,

ALEXANDER MCCOOK WEIR, M.D., &c.

Nottingham, Sept. 1886.

SOCIETY FOR THE PREVENTION OF HYDROPHOBIA AND REFORM OF THE DOG LAWS.—The General Committee of this Society held its fourth meeting on Friday last at the offices, 50, Leicester-square, London, W.C., to consider a programme which had been drafted by the Sub-committee and circulated among members and supporters. Mr. Victor Horsley, F.R.S., was elected a member of committee. Many letters were read expressing approval of the programme, and regretting that the writers were unable to attend. The Honorary Secretary having made a financial statement of a satisfactory nature, the Chairman, Colonel R. H. Rosser, briefly explained the care and time given by the Sub-committee to the programme, which was then discussed in detail, and ordered to be printed with some additions and alterations.

MANCHESTER.

(From our own Correspondent.)

THE PREVALENCE OF SCARLET FEVER.

The weekly returns of our medical officers of health have for some weeks past shown the greatly increased prevalence in Manchester and Salford of scarlet fever, more than a thousand cases having been notified during the last quarter, and at the monthly meeting of the Board of the Royal Infirmary it was stated that there were upwards of 200 cases of the disease under treatment in the fever hospital belonging to that institution. From returns published in other towns, it would almost seem as if an epidemic scarlet fever wave were passing over the country, as Liverpool, Dundee, Leeds, Aberdeen, Oldham, &c., all show a considerable increase of late of scarlet fever. At the last meeting of the Openshaw Local Board the propriety of taking steps to get the cases in that district reported by the medical practitioners was discussed.

THE MANCHESTER AND SALFORD SANITARY ASSOCIATION

at times act as a thorn in the side of our sanitary authorities. They have been drawing the attention of the latter to the need for increased supervision and inspection of our bakehouses. They have also been considering what steps can be taken for the better safe-guarding of the sources of our milk-supply, and have forwarded a memorial to the Privy Council asking for the inclusion of anthrax or splenic fever amongst the other contagious diseases in the Act relating to the same, as there has been recently loss of human life from this disease being transmitted from cattle to man. The necessary order has since been issued by the Privy Council.

THE VICTORIA UNIVERSITY.

"Degree day" was held on the 4th inst., and the ceremony took place in the Town-hall, instead of, as usual, in the College. There was a large attendance both of the general public and those taking part in the proceedings. Amongst the latter were the Bishop of Chester and Sir U. Kay-Shuttleworth, M.P. It was noteworthy as being the first occasion on which a doctor's degree has been conferred, and this was in the faculty of medicine. The gentleman who has gained this distinction is Mr. E. Gordon. In the afternoon of the same day, at a meeting of the University Court, Dr. Banks, of University College, Liverpool, was elected as the representative of the University in the General Medical Council. At the same meeting it was resolved to again apply to Government for a grant towards the expenses of the University, as the finances at present are not in a satisfactory condition.

HOSPITAL SUNDAY AND SATURDAY.

Yesterday, at the annual meeting for distributing the sums received at Hospital Sunday and Saturday collections, it was announced that the total received this year was only £7640, being £520 less than in 1885. Of this sum the Royal Infirmary gets £2850. It was urged that more support might fairly be asked from the surrounding towns, seeing how large a number of patients they send annually to our various medical charities.

DEATH FROM CHLOROFORM.

Another death from chloroform occurred on the 5th inst. at the Manchester Workhouse Infirmary. The patient, a man aged thirty-six, was being placed under chloroform, but before complete anæsthesia was induced or the operation commenced, he suddenly ceased breathing. At the necropsy no abnormal condition of the organs was discovered to account for the fatal result.

THE LOCAL MEDICAL SOCIETIES.

The Pathological Society, one of our last formed, is in a very satisfactory condition; its meetings are well attended, and it now counts nearly 100 members. Dr. Dreschfeld has been elected President for the present year. The Central Medical Society, which was established to a certain extent in opposition to the Medical Society of the College, is by no means behind the others, and appears full of life and vigour. Mr. F. H. Walmsley is President, and Drs. L. Jones and Woodcock Vice-Presidents, for the currrent year.

A GENEROUS BEQUEST.

The Royal Infirmary has received £1000 under the will of the late Mr. H. Boddington. This charity has not had of late any very large legacies. There will shortly be placed within its walls busts of three of its former eminent surgeons—viz., C. White, Joseph Jordan, and Thos. Turner.

Manchester, Nov. 9th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE INFIRMARY.

The unsatisfactory state of the finances of the Newcastle Infirmary has been the subject of much comment and controversy in our local papers. Some of the writers would appear to be possessed of a spirit the reverse of friendly to this noble and beneficent institution. There can be no doubt, however, that some reforms in the management are called for, and indeed are urgent, before the public, and especially the artisan classes, can be expected to take their share of the burden of supporting the hospital. I give you a few figures which will show at a glance the work done, and the cause of its present embarrassment. The number of patients in the infirmary at the present time is 280. During the past year the number of in-patients was 2846, out-patients 4932, and casuals 27,811. The average cost of in-patients was £4 7*s.* 10½*d.*, and of each out-patient and casual 10½*d.* The receipts last year were £10,437, and the expenditure £13,947; but it is shown that if the infirmary is to go on at the rate of the last few years, there will be a deficiency annually of something like £7000, and that the funded property of the institution, already much trenched upon, will soon become exhausted. At a court of governors held last week, and presided over by the Earl of Ravensworth, the matter came up for consideration; but there is a feeling that there was rather too much set speech-making and too little free discussion. There were, however, some good and practical suggestions made. At first a motion was proposed to limit the in-patients to 200, and to make a proportionate reduction in the nursing staff, &c.; but this was not carried, the feeling being strongly against any curtailmeut of the work of the hospital, and as strongly in favour of increasing its income. Mr. R. H. Holmes, hon. sec. to our Hospital Sunday Fund, seemed in his few remarks to have a complete grasp of the financial difficulty and of the way out of this labyrinth. For instance, he showed that a systematic weekly collection of one penny over the year would produce £2400, and of another large company £4000 per annum. Besides giving the men a more direct interest in work and support of the infirmary, Mr. Holmes' plan has much to recommend it, and little or nothing can be said against it. As the success of the system has been already proved in Sunderland, Leeds, and other large towns, a special committee was appointed to confer with the house committee on the subject, and to report to the Governors.

A WOODEN-LEGGED COW.

Some eighteen months ago Mr. John Sharry, V.S., of Norton Malton, successfully amputated one of the hind legs for injury of a valuable and well-bred shorthorn cow, the object being to retain the cow for breeding purposes, while a wooden leg was affixed to the stump. Many will be pleased to hear that the object has been fully achieved; the cow is now a mother, and has a fine bull-calf running by her side.

A CHEAP "MODE" OF PROVIDING FOR MEDICAL SERVICE.

Dr. J. C. Murray, now of Stranraer, N.B., but formerly an active practitioner in Newcastle, has been writing some racy notes from his life and experience, from which I extract the following: "I remember a hypochondriacal biped or nervous patient who used to hang about my neighbourhood for hours. There were doctors passing it every ten minutes, and a chemist's shop above and below. At last, when a stout, slow-walking doctor walked up in the direction of his home, he would follow him, and wait near each house he went into until he got to his home. Our friend's windows had command of the foot or outlet of five streets. From these he used to [illegible] as he came down one and

went up another until he went home to dinner, when our hypochondriac, feeling he had done his best by viewing or being near a medical man as long as possible in case of sudden seizure of agglomerated sickness, would then take his dinner and a smoke, and feel he had done a good day's duty."

MEDICAL STUDENTS' DINNER.

The Newcastle students held their annual dinner on last Wednesday at the County Hotel in this city. Nearly 100 students were present. Dr. Arnison presided, while the vice-chair was occupied by Mr. H. E. Armstrong, our medical officer of health. The proceedings were very harmonious, and the dinner, upon the whole, is said to have been one of the happiest and most social that has ever been held in the history of the college.

ALNWICK INFIRMARY.

At the late annual meeting of the Alnwick Infirmary, Earl Percy in the chair, it was stated that the number of patients in and out of the house had numbered 862, of whom 789 had been cured or relieved, 39 had died, and 34 remained on the books. The statement as to the financial state of the hospital was considered satisfactory as compared with last year. At the same meeting it was resolved that Dr. Wilson, who had sent in his resignation as honorary physician, be asked to reconsider his resignation.

Newcastle-on-Tyne, Nov. 9th.

EDINBURGH.

(From our own Correspondent.)

THE SECRETARY FOR SCOTLAND IN EDINBURGH.

On the 30th ult., the Right Hon. A. J. Balfour, Secretary for Scotland, delivered an address, under the auspices of the Edinburgh School Board, to a large audience of the citizens. Eschewing most carefully all matters of party interest, Mr. Balfour discussed very fully the relations of primary and secondary education as at present constituted in Scotland, and took occasion to urge very forcibly the somewhat neglected claims of the latter, and to demand on its behalf a wider measure of individual and national support. In a few piquant apothegms he depicted the outcome of the present hiatus between primary and university education, and showed how deleteriously this lack of continuity acted upon the educational powers of the latter, by greatly reducing the range of their activity, and debarring them from the attainment of the highest possible practical results. Speaking of university reform, the right honourable gentleman confidently looked forward to the passing of the Bill which his predecessors have failed to push through the press of Parliamentary business. Of the provisions of the proposed Bill he did not speak more definitely than to infer that the measure as a whole might be termed "heroic"; but in dealing with another part of his subject, he expressed the view that there should be greatly increased facilities for the teaching of special branches of knowledge within the universities, and that the chairs so established should be liberally endowed, and the universities in this way should have their character raised from that of training schools for the professions to that of "seats of learning where the torch of human knowledge may be advanced." Mr. Balfour's visit to Edinburgh was primarily for the purpose of opening a Board school and addressing those interested in educational matters; but it is whispered that preliminary discussions with those most closely interested will take place, and that he will leave Edinburgh with the outline of the coming Universities (Scotland) Bill in his pocket.

THE ELECTION OF LORD RECTOR

resulted in the return of Lord Iddesleigh for a second term of office, which he is entitled to hold for the next three years. The Conservative candidate obtained the substantial majority of 347 votes over Sir Lyon Playfair, his Liberal opponent. There is no doubt, however, that this cannot be counted a party victory, for many other considerations besides party sentiment were at work in influencing the decision of the students.

ROYAL INFIRMARY.

A vacancy has occurred on the staff of surgeons attached to the infirmary, owing to the retirement of Mr. Joseph Bell. Each member of the present staff has been thus promoted one step, and in consequence an assistant-surgeonship has now to be filled up. Amongst the candidates already in the field are Dr. Hodsdon, assistant-physician to the Edinburgh Royal Hospital for Sick Children; Mr. Macdonald Brown, lecturer on anatomy in the Royal College of Surgeons; and Mr. A. W. Hare, senior demonstrator of surgery in the University. It is expected that other candidates will yet be forthcoming as the date of the election approaches.

Edinburgh, Nov. 9th.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

A MEMBER of the Senate will be elected next month, and already there are four candidates in the field for the vacancy —Mr. T. P. O'Connor, M.P., Dr. McMordie of Belfast, who was defeated on the last occasion, Major FitzGerald of Dublin, and Professor Stephen O'Sullivan, M.D., of Queen's College, Cork. The Graduates' Reform Association in Cork at a meeting appointed a deputation to wait upon the last-named gentleman, for the purpose of requesting him to withdraw his candidature in favour of Mr. O'Connor. The main object, it may be mentioned, of the Graduates' Reform Association is as stated by its president (Mr. O'Connor), to make the Senate and the Convocation of the University more representative of the mind and thought of the Irish nation. Professor O'Sullivan, however, decidedly refused to withdraw in favour even of the president of the Association. That this determination was only what might have been expected is shown from the following circumstances. Professor O'Sullivan, on October 15th, intimated to the members of Convocation of the Royal University his intention of becoming a candidate for the vacant seat on the Senate, while his opponent did not come forward until after the meeting of Convocation, which was held on the 27th ult. But leaving the priority of candidature out of the question, it is tolerably well known that the retirement of Professor O'Sullivan would not ensure Mr. O'Connor's success at the forthcoming election.

ACADEMY OF MEDICINE IN IRELAND.

The opening meeting of the Pathological Section of the Academy was held on the 5th inst., the presidential address being delivered by Dr. W. Smith. A rare specimen, that of a liver with two gall-bladders, was exhibited at the meeting by Dr. Purser.

DEATH OF DR. LONG, J.P.

Dr. P. Long died at his residence in St. Stephen's-green, Dublin, last week, aged seventy-three. He was in failing health for some time past, but his death was due to acute inflammation of the lungs. He was a member of the Corporation of Dublin for more than a quarter of a century, and for nearly twenty years performed the duties of assistant medical officer of the Dublin police. About three years since he was appointed to the Commission of the Peace for the city of Dublin.

Rev. Dr. Haughton has been elected President of the Royal Irish Academy for the ensuing year.

Dublin, Nov. 9th.

BELFAST.

(From our own Correspondent.)

OPENING OF THE MEDICAL SESSION: THE ROYAL HOSPITAL.

THE winter session began on Nov. 2nd, when Dr. John W. Byers delivered the introductory lecture at the Royal Hospital. After welcoming the students back, he spoke of the events of the past year which had affected the Belfast School of Medicine. These were the formation of the Medical Students' Association, the death of Dr. Thomas Andrews, and the resignation of Professor Gordon. He said they were proud of both, not only as able medical professors, but as distinguished Ulstermen, who by their writings have gained a wide reputation. Both descended from families well known in the north of Ireland, the career

of each should be a strong stimulus to those present to industry and research. Their position with their brethren in Ulster was an exception to the rule that "a prophet has no honour in his own country." By the resignation of Dr. Gordon the school at Belfast loses the services of one who was connected with it for forty-four years, during thirty-seven of which he was Professor of Surgery in Queen's College, and for a lengthened time surgeon to the hospital. Dr. Byers said that as a boy he enjoyed peculiar opportunities of knowing Dr. Gordon, whom he had been trained to respect as a valued medical attendant. This respect for his great ability deepened while a student under him, and on all occasions on which he had met Dr. Gordon as a surgical consultant, Dr. Byers said he was proud to acknowledge he had learned something. They would long miss Professor Gordon's presence in the surgery lecture-room, and his well-known figure in the dissecting-room, where he was perhaps seen to the greatest advantage. There they all remembered how easy it was to find out that the kindly surgeon had stores of self-acquired information which he was ever ready to impart to the earnest student. His loss to the school was great, and one that they all deplored; but they rejoiced that the selection of his successor had fallen on one of the able surgeons of this hospital. Dr. Byers gave a rapid sketch of the history and growth of the Belfast Medical School, and especially of the College and the Hospital. He gave statistics showing that 454 Belfast medical students had graduated in the Queen's University, and 163 in the Royal, making a total of 617, in addition to many who had obtained qualifications at other examining boards. During the last winter and summer session, 252 students had attended the hospital, and it was most gratifying to those under whom they studied to know that the only students who obtained honours at the recent examination for the M. A. O. degree (Midwifery, Gynæcology, and Diseases of Children), received their education in Belfast. The second part of Dr. Byers' lecture was devoted to the special subject of Antiseptic Midwifery.

QUEEN'S COLLEGE.

The various medical classes were opened on Nov. 4th. In the afternoon a large number of students assembled to hear the introductory lecture of the new professor of surgery, Dr. Thomas Sinclair. On coming into the class-room Dr. Sinclair was very warmly received. He gave an inaugural address on "The Relation of the other Sciences to Surgery," giving in detail some of the more remarkable advances in biology and pathology in their bearing on modern surgery.

BALLYMENA COTTAGE HOSPITAL.

According to the medical report presented at the last annual meeting of this hospital, and signed by Dr. Kidd, Dr. Ross, and Mr. Fagan (consulting surgeon), forty-eight patients were admitted during last year, besides eight remaining over from the previous twelve months. There were only two deaths, and there were several severe accidents treated and operations performed.

BELFAST HOSPITAL FOR SICK CHILDREN.

From the third half-yearly report of this most excellent and popular charity, we learn that it continues to hold its prominent position among local institutions, and that it is doing good surgical and medical work. In both medical and surgical wards there have been many interesting cases. Further, the hold that this hospital has on the public is shown by the kindness of its friends. The donations have been both numerous and most acceptable, and the excellent matron (Miss Lennox) has been enabled, through the means placed at her disposal, to supply clothing to many poor children on leaving the hospital.

Belfast, Nov. 9th.

MEDICAL APPOINTMENTS IN THE PHILIPPINES.—Complaints are made in a Madrid medical journal that the official medical appointments in the Philippine Islands are almost all monopolised by military or naval medical officers to the exclusion of civilian practitioners, who feel much aggrieved thereby. A list is given of the professors in the faculties of medicine and pharmacy in the University of Manilla, which would seem to bear out the complaint, as of the ten professors and lecturers seven are military medical officers, one a naval medical officer, while two are military pharmacists.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT the ordinary meeting of the Council held on Thursday, the 11th inst., at which all but two members were present, the death of Lady Wilson, widow of Sir Erasmus Wilson, F.R.S., was reported to the Council.

It was agreed, on the recommendation of the Dental Board, that eighteen months out of three years' instruction in mechanical dentistry might be taken before the date of registration.

The President presented the report of the result of the meeting of the Fellows and Members held on the 4th inst., and a protest against the result of the meeting was presented from Mr. T. J. Vallance. Mr. Macnamara, by permission of the Council, proposed the following resolution, which was seconded by Mr. Lund, and carried:—"That means be taken to ascertain the opinion of the Fellows of the Royal College of Surgeons as regards (*a*) Members being allowed to vote for Fellows as members of the Council of the College; (*b*) the admission of Members of the College to seats on the Council."

It was referred to the President and Vice-Presidents to draw up a circular to the Fellows to give effect to the foregoing resolution, the same to be submitted to the next meeting of the Council.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon Robert Lewer to be Deputy Surgeon-General, vice R. Webb, placed on temporary half-pay. The undermentioned Surgeons-Major to be Brigade Surgeons:—Albert Augustus Gore, M.D., vice C. E. Smith, retired; Chas. Henry Young Goodwin, vice J. Davige, retired; and Thomas Maunsell, vice R. Lewer.

ADMIRALTY.—The following appointment has been made:—Mr. Walter John E. Sumpter to be Surgeon and Agent at Sherringham.

Obituary.

GEORGE MACKIE, M.D.

DR. MACKIE, whose death occurred at Insch on the 3rd inst., received his professional education at the University of Aberdeen, and in 1846 became a licentiate of the Royal College of Surgeons of Edinburgh, and a Bachelor of Medicine of his *alma mater* in the following year, the degree of M.D. being conferred upon him twenty years later. Thirty-eight years ago he settled in Insch, where he practised his profession up to the hour of his death. Dr. Mackie was secretary of the Garioch Medical Association, and medical officer to the Parochial Boards of Insch and Premnay. He took a warm interest in the Volunteer movement, and was for many years surgeon to the local company of Rifles, and afterwards to the 4th V.B.G.H. Sincerely respected throughout the district in which his life's work was done, Dr. Mackie leaves, in addition to many friends, a widow and ten children to mourn his death.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 4th:

Bridgman, Herbert Arthur, L.F.P.S.G., Belgrave-terrace, Willesden-green.
Conolly, Charles Hamilton, M.R.C.S., Church Hill Villas, Wood-green.

[In our list published last week of gentlemen who passed for the degree of Licentiate in Dental Surgery of the Royal College of Surgeons of England, for "Tibbs, John Arthur Seymour," read [illegible] Somerset.]

DR. JOHN GORDON and Dr. Hall are announced as candidates for the vacant chair of Materia Medica in Aberdeen University.

MEDICAL MAYOR.—Mr. J. Thornton Duncan, F.R.C.P. Edin., M.R.C.S. Eng., has been elected Mayor of Stamford for the ensuing Jubilee year.

ON the 9th inst., the new cottage hospital for Paulton and district was formally opened by the Lord Bishop of Bath and Wells.

MEDICAL MAGISTRATE.—At the West Suffolk Quarter Sessions on the 26th ult., Mr. H. Newman, M.R.C.S., L.S.A., of Hadleigh, was sworn in as a Justice of the Peace.

LAST week the Queen paid a visit to the Longmore Hospital for Incurables, Edinburgh. Her Majesty, who expressed satisfaction with the result of her inspection, has since given £50 to the funds of the institution.

WE have received from Messrs. Pratt a rubbing from a memorial brass which was erected on the 8th inst. in the garrison chapel at Woolwich to the memory of Surgeon-General Oliver Barnett, C.I.E., Army Medical Staff.

HYDROPHOBIA AT ODESSA.—It is stated by a St. Petersburg journal that the first experiences of the Odessa Pasteur Institute have been far from encouraging, five patients having died out of a very moderate number treated by Pasteur's method.

MUNICIPAL HONOURS.—No less than three members of the medical profession have just been elected to the Town Council of Leicester—viz., Mr. C. Crossley, surgeon to the Infirmary, Mr. Lankester, and Dr. Clifton. There are now five medical men at the municipal board.

THE ABERDEEN GRADUATES' CLUB.—In consequence of the recent accident to Dr. Alexander Bain, Lord-Rector of the University of Aberdeen, he will be unable to preside at the dinner of the Aberdeen University Club, London, on Wednesday next. Dr. James Alexander Campbell, M.P. for the University, has consented to take the chair on that evening.

SMALL-POX AT JAMAICA.—Intelligence has been received of the existence of an epidemic of small-pox at Kingston, Jamaica. On the 13th ult. there were no fewer than 362 cases under treatment, and the deaths had been exceptionally numerous. The inhabitants were leaving the town in very large numbers, as the disease was rapidly increasing.

NOTTINGHAM GENERAL HOSPITAL.—The 101st anniversary meeting of this institution was held on the 4th inst. During the past year 1602 in-patients and 8718 out-patients have been treated, at a cost of £6439. The income from annual subscriptions has fallen from £2448 in 1882 to £2314 in 1885, and the financial position of the hospital is far from being a satisfactory one.

THE LATE MR. CHILCOTE.—A meeting was held on the 4th inst. to consider what steps should be taken to perpetuate the memory of the late Mr. Chilcote, surgeon, of Babbacombe, and a committee was appointed to consider the form of the proposed memorial and to collect subscriptions. Three methods of commemoration were suggested—viz., the purchase of six almshouses, the foundation of a cottage hospital, and the erection of a dispensary.

POISONOUS MUSHROOMS.—It is reported that a very considerable quantity of injurious fungi is now finding its way into the markets as mushrooms, and in West Kent several cases of serious illness, caused by the consumption of what appear to be button mushrooms, but which are really poisonous fungi, are reported. These poisonous mushrooms have a yellowish appearance when cut, but otherwise bear a great resemblance to the edible mushroom.

DEATH UNDER CHLOROFORM.—On the 9th inst. an inquest was held at the Huddersfield Infirmary on the body of a man who had died at that institution whilst undergoing under chloroform an operation for cancer in the mouth. Medical evidence was given that death arose from failure of the heart's action, brought about by the administration of the chloroform, and the jury found a verdict accordingly, adding that the chl[illegible] Coroner[illegible]

A CENTENARIAN.—A widow residing at Newtown, Montgomeryshire, has just attained her 102nd year, having been born in 1784. Her health is stated to be excellent, and her eyesight is so good that she is able to read and thread a needle without the use of glasses.

EPSOM COLLEGE.—Some Exhibitions, reducing the charge for board and education to £31 10*s.* a year, are to be competed for in December by sons of medical men. The successful candidates will enter the College in January. Application should be made before the end of November to the Secretary of the College, at the office, 37, Soho-square.

DERBYSHIRE GENERAL INFIRMARY.—The 77th anniversary of this institution was celebrated on the 4th inst., when the secretary stated that the number of patients admitted during the year was 3540, of whom 1312 were in- and 2228 out-patients, exclusive of 2000 casualty cases. The in-patients number 89 less, and the out-patients 318 more, than in the preceding year. The total receipts for the year were £6067, and the expenditure was £6594.

THE CODNOR SEWERAGE QUESTION.—A meeting of the ratepayers of Codnor was held on the 4th inst. to discuss a plan for dealing with the Codnor sewage. The scheme, which was proposed by Mr. Parkin of Nottingham, was adopted, its estimated cost being £3500, and it will forthwith be submitted to the Basford Rural Sanitary Authority. The village, which contains a population of 4500 is in a very defective and insanitary condition.

MANCHESTER AND SALFORD MEDICAL CHARITIES.—The report which was read on the 8th inst. at the annual meeting of the General Committee in connexion with the Manchester and Salford Hospital Sunday and Saturday Fund, stated that last year there was a net increase of £427 over the amount contributed in 1884. This year the sum raised showed a decrease of £522, as compared with that received last year. The Sunday collections for 1886 amounted to £4618, and the Saturday collections to £2924.

THE HOSPITALS ASSOCIATION.—This week's number of *The Hospital*, the new journal of the Hospitals Association, contains a contribution from his Royal Highness the Duke of Cambridge, who has intimated his intention of being present at the conversazione of the Members and Representatives of Hospitals and Asylums throughout the country, which will be held at the rooms of the Medical Society of London, 11, Chandos-street, W., on Wednesday, the 17th inst.

THE DOG REGULATIONS.—The statistics prepared by the police respecting the working of the dog regulations for the month of October were published on the 6th inst. During the month, 2157 dogs were seized, and 22 were killed as rabid. Of these last, however, only four were, on examination, pronounced to be affected with rabies. Since the new regulations have been in force, the report states that the number of rabid dogs found in the streets has rapidly declined. In 1885 the number was higher than ever before. In July of this year the number was 16, in August 13, in September 9, and in October, as above stated, 4.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.—The quarterly meeting of this Association was held at Bethlem Hospital on Tuesday, the 9th Nov., under the presidency of Dr. Savage. Mr. Hayes Newington read a paper on the tests which should be made use of in deciding as to the fitness of patients for discharge, especially dealing with the subject in its relation to cases of suicidal tendency. Dr. Savage followed with a paper on the question from the homicidal point of view, and a discussion ensued, in which Drs. Blandford, Rayner, Hack Tuke, and C. M. Tuke took part.

BEQUESTS.—Miss Lowe, a lady who died recently at Blackpool, has left amongst other legacies £4500 to the Bolton Infirmary, and £1000 to found an infirmary for Blackpool.—The late Dr. Grigor of Nairn has left £1000 each to the Universities of Aberdeen and Edinburgh for the purpose of founding a medical bursary.—The following bequests have been received by the treasurers of the Devonshire Hospital, Buxton, during the past week: under the will of John Slack, Esq., J.P., late of Bowden Hall, Chapel-en-le-Frith, Derbyshire, £136 18*s.* 1*d.*; and under the will of Richard Wheatley, Esq., late of Royds House, Mirfield, Yorkshire, £100.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARKER, GLANVILLE, M.R.C.S., has been appointed House-Surgeon to the Central London Ophthalmic Hospital, Gray's-inn-road.

GRIFFITHS, P. RHYS, M.B., B.S. Lond., has been appointed Medical Officer to Out-patients at the Glamorganshire and Mon. Infirmary, Cardiff.

HICKER, LEWIS, M.B.Dur., M.R.C.S., L.S.A., has been appointed Junior House-Surgeon to the Bury Hospital, vice J. H. Jones, promoted.

JONES, J. H., M.R.C.S., L.R.C.P.Lond., L.S.A., has been appointed Senior House-Surgeon to the Bury Hospital, vice T. T. Hamilton, L.R.C.S., L.R.C.P., L.S.A., resigned.

MALE, HERBERT C., M.B.Edin., M.R.C.S., has been appointed Medical Officer to the Training Ship *Shaftesbury*, Grays, Essex.

OWEN, H., B.A., M.B.Cantab., M.R.C.S., has been appointed Visiting Medical Officer to the Royal Pimlico Dispensary, vice F. M. Evans, M.R.C.S., resigned.

SHIRLEY, M. B., M.R.C.S., L.R.C.P., has been appointed Honorary Surgeon to the Batley and District Cottage Hospital.

STEWART, ROTHSAY C., M.R.C.S., L.S.A., Assistant Medical Officer, Peckham House Asylum, Peckham, S.E., has been appointed Assistant Medical Officer to the County Lunatic Asylum, Leicester.

WATTS, A. T. G., B.A.Cantab., M.R.C.S., L.S.A., has been appointed Resident Medical Officer to the Royal Pimlico Dispensary, vice H. Owen, M.A., M.B.Cantab., resigned.

Births, Marriages, and Deaths.

BIRTHS.

BRATTON.—On the 5th inst., at College-hill House, Shrewsbury, the wife of J. Allan Bratton, M.A., L.R.C.P., of a son.

MACLACHLAN.—On the 1st inst., at St. Blanes, Lockerbie, the wife of James MacLachlan, M.B., of a daughter.

SHILLINGFORD.—On the 2nd inst., at Hill-street, Peckam, the wife of Frank Shillingford, M.R.C.S., of a daughter.

SOUTAR.—On the 6th inst., at Barnwood, near Gloucester, the wife of James Greig Soutar, M.B., of a son.

MARRIAGES.

COOK—ROBERTS.—On the 2nd inst., at the Parish Church, Llangwstenin, North Wales, Henry S. Cook, M.R.C.S., L.S.A., of Birmingham, to Ethel Lydia, eldest daughter of the Rev. E. Roberts, M.A.Oxon., Rector of Llangwstenin.

PERKINS—CHAPMAN.—On the 9th inst., at St. Sidwell's Church, Exeter, Charles Steele Perkins, M.B.Lond., M.R.C.S., of Sydenham, to Lily Blouis, third daughter of Edward Chapman, Esq., of Forest-hill and Sydney, N.S.W.

PRATT—BEAKLEY.—On the 9th inst., at Thorney, Dr. Reginald Pratt, of London-road, Leicester, to Frances E. Beakley, daughter of Christopher Beakley, Esq., of Thorney, near Peterborough.

STARLING—HOWSE.—On the 5th inst., at Onslow Chapel, Kensington, by the Rev. J. M. Bergin, Edwin Alfred Starling, M.B., M.Ch., of Tunbridge Wells, to Helena Sarah, eldest daughter of the late Nathaniel Howse, of Witney, Oxon., and Grahamstown, South Africa.

WILSON—GUTHRIE.—On the 10th inst., at Marylebone Presbyterian Church, London, by the father of the bride, Clarke Wilson, M.B., C.M., of Bath, to Annette, eldest daughter of the Rev. D. K. Guthrie, of Liberton, Midlothian.

DEATHS.

FARRE.—On the 10th inst., at Elsham-road, W., Frederic John Farre, M.D., aged 82.

HENRY.—On the 6th inst., at Dundrum, co. Dublin, Richard Henry, M.D., formerly of Lower Baggot-street, aged 38.

HOWE.—On the 24th ult., at Springfield House, Marple, John Howe, M.R.C.S.Eng., L.S.A., aged 70.

NAIRNE.—On the 5th inst., at Mossley, Beckenham, Robert Nairne, M.D., of Trinity College, Cambridge, F.R.C.P., Honorary Commissioner in Lunacy.

SHARPE.—On the 9th inst., at The Ferns, Oakleigh-road, Whetstone, Richard Sharpe, M.D., late of Wormley, Herts, aged 67.

SHAW.—On the 4th inst., at Baring-crescent, Exeter, after a long and painful illness, Henry Shaw, M.D., M.R.C.S.

STEWART.—On the 11th ult., at Venezuela, South America (of fever), Eliza Jane, the wife of William Stewart, M.B., late of London, and third daughter of Hilton and Alice Halhead, late of Liverpool.

TUCK.—On the 8th inst., suddenly, at Seaford, Sussex, Buckmaster Joseph Tuck, M.R.C.S., aged 49.

N.B.—A Fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

JOHN HUNTER.

As our readers are aware, the site of John Hunter's house at Earl's Court has recently been cleared for the erection of villas, and will in future be known as Barkston-gardens. A correspondent reports that it is now the great wish of the local medical and other residents that a statue of the great anatomist should grace the centre of the proposed gardens, which will mark almost the identical spot on which the house so lately stood. Otherwise, all trace of John Hunter's connexion with Earl's Court must for ever be locally obliterated. The owner of the property is in favour of the scheme, and a suitable appeal for funds will shortly be made to the public—an appeal which will no doubt fully realise sufficient to properly carry out the object in view. As preliminary expenses, however, are indispensable, gentlemen who are willing to join the initial committee, and to subscribe their quota to the expenses of starting the movement, are invited to communicate with Mr. F. P. Pelham, 172, Finborough-road, South Kensington.

Mr. H. Towers-Smith.—The physician in question would have done well to communicate with the practitioner in attendance, as the eminent surgeon whom he quotes does so constantly. Our correspondent is not, however, much the worse for the course taken by the friends; it has resulted in the endorsement both of his diagnosis and treatment.

THE APOTHECARIES' SOCIETY AND THE CONJOINT BOARD.

To the Editor of THE LANCET.

SIR,—I should feel much obliged and indebted to every Poor-law Medical Officer (whether belonging to our Association or not) if he would send me a post-card, directed to 3, Bolt-court, Fleet-street, London, with "Yes" or "No" upon it, after the name and address of the sender. "Yes" meaning the writer's approval of the Society of Apothecaries being admitted to the Conjoint Board.—I am, Sir, yours truly,

Nov. 10th, 1886. J. WICKHAM BARNES.

PARANOIA.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 23rd, p. 786, you comment on the term "paranoia," as used by the physicians attending the late King of Bavaria in designating the form of mental disease from which the unfortunate King was suffering. Will you allow me to point out to your readers that German alienists have for a few years past used the term "paranoia" for that kind of mental disease which they formerly mostly designated by the term "originäre Verrücktheit," and which English physicians would call "insanity with delusions," or which by some is called "monomania."

I am, Sir, yours faithfully,

Freiburg, i. Baden, Nov. 7th, 1886. C. Bannister.

THE UNUSUAL COINCIDENCE AT ST. THOMAS'S HOSPITAL.

Mr. H. E. Armstrong.—Careful inquiries were made by the house-surgeon, Mr. Brockett, who visited the place where the patients lived, and also went to their friends, who did not know their former address. The house from which they had been removed was apparently in a good sanitary condition. All that could be learnt of their former residence was that their landlord was a man who sold cat's meat, much of which smelt badly. The patients removed because of bad smells.

Australian.—Amongst others, the *Australasian Medical Gazette*, which is published in Sydney. There are medical agents in the colonies, the publisher of the above-mentioned journal being one.

Mr. J. Williams (Llanberis).—Yes.

TREATMENT OF GUINEA-WORM.

To the Editor of THE LANCET.

SIR,—I beg to make the following suggestions about the mode of procedure in cases of burrowing guinea-worms through your journal in reply to your correspondent, "Reader."

In these cases, when the worm is seen below the skin, even in a short space, the best thing to do is to cut directly on the worm right through the skin till the cellular tissue is reached. The incision must be about a line or a line and a half in length. The best instrument for it is a sharp-pointed tenotomy knife or a narrow scalpel. Widen the wound with two hooks, one on each side; then raise the cellular tissue with tiny forceps, and remove it, and with it also the adipose tissue that may come in the way. By two or three slight touches of the knife the operator will come down upon the casement of the worm. While opening the casement take care not to injure the body of the worm; otherwise the contents would spurt out and inflammation would be set up from the ichorous nature of the fluid. On opening the casement the worm will come into view, which is recognised by its glistening appearance. Pass a probe below the body of the worm and, lifting it, pull gently and slowly, taking care not to break it. By this procedure at least one end will come out. When one end is out, wind it round an ivory peg or a bit of stick, and to keep it soft, tie over it a small leaf of some harmless plant smeared with a little salad oil, and change it every day till the worm is out. Try to pull it out every day by degrees. When the worm is very obstinate, throw a stream of water three or four times a day from a height of four or five feet on the part. To make sure of the presence of the worm, apply a little ether to the part, and a distinct hard cord will be seen and felt by the finger. This is from the experience I had at Oorun when in medical charge of that station. Oorun and places around it are well known for guinea-worms during the monsoons. I had the good fortune to remove some 500 worms during the short interval of three months.

I am, Sir, yours truly,

CONASJO PESTONJI, G.G.M.C.,
Medical Officer, Bombay Native Dispensary.

Bombay, Chundunwady, Oct. 19th, 1886.

TRIPLETS AND TWINS IN CONSECUTIVE PREGNANCIES.

To the Editor of THE LANCET.

SIR,—As a case of triplets followed by twins in the succeeding pregnancy must be uncommon, perhaps a short account of the case might be interesting to some of your readers.

On Jan. 13th, 1884, I delivered Mrs. B——, wife of a working malster, of three living children, two girls and a boy, the presentations being head, foot, and breech; there was but one placenta, and each child was contained in a separate sac of membranes. The children were small but not puny; they lived for seven months, dying within a few hours of each other of diarrhœa and convulsions. The mother made a good recovery. On Oct. 30th last, I delivered the same patient of twins, girl and boy; presentations head and breech. In this case there were two placentæ, which came away without any trouble at intervals of about five minutes. The children were of a good size, the boy being above the average. The mother's family history in an obstetric sense is interesting, one of her maternal aunts giving birth to twins four times, and another three times.—I am, Sir, faithfully yours,

WILLIAM B. HALLOWES, L. & L.M.K.Q.C.P.I.

Newark-on-Trent, Nov. 2nd, 1886.

WALTER MOXON MEMORIAL.

To the Editor of THE LANCET.

SIR,—In answer to Dr. Robert Harris's question in your last issue, I should be glad to be allowed to state that steps are being now taken to raise a memorial to the late Dr. Moxon. As so many outside the walls of Guy's Hospital knew and appreciated his talents, it has been determined not to confine the subscriptions to the Guy's *clientèle*. Sir William Jenner (as President of the Royal College of Physicians) has kindly consented to be president of the Fund. Sir James Paget, Sir William Gull, Sir Andrew Clark, Sir Henry Acland, Sir William McArthur, the President of the Royal College of Surgeons, and the Chairman of the late Dr. Moxon's Life Office, have agreed to act as vice-presidents. The matter will in the course of a few days be discussed by the staff of the hospital, and then it is probable that a meeting will be called to consider the form the memorial should take. Meanwhile I would be glad to receive the names of any desirous of joining in the movement.

I am, Sir, yours faithfully,

R. CLEMENT LUCAS.

the chlore-square, Nov. 8th, 1886.

adding tha.

JEWISH BURIAL.

MR. FREDERICK W. LOWNDES communicates to us a letter he has received from Mr. Barnard Levy, President of the Burial Board of the Liverpool New Hebrew Congregation, giving the following very interesting account of the simple and inexpensive manner in which the funerals of members of the Jewish persuasion are carried out:—

"About two hours after death the body is removed from the bed and carefully placed on the ground, with clean straw or shavings under it, and covered over with a clean sheet. It is then left for about thirty-six hours. On the expiration of that time the body (if its state permits) is washed by persons appointed for that purpose, who bring the necessary appliances. The shrouds, which cost for an adult about 17s., are then placed on the body, which is then consigned to a common deal coffin (cost, 16s.). At the time fixed for the funeral the family and friends assemble. We have no scarves, plumes, or anything of the kind, and anything in the way of refreshments is unheard of. The cost of a hearse varies from 12s. 6d. to £1 1s., and, as a rule, we employ very few black coaches. Personally, I do not approve of them, and I usually recommend the employment of cabs at a cost of 5s. 6d. each. On arrival at the burial-ground the coffin is carried on a hand-bier to the chapel, where the usual religious service is held, and thence to the grave, which is never bricked, and in which we never inter more than one body. The expenses, of course, vary with the number of coaches employed. In conclusion, I think I may say that the last services to the dead as conducted by my co-religionists are carried out in a reverential spirit, and will bear favourable comparison with those of any other sect."

Mr. F. Jeffree.—The title of the book is, "Students' Guide to the Diseases of Children."

PNEUMONIA.

To the Editor of THE LANCET.

SIR,—The case of the outbreak of an epidemic of pneumonia described in a letter by Dr. C. J. Denny, and published in your issue of Sept. 18th last, must have been read with interest by many; but it is a mistake to imagine that such cases occur only in malarious districts. Outbreaks of this nature have been known to occur in prisons, barracks, &c., which stood in districts to which the epithet "malarious" could hardly be applied. I think the infectious nature of at least certain forms of pneumonia is agreed upon by most pathologists; and the "micrococcus pneumoniæ crouposæ" of Friedländer has often been cultivated and studied, and mice have been infected with pneumonia and pleuritis resulting from injections from pure cultivations. We must rather be inclined to believe that wherever these micrococci find the conditions necessary for their existence (not to be found only in malarious districts) they will multiply and exhibit their pathogenic nature. It is a matter to be regretted that Dr. Denny did not search for them, or tell us how he coped with the evil; for these cases, though not of frequent occurrence, may come under the notice of any practitioner quite unawares.

I am, Sir, yours obediently,

Sept. 22nd, 1886. FREMDLING.

COCAINE.—BONE DRAINAGE-TUBES

To the Editor of THE LANCET.

SIR,—May I ask some of your readers for answers to the following two quest

1. Whether after using cocaine as a local anæsthetic by injection sub cutaneously they have noticed a tendency to recurrent hæmorrhage, the cocaine appearing for the time to constrict the vessels, and a corresponding reaction taking place? There is often free hæmorrhage from a surface where it had entirely ceased. I have noticed this in several cases.

2. What is the "life" of a decalcified bone used in a wound as a drainage-tube? I find that after twenty-four hours the tubes completely collapse, and lie in the wound like a piece of tape and fail to drain it at all. So quickly also do they appear to dissolve in the secretions that those I have used have also in twenty-four hours become as thin as tissue paper, and do not last nearly long enough to be useful. I may mention that I prepared the bones myself, using very dilute hydrochloric acid as the solvent. Is the period I have named the usual one for them to last? And is there any maker who supplies them?

I am, Sir, yours obediently,

H.M.S. *Bellerophon*, Halifax, Oct. 24th, 1886. A. G. P. GIPPS.

TREATMENT OF GONORRHŒA.

To the Editor of THE LANCET.

SIR,—I have lately had an opportunity of trying in two instances a plan I have wished to try. Two patients came to me with evidently incipient gonorrhœa; it was, however, quite in the first stage, and confined to the fossa navicularis. I gave each a flexible catheter, and a bottle with P.B. carbolic, one drachm, and olive oil, three drachms, and told them to anoint the catheter with the oil, and pass it into the urethra about an inch and a half every hour for five hours. The next day they returned without any symptoms of gonorrhœa, but the urethra feeling sore and tender, and there have been no symptoms since. Of course, this could only be used when the disease is detected at once. I think a milder application might have answered, possibly one in eight, but I wished to make sure.

I am, Sir, Yours truly,

London, November, 1886. G.

THE VIENNA MEDICAL SCHOOL.

ACCORDING to the prospectus for the winter semester of 1886-87 the number of students (ordinary and extraordinary) during the last semester was 2289—2149 ordinary and 140 extraordinary. Those from the Austro-Hungarian empire numbered 2115, and those from abroad 174. The whole number of students in all departments of the University during the semester was 5358.

Mr. David Berry, M.B.—See THE LANCET for Oct. 27th, Nov. 3rd, and Dec. 22nd, 1883.

B.—Students generally consider the L.F.P.S.Glas. the easier examination.

VACCINATION AND ERYSIPELAS.

To the Editor of THE LANCET.

SIR,—On Jan. 21st of this year I vaccinated two infants, three and four months old respectively, from a healthy child of four months, with four typical vesicles with little or no areola. Two days afterwards the mother of one brought the child to show me its arm, which was in a state of erysipelatous inflammation from the shoulder to the elbow, and the same evening the father of the other infant came to say that it was so ill from the inflammation of its arm it could not be brought out and he was sure there was something wrong. I called next morning and found this child also suffering from acute erysipelas from the shoulder to the wrist. I immediately then called and saw the vaccinifer and found that infant in perfect health; the areola faded, the vesicles running a normal course, and the mother somewhat indignant at the idea of any disease being communicated from her offspring. These cases caused me considerable anxiety, but fortunately both recovered in a week or ten days. There was not the least attempt at the formation of any vesicles, and at the end of a week just a few marks of the scarification were all that could be seen. The homes of the infants were more than a mile apart, and I found nothing wrong with the sanitary arrangements. I need hardly say that the lancet was scrupulously clean, washed before and after use, and I subsequently vaccinated, but from other infants, fourteen children, all of whom did perfectly well.

In a record of over six thousand cases these are the only two in which I have seen erysipelas immediately follow vaccination. Ziemssen, vol. ii., page 436, mentions a case of transmission of erysipelas by vaccination, but there the disease appeared in the vaccinifer the day after the lymph was taken. The blame that I and the practice of vaccination incurred, I can assure you was by no means slight.

I am, Sir, yours truly,
Birmingham. H. FLAMANK MARSHALL, M.B. Lond.

"COMPULSORY ATTENDANCE AFTER REJECTION AT EXAMINATION."

To the Editor of THE LANCET.

SIR,—With regard to the article under the above heading in your last issue, I think it would be a most unjust proceeding on the part of the Colleges to compel all candidates to undergo a further course of study at a medical school. There are several men holding both medical and surgical qualifications who have extensive practices, and who may wish to become members of other Colleges. They present themselves, and through some mishap fail. I ask the question, How can these men leave their practices and attend school, according to your recommendation? I am, Sir, yours faithfully,
Nov. 6th, 1886. JUSTICE.

"FETID URINE."

To the Editor of THE LANCET.

SIR,—Referring to Dr. Neale's note in the last number of THE LANCET, and his use of boracic acid during the past two years, I beg to say that I have used boracic acid for upwards of eight years with good effect in many cases in which the urine becomes foul and ammoniacal; and I recommended it for this purpose at page 175 of the first edition of my work on "General Paralysis of the Insane," published in 1880; also recently, in the second edition, page 403. The drug is very useful in some of the urinary conditions arising in many forms of cerebral and spinal disease. Polli was, perhaps, the first to employ it in chronic cystitis. I am, Sir, yours faithfully,
London, Nov. 8th, 1886. WM. JULIUS MICKLE, M.D.

Mr. A. E. Robertson.—1. Yes, on receipt of six stamps in addition to cost of advertisement.—2. Uncertain.—3. Better write to the Secretary of the Court.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In your last number, page 901, it is stated that Lady Edwards has just given £750 to the Bradford Infirmary, to endow a children's cot in memory of her late husband. Will you allow me to correct this, and point out that it is the *Halifax* Infirmary which has received this donation—an institution in which the late Sir Henry Edwards always took the warmest personal interest.—I am, Sir, yours faithfully,
Halifax, Nov. 9th, 1886. E. WEST SYMES, M.D.

THE APPROACHING ELECTIONS.

MR. THOMAS LAFFAN writes to urge the absolute necessity for the presence of legal representatives of the different candidates for election to the Medical Council at the scrutiny of the votes.

A. de B. has not enclosed his card.

THE REPRESENTATION OF SCOTCH PRACTITIONERS.

A CORRESPONDENT, alluding to Dr. Pirie's letter, published in our columns on the 23rd ult., states (1) that it was Dr. Morton, in his Glasgow address, who first endeavoured to open the old wound between the Corporations and the Universities; and (2) that anyone looking at the list of Dr. Bruce's supporters can easily see he is not the nominee of the Universities, but of general practitioners. While it is quite true that Dr. Bruce was at one time examiner in Medicine at Aberdeen University, the fact is that he severed his connexion with that body about seventeen years ago, and even then he was an advocate of medical reform.

Rev. J. H. Wanklyn.—The communication is in the nature of an advertisement.

EXTRACTION OF CATARACT.

To the Editor of THE LANCET.

SIR,—In Dr. Wolfe's Introductory Lecture, published in your issue of Nov. 6th, I see that he thinks it very unfortunate that v. Graefe's last work, his method of extracting cataract, has not proved a success. In this I think he is mistaken; v. Graefe's extraction, somewhat modified, is employed by many London surgeons with great success, and I have had no inconsiderable experience of the operation. Since 1871 I have employed it in most cases of hard cataract which I have extracted in India; and in the only statistics which I happen to have by me—from January, 1882, until April of this year—I find that I extracted over 500 cataracts by this method. Dr. Wolfe mentions that he extracted twenty cataracts successfully in one month in presence of four of his colleagues. In January last I extracted twenty-three in the Bombay Ophthalmic Hospital, all of which were successful; and the previous ten were also successful. I have seen Dr. Wolfe and many other surgeons operate; and I believe that various plans of extracting cataract are equally successful, if a surgeon thoroughly understands, and is experienced in, his own favourite method.—I am, Sir, yours faithfully,

G. A. MACONACHIE, M.D.,
Blackheath, Nov. 8th, 1886. Surg.-Major, I.M.D.

PLACENTA PRÆVIA.

To the Editor of THE LANCET.

SIR,—Two or three years ago I placed on record in your pages a case of presentation of funis, arm, and leg, with the happiest results to both mother and child. Last week I was fortunate enough to save both mother and child in a case of placenta prævia at the seventh month. I had been engaged to attend Mrs. L—— of this parish about Christmas, but was sent for in a hurry on the 17th ult., as the woman was "flooding desperately," but without pain. On arrival I diagnosed the case as one of placenta prævia, but as the loss was not very great, I resolved to temporise awhile, ordering rest in bed, cool room and drinks, nourishing diet, acid astringents, but no stimulants. Affairs went on *statu quo* until the evening of Nov. 5th, when sharp labour pains came on, the placenta preceding the rapid birth of a seven months' child, apparently stillborn, but revived after protracted attention. Up to the present date both mother and child are doing well. I am, Sir, yours faithfully,
Cley-next-Sea, Norfolk, Nov. 10th, 1886. W. SUMPTER, M.D., R.N.

HEREDITY IN LOWER ANIMALS.

To the Editor of THE LANCET.

SIR,—I can confirm Mr. Hawkins-Ambler's remarks in your last issue regarding kittens sitting up untaught, having owned a cat trained to beg which produced three different lots of kittens, some of which sat upright without being taught, or directly copying their mother. (Mr. Darwin was much interested in this example.) Many years ago I saw a Skye terrier whose skull had been fractured by a spade. She subsequently produced epileptic puppies. I am, Sir, yours faithfully,
Malvern, Nov. 10th, 1886. STANLEY HAYNES, M.D.

MELANCHOLIA AS THE RESULT OF INOCULATION FOR RABIES.

Mr. J. R. Ware.—On inquiry we find no reason for the statement of our correspondent. Both the men have been on duty since the inoculation, neither of them having been placed on the sick-list. There have been no complaints either from them or the other members of the force.

Mr. J. A. McLeay might apply to Messrs. Moore and Son, Houndsditch.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Haward, London; Mr. T. Bryant, London; Dr. Rayner, Hanwell; Mr. Thos. Smith, London; Mr. W. Medical Diary for the ensuing Week.

Monday, November 15.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. J. Hughlings-Jackson: A Rare case of Epilepsy.—Mr. Victor Horsley: Note on the Artificial Production of Epilepsy in Guinea-pigs, illustrated by Photographs on the screen with Lime-light.

Tuesday, November 16.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. W. R. Williams: Vegetable Tumours in relation to Bud Formation.—Dr. Hale White: Cerebro-spinal Meningitis leading to Œsophageal Abscess.—Mr. C. L. Hudson: Congenital Contraction of Stomach.—Dr. N. Moore: Aneurysm of Coronary Artery.—Mr. E. H. Fenwick: Carcinoma of Vesicula Seminalis.—Mr. D'Arcy Power: Two cases of Imperforate Anus.—Dr. H. Sainsbury: Cystic Tumour of Ileo-cæcal Valve. Card Specimens:—Dr. Savill: Meningeal Hæmorrhage.—Mr. Sluitsoek: Chondrifying Sarcoma of Bladder.—Dr. Pasteur: Lung in Chronic Pleurisy.

Wednesday, November 17.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Mondays and Thursdays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
SOCIETY OF ARTS.—Opening Address by Capt. Douglas Galton, Chairman of the Council.

Thursday, November 18.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Dr. John Williams: Cancer of the Uterus (Harveian Lecture).

Friday, November 19.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
CHARING-CROSS HOSPITAL MEDICAL SOCIETY.—7.45 P.M. Mr. J. Astley Bloxam, F.R.C.S.: Bed-sores.

Saturday, November 20.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months..... £0 16 3
To CHINA AND INDIA ..... One Year 1 16 10
To THE CONTINENT, COLONIES, AND UNITED STATES ..... Ditto 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to advertisements or subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

An Address
ON
FINALITY IN SURGERY.

Delivered in the Surgical Section of the Academy of Medicine in Ireland, at the Opening Meeting, Nov. 12th, 1886,

BY SIR W. STOKES, M.D., M.CH. UNIV. DUB.,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND, ETC. ETC.

GENTLEMEN,—On the present occasion I have in the first instance to acknowledge the signal mark of confidence that has been shown me by this College in placing me in the position I now occupy—one that carries with it, as you know, the duty as well as privilege of presiding during the coming session over the deliberations and discussions in this section of the Academy. To be appointed to this office I deem one of the highest honours that can be conferred on any member of our calling, and that I am sensible of having been considered worthy of it is the truth. I shall ever remember with satisfaction that in the formation of this Academy, which was a welding together of all the Societies in this city connected with our profession, and a public declaration and recognition on our part of the unity of medical science, I took a not wholly inactive part, believing that from a vivifying contact of its branches would be derived a new and powerful impulse to its progress, and to the pleasure of finding that these anticipations have been more than realised is added for me the pardonable pride of having first been entrusted with the responsible duties of secretary to this section, and now with those of its president.

It is not my intention to make a retrospect of the surgical work done by this section since its formation, though such might be interesting and possibly of utility. That which was accomplished last session was, I think, a fair sample of what was done in the previous three sessions; and when we consider the range and importance of the communications made—On Dry Dressings in Antiseptic Surgery, by Mr. Kendal Franks; Perforation of the Membrana Tympani, by Dr. M'Keown; the Radical Cure of Hydrocele, by Dr. M'Ardle; Pharyngocele, by Mr. Wheeler; Ectopia Vesicæ, by Professor Bennett; Bone Drainage, by Professor T. Stoker; the Surgery of the Brain, by Dr. Coppinger; the Treatment of Scrofulous Cervical Glands, by Mr. Kendal Franks; Ununited Fractures, by Dr. Fitzgibbon; and the Treatment of Stricture by Electrolysis, by Dr. Hayes,—we can recall a group of papers that were at once comprehensive and practical, furnishing proof not alone of earnestness, ability, and zeal, but also no lack of power to sustain the reputation that has been won for the Dublin School of Surgery by our predecessors.

One of the great, in truth the chief, uses of societies such as this is to furnish opportunities for that mental friction, that touch of mind to mind, and contact with the spirit of work, which are such important factors in giving a stimulus to effort, fostering that union among workers which is not only a force in promoting scientific progress, but also one which leads to that kindly feeling and fellowship which should exist among all who honestly make effort to advance our science. These advantages, as well as others, must always follow fair, temperate, and earnest scientific discussion, and there are few now, if any, who would endorse an opinion I remember having heard expressed in the old Pathological Society, which was that one of its chief merits was the absence of all debate or discussion on the specimens exhibited or on the communications made thereon, a sentiment which was at the time received with loud applause. On another occasion I heard a somewhat similar utterance from one deservedly eminent in our profession, who, deprecating heated discussion on scientific matters and warning his hearers against it, reminded them that it is only when water is clear and tranquil that we are enabled to see the treasures that lie beneath it. But we have to do more than "see," and it must not be forgotten that it is only after the storm that the fairest shells are cast upon the beach, and the opportunity given us not alone to see them in all clearness, but to study, to learn from, appreciate, and treasure them. To Pericles are given the words: "Debate, we hold, does not mar action; the mischief is rather setting to work without first being enlightened."[1] But for discussion or debate to be fruitful, it is essential that there should be a rigid avoidance of all personalities, and a maintenance of that courtesy which characterises and distinguishes a scientific and intellectual aristocracy.

It has always been a source of regret to me since the formation of this Academy that so many members of our profession, both here as well as in the provinces, men of large and varied experience and unquestioned ability, have played so secondary a part in its practical working. Why this should be has always been inexplicable to me, for assuredly the necessity for conference, criticism, and mutual help is, especially in this section, owing to the area of surgery having of late become so widened, far greater now than it has ever been. Its life can best be maintained by the persistent recording of accurately observed facts, seen under many phases and circumstances, like the ever-varying pictures in a kaleidoscope; and the more earnest labourers that come into the field and volunteer for so good a work, the sooner may we hope for the realisation of what should always be our common aim and aspiration—the dispersion of error and diffusion of truth. It has been well said by our brilliant countryman, Bishop Magee, that no scientific student or teacher ever feels that he has a vested interest in the benefits resulting from any discovery or knowledge he may have acquired. He feels that the result of his toilful search is not his property alone, but belongs to all men, is revealed to him only that through him all men may become possessors of it, and that to conceal or utilise it solely for his own benefit is a miserly selfishness that carries with it its own Nemesis. At present there is all the greater necessity for co-operation in scientific research from the existence of many difficulties and chilling influences that in our profession beset us and that we have to contend against, among which may be mentioned the disturbed political condition that now unhappily exists in these countries; for assuredly the scientific advancement of a nation is always greatest when, instead of dissatisfaction and agitation, it has contentment and rest. This chilling influence is accentuated from the existence of a system of rule that, like all popular governments that exist or ever have existed, is not only careless and indifferent, but often distinctly antagonistic to scientists and their work. A different condition of things is observed among several of our continental neighbours, notably Germany and Austria; and the result is seen in the fact that of late years we look to a very large extent for light and leading to the great scientific centres in these countries, the Governments of which do so much to aid and foster original scientific research. Here a scientist, unless he happens to be among the favoured few possessed of private fortune, must dilute his work with what will yield more immediately a practical and tangible result. This must be regarded as a misfortune—one which is felt as such not only in a limited and local sense, but in a widely national point of view; for it has resulted in the too frequent transplantation of scientific laurels to countries and climes not our own. Again, there is the present epidemic of that combined hysteria, sentimentalism, and folly which has done so much to mar the intelligence and sap the judgment of so many men, as well as women, and which has resulted in the State placing cruel and senseless fetters on those whose aim and life-work have no objects but the advancement of our science and the welfare of mankind. It has been well said, "There are many years, but one sentiment, between the persecution of Galileo and the onslaught on vivisection." I need not dwell further on this, as the able and eloquent address delivered in this hall by our President, Dr. McDonnell, on "What Experimental Physiology has done for Surgery," is doubtless still fresh in the recollection of most of my hearers. Lastly, there is the existence of that class which is deserving of our heartiest contempt, the "critic-asters," as they were termed by Charles Reade—a class both in, I regret to say, as well as out of our profession, who apparently never tire of praising dead men at the expense of living ones, and who, because there may not be persons in it who stand out from their fellows in as bold relief as formerly was the case, hold that our profession must necessarily be in a state of decadence. There can be no doubt as to the baneful influence of these persons on many, for nothing is so destructive to honest effort as depreciation or discourage-

[1] Thucyd. ii. 40.

ment, or, on the other hand, so healthy a stimulus to effort as a sympathy which is at once hearty and encouraging. There may not be apparent in our profession the commanding personalities, "the Tritons among the minnows," like Cooper, Syme, Crampton, W. H. Porter, and Colles—men who towered aloft above all, like forest trees among shrubs; but this is due not to deficiency of ability, industry, knowledge, or power of accurate and original observation in our ranks, as to there being a far higher standard of professional knowledge, which is aimed at by all and reached by many. "A high education is a leveller," are the words of Sir B. Brodie; but has this upward levelling had a beneficial or a pernicious effect on the progress of surgery? The answer can be best found by pointing to the fact that in the regretted days of the much-lauded and deservedly-lauded heroes I have mentioned, professional knowledge was, in comparison with what it is now, inaccurate and largely empirical, and its progress uncertain, fitful, and irregular. Now, on the other hand, it is advancing steadily, continuously, and with a rapidity which is as amazing as it is unexampled.

It is held by some that in certain of the principal supports on which surgery rests the condition of finality has been reached. I recently listened with deep interest to a surgical address by Mr. Erichsen, whose utterances must ever be regarded with the respect due to one who has aided so signally in raising the standard of British surgery to the high level it now occupies. In dealing with the lines of surgical advance made in our own time he specified operative surgery, surgical precision, and the development of those methods of scientific research which are carried on in the laboratories of the chemist and experimental physiologist. It was to me a matter of some surprise to hear, on the occasion I have referred to, the opinion expressed that the two former of these methods, which may be described under the title of the "art of surgery," have, it was held, like other arts (such as painting, sculpture, and architecture), reached a condition of finality, and that no farther progress need be looked for in any of these directions.

In discussing this somewhat dismal view of the present, as well as the future, of these arts, we should consider the question in a twofold point of view—first, if any analogy exists between them and that which lies more particularly in our own province; and secondly, if there can be any finality in the other arts Mr. Erichsen mentioned. The aims and objects of those he drew attention to appear to me to be, without doubt, as widely different from surgical art as things can possibly be—the first two being essentially imitative, and the third constructive; and though it is hard to conceive a higher degree of perfection being ever reached in painting than the Sistine Madonna of Raphael or in landscape than Crossing the Brook by Turner, or in sculpture than the Venus of Milo the Dying Gladiator, or Thorwaldsen's Hebe, or in architecture than the Parthenon, or the Saracenic palace of the Alhambra, or the Gothic Cathedral at Seville, who can say with reason that finality has been reached in any of the arts of which the works I have mentioned are such splendid monuments? It is true that in these glorious creations the artists have succeeded in deeply touching a responsive chord in the minds of all who contemplate them, and that within the limits of their particular objects, they apparently leave nothing to be desired or looked for; and this result has been obtained in consequence of the great masters who produced them being faithful and earnest students of nature. But are their works indicative of finality? Nature is like an illimitable ocean which changes with every breath of wind and every passing cloud; and from the true artist who makes it—in its ever-varying aspects—his study and his guide, who is animated by the spirit that actuated the great workers of antiquity, may we not reasonably hope that in time, in other of her countless moods and aspects as yet unrepresented and untouched, we may look for works equal to, if not better even than, those bequeathed to us, and which, so long as they exist, must be regarded by those who contemplate and study them with heartfelt gratitude?

Mr. Erichsen illustrates his theory as to the final limit being now reached in surgery by examples drawn from the history of the imitative and the plastic arts, asserting that no art can be carried beyond a certain degree of excellence, which limit once reached no further development need be looked for. But the theory of evolution and development in the history of man, and of the processes of the mind of man, must more or less apply to those arts in which that mind finds utterance, and will be evident in the symbols of successive ages in their infinite variety. No possible advance, he seems to think, can be made, or has been made, in sculpture since the execution of the frieze of the Parthenon, the Venus de Medici, or the Apollo Belvidere; yet when we look clear into the history of this one art we find new varieties of beauty evolving with human perception of spiritual and moral beauty. Even from the Parthenon and Pheidias to that of the younger Attic school—in Scopas and Praxiteles—there is a manifest development, a great step from the period of purely religious art to more human art, which two periods were united by the sepulchral monuments (such as those found in the street of tombs at Athens), of which Dr. Waldstein says:—"There can be no doubt that these works of sculpture bridged over the step from the art of Pheidias to the art of Praxiteles, that they were a stepping-stone from the religious sculpture to that which partook of a more human character."

If we look closely into the history of the other arts, I believe we will find clear evidence of analogous processes of progressive development. The doctrine of finality, for instance, might equally well have been promulgated in the time of Homer, and the view held then that poetry had reached its goal; but the production of the great epic of Greece—well termed the "sun of all ancient literature"—did not prevent or interfere with the subsequent appearance of the imperishable works of Shakespeare, Dante, or Goethe; and true as this is of poetry, is it not equally so of all other arts? But assuming, for the sake of argument, the existence of finality in these arts, and more particularly those indicated by Mr. Erichsen, is there any analogy whatever between them and surgery? I have already indicated some leading differences, but there are others; and chief among them is the fact that the aim and object of surgery are physical repair and restoration of disturbed or lost function to living tissue—tissue the complex nature of which cannot be regarded without awe. Therefore, even if the questionable doctrine of finality having been reached in the arts of painting, sculpture, architecture, or in any other of the arts was well founded, is there ground for supposing from any *a priori* reasoning that this view would hold good of surgery?

If proof were required of the want of finality in operative surgery, as well as surgical precision, I would recall the fact of the unsettled condition of opinion which exists in relation to the treatment of many forms of surgical injury and disease, a condition of unrest which is observable in very many instances that doubtless occur to you; for example, in the treatment of various forms of bone lesion, such as fractures of the lower end of the radius, shaft of the femur, and patella; also in the operative treatment of tuberculous disease of bone and malignant new growths. Why does this surgical unrest continue? Is it not in consequence of our observing that operative efforts are at times attended with disappointing and disheartening results, even when made apparently in the most suitable cases and with all the available care and skill of men in whom natural surgical proclivities and great manipulative dexterity are combined with the confidence derived from long, varied, and well-utilised experience? I might indicate many examples of this; but the instances in which I have witnessed such were chiefly in cases of tuberculous disease of bone, and in operations for certain malignant new growths, notably lingual cancer—a disease which, in truth, seems, in the great majority of cases, an enemy that may be vanquished for a time, but never conquered. Having regard to these vexed points, the question at once comes to the front, If we had anything like finality in either operative surgical treatment or precision in its application, would the condition of surgical unrest I have spoken of exist?

In addition to the essential differences between surgery and the other arts, indicated by Mr. Erichsen, it should be remembered that its functions and objects are not only widely different, but far higher and far nobler than those of any other art. Sir William Bowman, in his splendid address on surgery at Chester, quoted the pious saying of old, that the art of surgery is the "hands of God." The human hands that God permits to be "His instruments of succour to that earthly life and organisation which His power, wisdom, and love having first brought into being, still alone both sustain and cause to perish when their part is played; to that material organisation which dies every hour it lives, which indeed dies by living and lives by dying, and which wonderfully transmits even its own prerogatives and dark secrets to

a succeeding life, destined apparently to remain a marvel and a mystery impenetrable to all generations." What has been the history of the three lines of surgical advance as indicated by Mr. Erichsen? Have we observed in their development that advancement or activity in the growth of any one of them has ever been attended with a corresponding stagnation or lagging behind of the others? There have been times in which the powers and resources of medical science have remained temporarily dormant, and empiricism has in consequence raised its head and reigned supreme, diffusing its blighting influence far and wide—a time when the battle of the orthodoxies and heterodoxies in medicine was as fierce, as irrational, as full of bigotry and dishonesty as it ever was in the analogous mischievous controversies of religion. This pernicious war, with all its senseless din, raged in the schools, until crushed and finally silenced by the unerring artillery of physiological experiment, as elaborated by the ceaseless toil and untiring genius of John Hunter.

Everyone even superficially acquainted with the history of our art is aware that the advancement, development, or strengthening of any one of its three great motive forces, already indicated, has been attended simultaneously with a corresponding advance in the others; and if, as is only too true, biological science has so materially strengthened operative surgery, has this result never been reciprocated, and has not precision in its fullest sense been found to be indispensable to advancement in both? It is, I think, contrary to all probability and experience that in future progress is only to be looked for in one of these three directions. Is it unreasonable to hope that with further developments in antiseptic practice—that boon to surgery for which mankind in all ages to come must ever be grateful to Lister—and which, in our time, has played by far the greatest part in widening the sphere of operative surgery, that regions hitherto barely touched by the operator may eventually become familiar ground for the exercise of his art? From what has already been done by experiment on the lower animals, and in thoracic disease in man—for example, in empyema, pulmonary abscess, pericarditis with effusion, and in vertebral and costal caries,—it is no wild flight of fancy to anticipate a time when a diseased lung may be found amenable to operative treatment. Although brain surgery is still, so to say, in its infancy, we may, having regard to the results already obtained by Professor Victor Horsley, Mr. Alexander, Dr. M'Ewen, Mr. Godlee, and Dr. Roberts of Philadelphia, and when a wider and more accurate knowledge of the localisation of brain injury and disease is obtained, not unreasonably anticipate an era when operations in many such cases may be regarded as well within the region of legitimate operative surgery; and these remarks apply with equal justice to renal, hepatic, and splenic disease. In order to ensure success in these directions we should steadily and fearlessly pursue our course, relying, not alone on biological research, but I should say also on improvement in surgical precision, and advancement of surgery in its operative aspects, and reject the disheartening suggestion that these latter have unhappily reached their *Ultima Thule*—finality. Into the regions where medicine so often has failed to recognise and arrest the progress of disease, surgery advances fearlessly to render aid—aid which happily is often reciprocated,—its followers full of hope, enthusiasm tempered by judgment, and confidence in the coming triumphs of our art.

It should be, and is, a genuine source of pleasure to us all—physician and surgeon alike—that we live in a time when we can view with satisfaction and content the destruction and grim ruins of those anachronistic barriers that in days gone by were erected by foolish men between medicine and surgery, barriers which were in so many ways fruitful of mischief, creating feelings of mutual jealousy and thinly-veiled dislike, and keeping us divided, powerless, and weak. They stimulated a conflict of selfish interests, obstructed the advancement of our common calling, prevented its elevation in public esteem, and in no small degree deepened the cold shade of official neglect. Under the influence of a happy reciprocity and overlapping of our work, aid mutually offered and mutually accepted, by slow but sure steps—steps gathering strength from the irresistible wave of human progress behind them, and guided by those whose undimmed lamps burn with no borrowed light—a sure advance is being made to that goal desired by all—unity in the science of medicine.

The fact that there have been, even in our own time, so many violent vibrations of the pendulum of opinion and practice in medicine and surgery has been often urged against our profession as a reproach. For example, it has been seen to swing from the almost indiscriminate use of blood-letting, to the deprivation from the system of a single drop of blood being viewed with apprehension; from the wholesale use of mercury in the treatment of syphilis to a period when, with more energy than discretion, it was stoutly held to be not only unnecessary, but injurious instead of beneficial, and finally stigmatised as an "accursed drug." Now again the pendulum, actuated by the motive force of common sense, has gone to a great extent back to its former position, and we acknowledge that the error made in the first instance related rather to the mode and time of the administration, and in the quantity that was given. Again, alcohol, in the memory of most of us, was given in febrile and other diseases with a liberality which in the present day would seem distinctly harmful; and among many other revolutions in practice may be indicated the various phases of opinion as regards wound dressing, and also the estimate of the therapeutic value of the operation of trephining. A century ago it was freely, doubtless far too freely, employed, not only as a means of relieving brain pressure, but also as a prophylactic to meningeal or cerebral inflammation. A reaction of opinion then set in, and for operative interference in these cases there was great indisposition. Now the operation has again asserted itself and is warmly advocated, and I believe rightly, in a far wider range of cases of injury and disease than it was at first. This result is doubtless the outcome of improvements in antiseptic practice, and the improved knowledge we have obtained of the localisation of brain disease, though it must be admitted that in this field of medicine we are only on the threshold.

But is there any justification for holding up, as has been done, our profession to scorn in consequence of these vibrations of the pendulum, or rise and fall in the tide of professional opinion? Is it not inevitable that such should occur in the application of a science which, without any reproach, can never be ranged among the "exact" sciences, to an art exercised on all sorts and conditions of men and women, varying in age, occupation, nationality, habits, social status, in wealth, in poverty, in health, and in disease? Again, is the doctrine of change of type in disease one wholly to be rejected? It finds, doubtless, but a limited acceptance among modern pathologists, but, notwithstanding, it is one firmly believed in by many of our more thoughtful physicians, distinguished alike on account of their great experience and exceptional powers of accurate observation. Among these I may mention my colleagues, our late President, Dr. Banks, and also Dr. Gordon, both of whom unhesitatingly accept the doctrine of change of type in disease. Graves, too, in his "Clinical Medicine," speaking of the variations in scarlatina and other diseases, as observed by himself and others, remarks that they "establish the real existence of a change in the constitution of diseases." Some forms of so-called surgical disease, formerly familiar to me in my student days, have disappeared, or are observed but rarely and in a mitigated form. I allude more particularly to the extensive and violently acute forms of syphilitic phagedæna, such as were described so graphically and vividly by that close and accurate observer, Mr. Wallace; phlegmonoid erysipelas, and acute gangrene—cases of which, during my student days, were too frequently the subjects of observation and treatment in the surgical wards of our hospitals; also instances of those often fatal forms of anthrax and cancrum oris, the latter relentlessly sparing no structure, and usually uninfluenced by treatment, however bold, rapidly pursuing its fatal career till checked by death alone. Of such cases little conception could now be formed by the surgical student were it not for the descriptions and illustrations which fortunately survive, and of which latter there are such signal examples in the museum of the Richmond Hospital by Conolly, who, as a faithful and trustworthy pathological artist, has never had a rival.

It is therefore, under all these circumstances, not surprising that there has been so much variation of opinion as well as of treatment, and they show how undeserved are the reproaches to which the profession has been so often subjected, unhappily furnishing excuses for the public being so often influenced by the reckless assertions of an unscrupulous empiricism. Among those whom we find blaming the profession for their frequent "change of front," we find even Professor Humphry, the eminent Professor of Surgery in the University of Cambridge. He has observed: "If the profession is thus liable to be beaten from pole to pole by the changing

blasts of fancy and fashion, it is no wonder that the public are wavering in their confidence, and are capable of being attracted by the bold promises of empiricism under whatever form its head is raised."[2] But still, though we must regretfully acknowledge that there is a strong element of truth in the existence of many such unhappy consequences of much necessary instability in professional opinion, we can always get comfort as well as confidence in the ultimate triumph of medicine by bearing in mind one of the many wise as well as eloquent sayings of the great Nestor of our profession, whom all men revere and delight to honour—Sir James Paget,—who has said: "We may seem to move in circles, but they are the circles of a constantly ascending spiral; we may seem to sway from side to side, but it is only as on a steep ascent which must be climbed in zigzag."[3]

In the preceding remarks I have endeavoured to point out that progressiveness in all the arts, including our own, has ever been synchronous with the development and advance of human knowledge in all other directions, and that this development manifests itself, and will continue to manifest itself, in an infinite variety of ways. Having regard to the fact that the human family may be said to be still young on the earth, the future progress of all arts and sciences is as certain as that "we live, and move, and have our being." We may then feel assured that surgical art will, in all its branches and lines of advance, continue to progress, preventing us ever saying with Alexander, "Our fathers have left us nothing to do." In bequeathing to us so noble an inheritance of knowledge as they have done, the result of their untiring toil and genius, they have left us much to do. It is an inheritance carrying with it not alone a deep responsibility, but one which should make us determine not to let the wheels of progress which they set in motion end in a hopeless deadlock of finality; and also to stimulate an aspiration—one which should be common to us all—to accomplish "something ere the end"; something not unworthy the heirs of those who had—

". . . . That strength which in old days
Moved earth and heaven."

Address

ON THE

VALUE OF EXPLORATORY OPERATIONS IN THE PRACTICE OF SURGERY.

Delivered at the Inaugural Meeting of the Midland Medical Society, Birmingham, on Nov. 3rd, 1886,

BY THOMAS BRYANT, F.R.C.S.,
SENIOR SURGEON TO GUY'S HOSPITAL.

(Concluded from page 913.)

IN cases of purely *chronic obstruction* medical treatment should rightly have the foremost place, so long as no local cause can be made out by a rectal examination; although where acute symptoms are grafted upon the chronic the question of surgical interference should stand foremost, since such symptoms too surely denote changes of a serious nature in the intestine behind the seat of obstruction, and such changes as, if not checked in their progress, will prove fatal. Where, from the history of any given case chronic obstruction is made out, and by a digital rectal examination a stricture is detected, the line of treatment to be adopted is now fairly recognised and carried out. But where, in another case, although the general symptoms are the same, no such obstruction can be felt, and the exact seat and cause of obstruction is uncertain, how uncertain is treatment! The history of the cases may be the same under both circumstances; the existing symptoms may be the same—subacute symptoms of intestinal obstruction grafted upon chronic; and yet, because the finger fails to feel the seat of obstruction or stricture, the whole line of treatment too often becomes uncertain, irregular, and unscientific. Action is paralysed for want of certainty as to the exact seat of obstruction, and for want of action patients die. Is this right? Is it not now in a surgeon's or physician's power to diagnose with considerable accuracy the existence of mechanical obstruction of the large intestine? And, with the diagnosis of this probable fact, is not the surgeon bound, by an exploratory incision into the right or left lumbar region, according to circumstances, to give the patient relief by a colotomy, when from other reasons minor measures are inapplicable? I have no hesitation in saying again what I have said before, that the line of duty points in this direction; that the physician who, with the diagnosis of mechanical obstruction of the large intestine which has given rise to marked and severe symptoms, trusts to enemata and medicine, is trifling with life, and that the surgeon who consents to it is criminal. With this feeling I have on more than one occasion, in these cases, when called in consultation, refused to be a party to a procrastinating practice by going through the farce of further consultation, and of playing a deluding and delusive game, because I felt, as a surgeon, that medical treatment was mere trifling and playing with a life that could probably have been saved; and I regret to say that the result of these cases justified my action. At the same time I entirely exonerate my medical friends from any intentional error. I find fault with them for having too strong a confidence in the means at their disposal, and too little confidence in ours; because they will not realise fully the important physical fact that any force sufficient to overcome mechanical resistance can only succeed by injuring structure, and that injury to intestinal structure too generally means a fatal rupture. The usual report after delay is "sudden death," which means perforation. The most common report after surgical relief has been given late is "death from exhaustion." Where relief by colotomy is given as soon as obstruction becomes marked and troublesome, how different is the surgical record: freedom from pain almost immediately after operation; prolonged life in comparative comfort for months when the local disease has advanced far, and for years when otherwise; whilst, when death takes place, it is not attended with such agony as is commonly associated with that from obstruction, but results from asthenia, brought about, as a rule, by secondary deposit.

And here let me digress for a few moments to bring before your notice what must be described as a marked improvement in the operation of colotomy, which I have adopted during the last two years. I have employed the method in at least twelve cases, and the practice has been followed with most successful results. It is, however, only applicable where there is no great urgency in opening the bowel on account of obstruction. The method is as follows:—Having divided the abdominal parietes—say, in the left groin—with the oblique incision, and exposed and caught the bowel, I bring out by a careful loosening process as complete a knuckle of large intestine as I well can, and fix it *in situ* with two long hare-lip pins with flat heads introduced through the integument forming the lower lip of the wound, then through the whole diameter of the bowel itself, and lastly through the integument forming the upper lip of the wound. I cover the ends of the pins with cork. Even if the intestine be full of faeces or flatus, nothing escapes where the pins are passed. I then wash the whole wound with iodine water, throw in with a puff-ball plenty of iodoform (one part) and boric acid (three parts), finely powdered, into the deeper parts, and stitch up the wound in front and behind the projecting bowel, taking care to leave an opening at the posterior angle of the wound for drainage, into which I insert a tube when the patient is fat, or a strip of iodoform gauze when the patient is thin. I cover up the whole wound with iodoform gauze dipped into a mixture of terebene (one part) and olive oil (three parts), and a good sheet of Gamgee tissue, fixing the whole with an abdominal bandage. On the third, fourth, or fifth day, when the bowel has become perfectly adherent to the outside parts, the pins are removed and the bowel laid open, this part of the operation being absolutely painless. Should the soft parts about the pins ulcerate early, the pins should be taken out. On this account I have in two cases removed them on the second day; in two other cases from the same cause on the third day. In the others they remained four or five days. In no single case did the bowel fall back when the pins were removed, so that it seems tolerably certain that in two days the bowel becomes fixed to the external tissues. By these means I can record the convalescence of a lady aged seventy-five, operated on after ten days' obstruction, in two weeks; the same of a lady

[2] Hunterian Oration, by George Murray Humphry, M.D., F.R.S., 1879.
[3] Inaugural Address at International Medical Congress, 1880, by Sir James Paget, Bart.

aged fifty-seven in two weeks, who, besides long obstruction, had the miseries of a recto-vaginal fæcal fistula; the same of a man aged fifty-six, in ten days, who was operated upon for relief from the agony of an obstruction associated with a large cancerous intestinal tumour; and many others. Indeed, I may say that by this method the operation is made safer and simpler than it was before; and I cannot too strongly urge the adoption of this practice.

I should here, before I leave the subject of intestinal surgery, bring before your notice a case in which an exploratory operation of right lumbar colotomy was undertaken under the impression that relief would be afforded by it, and that the seat of obstruction was lower down. In this surgery was wrong; for the ascending colon, when opened, was found to be quite empty. Nélaton's operation of enterotomy was then performed in the right iliac fossa, with marked relief; the patient, a lady aged seventy-one, dying on the tenth day simply from exhaustion. "I was asked on March 26th, 1886," wrote Dr. Cumberbatch, who was the patient's medical attendant, and the kind author of these notes, "to see a lady in Folkestone aged seventy-one, spare, slight, pale-looking, but fairly healthy. Two days before she had complained of pain in the abdomen, which she attributed to spasms, from previous attacks of which she is said to have suffered. Two days previously she had had a satisfactory action of her bowels. Dr. Lewis, who had seen her, had given small doses of opium and belladonna. When I saw her she had a quiet pulse and normal temperature. There was no vomiting, but an occasional slight retch, apparently more from flatulence than anything else. That evening she came home to London in an invalid carriage, none the worse from the journey. For the next few days she was in much the same state, had no pyrexia or vomiting, only abdominal pain at intervals, with great visible peristalsis, and prominent coils of intestine appearing everywhere. There was no special tenderness in the right or left iliac region. Free enemata brought away nothing, not even flatus. The treatment was 'opium and starvation.' Dr. Wilks and Sir James Paget saw the case with me, and as the symptoms persisted, and it was thought probable that the obstruction was in the colon, colotomy was thought to be the only means of giving relief. For this operation Mr. Bryant was called in on the 31st—that is, on the seventh day of the attack." When I saw her, coils of distended intestine were very visible and peristalsis marked. A rectal examination revealed nothing. The right lumbar region was selected for operation, as it was considered probable that the seat of obstruction was higher than the descending colon. The operation was performed as usual; the ascending colon found and opened, and when opened absolutely empty. Not a stain of fæces could be detected on the finger when introduced. Through the opening in the colon an obstruction was felt in the right iliac fossa. No relief being possible from this measure, it was determined, after discussion with Sir James Paget and Dr. Cumberbatch, that a tense coil of bowel which was prominent in the right iliac fossa should be opened, as in Nélaton's operation of enterotomy. This I did, having carefully stitched the coil of small intestine which presented through the opening made in the abdominal parietes to the edges of the parietal wound before opening the bowel. When the bowel was opened solid fæces escaped, and continued to do so for days with flatus. This escape gave great relief, and the abdominal distension subsided considerably. The patient, however, could never take much food—a very little nauseated her; and although no complications appeared, and the artificial anus became so rapidly established that all the sutures could be removed on the third day, she gradually sank on the tenth day from inanition, but free from pain after the day of operation. After death a necropsy was made by Dr. Goodhart, which revealed such an interesting condition of parts that I publish his report nearly in full:—

"*Volvulus of the Cæcum; Extreme Dilatation of the Cæcum, with Ulceration; Localised Peritonitis; Colotomy in the Right Loin; Enterotomy in the Right Groin.*—Inspection, April 12th, 1886: A lady seventy-one years of age. The body was very spare, but hardly emaciated. The wounds in the right loin and also in the inguinal region were still quite clean cuts, indicating a decided want of proper repair, considering that the operation had been performed on March 31st. The bowel in both wounds was, however, firmly adherent. The wound in the groin had some excoriation around it, as is usual around apertures into the small intestine. On opening the abdomen the abdominal wall was adherent to the bowel at the umbilicus or thereabouts, and again in the epigastric region to the left of the median line, and also towards the left flank, and further examination showed that in all cases the adhesions were to the cæcum, which now filled the greater part of the front of the abdomen, or, to speak more correctly, covered the remainder of the coils with a large flaccid apron or bag. The sac was found to be a much-dilated flaccid cæcum with very thin walls, which tore into a large hole when attempts were made to separate it from the surrounding adhesions. Some of these adhesions were organised and of firm texture; others, that near the umbilicus particularly, were still soft and lymph-like. The remainder of the cavity, as brought into view by turning back the abdominal parietes, was occupied by coils of rather contracted small intestine. No colon was visible anywhere, but on further search it was found in its proper position, nowhere larger than a ring-finger, and in the right loin running into a ring of something beyond which was the cæcum. Turning up the dilated sac of bowel (cæcum), the cæcal appendix was found on the under surface of the upper part of it. The cæcum was displaced from the right iliac region and turned over, so that the caput cæci pointed upwards to the epigastrium, in fact lay there and was adherent, and the anterior surface became the posterior. In addition to this displacement, a considerable twist had taken place at the neck of the cæcum, or in the early part of the ascending colon, which at the neck amounted to a complete revolution, and was only untwisted by turning the cæcum completely round, but which towards the fundus part hardly seemed to be much more than half a turn. The ileum joined the cæcum half way up at its right border, and ran, not, as naturally, to the left, but into the coils of small intestine occupying the right loin. It was not certain how far the displacement may have been aided or determined by it; but running into what now constituted the neck of the twist, above which the parts were dilated, below closely contracted, was a large branch of the ileo-colic artery, that formed a thick cord, which was probably present previously to the fatal obstruction, as a very loose cæcum and a comparatively fixed colon would be a condition of parts in which the fixed colon might form a *point d'appui* round which a twist might very readily have occurred. The cæcum contained a quantity of fæcal matter. The colon below the obstruction held a little milky material, probably the remnant of enemata. If so, it may be interesting to note that it extended the whole length up of the colon. In the colon above the obstruction was some thin brownish mucoid material. The stomach contained five ounces of beef-tea-like fluid. The gall-bladder was distended, and the common duct was very large: probably a gall-stone had passed at some former period. All the other viscera were quite sound, but of the stomach and intestine one would say that it was all remarkably thin, as if atrophied. At the neck of the twist the peritoneum was white and thick, as if the state of parts had been in existence for a long time." From this condition, and from the nature of some of the adhesions which kept the cæcum in its malposition, Dr. Goodhart was inclined to think that there had probably been some chronic distension of the cæcum leading to ulceration of its mucous surface, and that possibly the late symptoms may have been peritonitic rather than obstructive. If not, possibly some slight further twist occurred at the time of the onset of the symptoms which rendered an already partial obstruction complete. Dr. Goodhart considered that death was to be attributed to exhaustion dependent upon the ulcerative enteritis, of which he remarked that he had no doubt whatever, from other similar cases, that it is a very exhaustive and dangerous condition when once it supervenes. I may also state that the opening made at the operation of enterotomy was about one foot from the termination of the small intestine in the cæcum.

This case was doubtless, as Dr. Goodhart described it, one of volvulus of the cæcum, the twisting having been much facilitated by the congenital freedom of the cæcum and ascending colon. The surgery of the case on the whole, I maintain, was right, though only partially successful, since an exploratory operation in the region of the ascending colon gave promise of the best success. This measure was futile, as it turned out, since the bowel was thereby opened below the seat of obstruction. It nevertheless did no harm, and cleared the way for the operation of enterotomy which was performed, with the result of relieving the obstruction, and enabling the patient to die painlessly ten days later.

I would wish my surgical friends to look favourably upon

the operation of enterotomy, since it enables a surgeon to give relief, as in the case just recorded, where no other means are at his disposal. It seems to be applicable to cases of acute strangulation in which the risk of laparotomy is rejected as being too hazardous, or where, on account of the age of the patient, any severe measure must be set aside; to cases of abdominal obstruction in which the clinical evidence points to the conclusion that the obstruction is high up in the large or low down in the small intestine; to cases in which laparotomy is inapplicable and lumbar colotomy is out of court; to cases of obstruction in which relief is urgently required, and a more exact method of giving it is not clear either from some difficulty in diagnosis or other cause. It is an operation that often gets a patient as well as the surgeon out of a perplexity, and is not difficult. I have now performed it four times, and on each occasion as much relief was given as could have been expected.

As a result of an exploratory abdominal operation in a man which, I maintain, failed because it had not been undertaken earlier, I should like to bring before you a case in which I removed a myxomatous lipoma from behind the mesentery which weighed 56 lb. The specimen is now in the museum of the Royal College of Surgeons. The diagnosis of the case before an exploratory abdominal incision was made was not clear, although there was enough to excite a suspicion of the nature of the tumour.

James B——, aged sixty, was admitted into Guy's Hospital, under the care of Dr. Pavy, for enlargement of his abdomen, on October 20th, 1885. His father and mother were dead; the causes of death unknown. The patient was one of a family of four, two of whom were then living, and had always enjoyed good health; one was dead, the cause of death being unknown. There was no history of hereditary disease in the family, nor of tumour in any of the patient's relatives. The patient was a married man, without family. Twenty years previously he had had inflammation of the lungs, and ten years since bronchitis. With these exceptions he had always enjoyed good health. Fifteen months ago he first noticed an increase in the size of his abdomen, the swelling beginning at the lower part of the right side and across the middle line; the swelling was not painful. Ten months ago the patient had to give up work on account of shortness of breath. He was in Ipswich Hospital at Christmas, 1884, and was there punctured twice, but no fluid was found; he was next attended by Mr. Hibberd, of Walton, Ipswich, who punctured his abdomen in five places, but could find no fluid. For about the last four months the patient had had a hacking cough, and spat up a good deal of frothy phlegm. Three months ago he vomited on one or two occasions some material of a "coffee-ground" nature. His legs had lately become very swollen. The bowels had been fairly regular throughout; he had had no difficulty in micturition. On admission, the patient's abdomen was very much swollen, and his legs were highly œdematous. His cheeks were hollow, but his skin looked healthy and red. Temperature 97·4° F. His appetite was good; the bowels were rather constipated. The abdomen, much enlarged and tense, measured forty-eight inches and a half in circumference at the umbilicus. The enlargement was fairly uniform, perhaps a little greater and more prominent in the right lumbar and iliac regions. Its shape varied very little with the position of the patient. The margins of the ribs and ensiform cartilage were pushed up and everted by the enlargement. The abdominal parietes were extremely tense and œdematous. The skin was stretched and shiny, with large superficial epigastric veins showing through it. The skin around the umbilicus was thin and soft for about an inch. The scars of six punctures could be seen, two above and two below the umbilicus in the middle line, and one on either side of it. There was a small lipoma near the angle of the right scapula. There were also masses of fat, defined above, but becoming diffused below, on the inner and upper part of the thighs. Palpation of the abdomen detected little, as the parietes were very tense. On pressing deeply into the epigastric notch, the fingers came down on something hard. A wave of fluctuation could be felt from the middle line of the abdomen to either flank; but it was not well marked, and could not be obtained from flank to flank. There was a tympanitic note over the right lumbar and hypochondriac regions, and resonance also in the left flank. Over the umbilicus and left iliac region there was a peculiar kind of crackpot sound on percussion, suggestive of a hollow viscus immediately underneath the parietes. The respirations were 22 per minute, upper costal in character; the abdomen and lower ribs moved little during the respiratory act. There was hyper-resonance over the front of the right lung to the sixth rib, where the abdominal dulness began. The breath sounds were normal over the front of both lungs. Behind there were dulness over both bases from the eighth rib, deficient entry of air, and muco-crepitations and diminished vocal resonance over dull areas. A troublesome, frequent, hacking cough was present, and small quantities of frothy mucus were expectorated from time to time. The pulse was 64, good. The cardiac dulness existed from the fifth rib and from the left margin of the sternum to the abdominal dulness. The cardiac impulse was felt one inch vertically below the nipple in the fifth interspace. The first sound was followed by a faint systolic bruit; the second sound was normal. The urine was of orange colour, clear, acid, and sp. gr. 1010; it contained no deposit, albumen, blood, or sugar. The patient was put upon middle diet, and for his cough the following mixture was ordered to be taken three times a day: carbonate of ammonia, five grains; ipecacuanha wine, five minims; syrup of tolu, one drachm; water to one ounce. On Oct. 21st the abdomen was explored with a trocar and cannula of fine bore. One puncture was made in the median line rather nearer the pubes than the umbilicus, and another in the left hypochondrium. In the former place the trocar was thrust in about three inches and a half, and its end seemed free as though in a cavity. But no fluid came even with aspiration. In the latter position the trocar was thrust in to its hilt (about four inches and a half), and seemed to pass through something hard and gritty. Only a few drops of blood mixed with oil-globules came out. The oil was supposed to be that used for greasing the instrument before it was used. An ounce of a mixture of compound cascarilla was ordered to be taken every six hours instead of carbonate of ammonia, together with a draught at bedtime composed of ten grains of bromide of potassium and a drachm of syrup of chloral in an ounce of water. On the 22nd, as the bowels had not yet been opened since his admission, he was ordered to take at bedtime ten grains of colocynth and calomel pill, and in the morning an ounce and a half of magnesia mixture, with the result that on the following day the bowels were twice relieved; the stools were liquid, and of a dark-brown colour. On the 24th the abdomen was not quite so tense. A hard ridge could be felt running transversely across the abdomen, three inches below the margin of the ribs; and just below this were some rounded hard lumps. There was a little tenderness on palpation. The abdomen measured forty-eight inches around at the level of the umbilicus, each side contributing twenty-four inches. A cyrtometric tracing showed no difference in shape between the two sides. In the thorax there was dulness behind, and in the axilla from the sixth rib downwards on each side; muco-crepitations and impaired respiratory murmur, vocal resonance, and fremitus existed over the dull area. About 7 P.M. the patient was seized with a severe attack of dyspnœa, and had to sit in a chair, as he could not breathe whilst lying down. He made several attempts to return to bed during the night, but always had to sit up again. The cough was very troublesome, and much tenacious mucus was expectorated. On the 25th the patient was easier, but could not lie down. On the 26th dyspnœa and orthopnœa still persisted. A rectal examination revealed nothing abnormal. I saw the case with Dr. Pavy, and decided to explore the tumour. It was considered that it was probably a soft innocent tumour of myxomatous tissue, or some other variety of connective tissue, probably coming forward from behind the peritoneum. On the 27th the cough was troublesome; the patient could not lie down. An ounce of castor-oil was ordered to be taken at bedtime, and a soap enema to be administered in the morning. On the 28th the purgative acted well. The resonance of the abdomen was now present at only a small area over the liver. The lungs were in the same condition.

Operation.—Chloroform was administered. It was some time before the patient was fully under its influence. He coughed much during its administration. The pulse became weak and irregular during the operation. Two subcutaneous injections of brandy were given. Anæsthesia was maintained for two hours and ten minutes. I first made a vertical incision in the line of the right linea semilunaris, beginning it a little below the level of the umbilicus and extending it downwards four inches. The structures forming the abdominal wall were carefully divided, and all

hæmorrhage was at once arrested by torsion. On dividing the peritoneum a hard mass was exposed, covered by a shining membrane; this membrane was then divided, but the mass within it looked so like large intestine, thickened and matted together, that the membrane was again united and supposed to be the serous coat of the intestine. Another incision, four inches long, was then made, at right angles to the former, downwards towards the iliac crest. The mass first seen still, however, filled the whole wound, and its limit could not be reached in an upward direction, although its lower end was turned out, and found to be lobulated on the surface, and to consist, on section, of fat and fibrous tissue. The incision was then enlarged upwards, so that its upper end was four inches below and to the right of the ensiform cartilage, and its lower end was four inches from the pubic spine. Still the tumour occupied the whole gap. In some places it was connected with the parietal peritoneum by loose cellular tissue, and large veins of the size of a finger coursed over its surface, some of which had to be ligatured and divided at the upper end of the incision. Some omentum and transverse colon appeared in the upper angle of the incision. Whilst the tumour was being manipulated, about thirty ounces of pus gushed out from a cavity in its centre; it was extremely fetid and mixed with blood, and was supposed to be caused by suppuration in the track of a former puncture. By pulling the tumour to the right and drawing the abdominal wall to the left, the tumour was after a while brought through the incision. It had no defined pedicle, but a large attachment to the back of the abdomen by loose cellular tissue, over which the peritoneum was stretched. In the peritoneum were numerous large veins, which were divided between a double ligature. The intestine and liver were all pushed up into the abdominal division of the chest; they looked pale and rather blue. There was no fat in the great omentum. The abdominal cavity was carefully sponged out, and all hæmorrhage arrested. The abdomen was then closed with silk sutures. No drainage-tube was used. The wound was dressed with gauze soaked in terebene and oil next the skin, then iodoform gauze, Gamgee tissue, and finally cotton-wool, the whole being firmly strapped. An opium suppository (two grains) was introduced, and the patient put to bed. Hot blankets and bottles were applied to the feet, the knees were supported by a pillow, and a cradle was placed over the abdomen. The extremities were warm. At 5.30 P.M. the pulse was 76, fairly strong. The respirations were 30, rather shallow. There was mucous gurgling. At 10 P.M. he was in no pain. Pulse 64, good; respirations 30; temperature 98·4°. The extremities were warm. He had a little cough, but could not expectorate mucus from his throat. At 11.30 P.M. he vomited some green bilious material. Ordered a grain of opium pill every six hours. On the 29th he became restless during the night; the pulse quickened but became weaker; the respiration grew more laboured. A tent was erected around the bed, and the steam from a kettle was directed into it. At 11 A.M. the breathing was very bad; loud mucous râles were heard all over the chest. The patient was easier when propped up with pillows. The stomach was distended with flatus. No discharge had come through the dressings. Temperature normal; pulse 104, weak and compressible. At 1 P.M. he was in great pain and distress. An injection of one-sixth of a grain of morphia was administered, and also twenty minims of brandy. In the afternoon he grew gradually worse, breathing only with difficulty. Temperature 102·4°. Ten ounces of brandy had been given in twenty-four hours. The pulse gradually became hardly perceptible, and injections of brandy (ten minims) and of ether (ten minims) were given; but he died at 3.20 P.M., twenty-four hours after the operation. The tumour weighed 56 lb. It measured in diameter twenty-two inches vertically, sixteen inches transversely, and eight inches and a half in the antero-posterior direction. It was composed of huge lobes, of which the principal appeared on the anterior surface, separated by a Y-shaped sulcus, varying from five to seven inches in depth; these lobes and those on the other surface were further subdivided into smaller lobes by more shallow sulci. The tumour was covered with loose cellular and fibrous tissue, and in part by peritoneum, in which coursed numerous large veins. Its substance consisted of large masses of fat and delicate fibrous tissue, mixed together in various proportion, and divided from each other by moderately dense fibrous septa. The pus which escaped during the operation (about a pint and a half) was of a peculiar foul odour, like suppurating hydatid, and mixed with much blood. Under the microscope, blood and pus cells were seen in it, the latter mostly containing globules of fat and much fine granular débris.

Post-mortem examination. — The incision looked very well; the stitches were all in good position. Both lungs were very œdematous, and almost solid posteriorly. Fluid streamed out on pressure. There was much hypostatic congestion; no pus in the tubes, but some emphysema in the anterior part of both lungs. The trachea and bronchi contained a quantity of clear fluid mixed with air. The heart weighed thirteen ounces; there was some hypertrophy of the right ventricle. The abdomen contained about a pint of blood-stained fluid. The inner aspect of the wound appeared to be quite healthy. There were no signs of peritonitis. The stump of the tissue from which the tumour had grown lay in the abdominal cavity. There was no bleeding, and the ligatures were all in good position. This stump consisted of loose cellular tissue and peritoneum, and appeared to be connected with the mesentery. The omentum and gut were quite free. In the mesentery were about eight small fatty tumours (the largest of the size of a hen's egg, and the smallest as large as a filbert); they appeared to consist of fine fat. Behind the peritoneum in the middle line and below the attachment of the mesentery was a large, soft, kidney-shaped, regular tumour, which must have pressed considerably on the vena cava, and probably was the cause of the extreme œdema of the legs. There was a fair amount of fat in the mesentery, but none in the omentum. There was no coagulum in the mesenteric or portal veins. The kidneys weighed 14½ oz. Both the arteries were thick, and the stellate veins well marked. There was a number of minute hæmorrhages on the surface, evidently recent, probably due to change in pressure consequent on the removal of the tumour. The cortex was slightly atrophied, the surface not granular. Both kidneys contained cysts, and in one they were large, the largest being of the size of a Tonquin bean, and consisting chiefly of a thin transparent covering, visible on the surface of the organ. They were lined by a thin fibrous-looking membrane, which could not be peeled off. Their contents were limpid, and not the thick material sometimes seen. Other organs healthy.

Exploratory operations in cases of suppuration of the kidney, in cases of suspected renal calculus, or in examples of growth in or about the kidney, are of somewhat modern origin, the operation being undertaken at first with diagnostic views, and secondly with curative intentions—that is, with the object of draining a suppurative cavity, of removing a renal calculus, or taking away a diseased kidney. And need I add that these exploratory operations have, as a whole, been crowned with great success. As a measure to drain a suppurating renal cavity nothing but commendation can be given; it is but carrying out a well-known principle of surgery, and it is only a wonder that the practice has been postponed until these recent times. The employment of anæsthesia has doubtless had much to do with its introduction, together with the confidence that surgeons now have in their primary treatment of wounds. I was first led to perform this operation by a lumbar incision made as in a colotomy in the year 1870, in a patient of my much-lamented friend and colleague, Dr. Moxon, and evacuated several ounces of pus from a pyo-nephritic organ. The man was much relieved, but died two months later with scrofulous disease of both kidneys. I have repeated this operation at least twenty times, and with excellent success. In half the cases, after the abscess was well drained pus soon ceased to flow with the urine, and the lumbar wound speedily or slowly closed. In four of these cases the discharge continued for so many months, and was the source of so much anxiety, that I at times was led half to regret that I had not taken the kidney away. Yet in all these four cases the wound subsequently healed without the necessity of having recourse to such a severe measure as extirpation of the organ, and the patients are now well and in good health. A little more impatience on my part, or importunity on the part of the patient or his friends, might have induced me to excise the organ. Had I done so, I should have performed four unnecessary operations, and should probably have had to record one at least fatal result out of the four good cases, which would have lowered greatly the value of the measure. In four other cases now living the lumbar fistula is still open; it is, however giving but little trouble, except in one case, in which there is doubtless tubercular disease of the other kidney, as well as of the genital organs. In this case the operation

has kept the man alive for several years. In two cases a urinary fistula exists, one in a lady now aged thirty-seven. In this case it has lasted since 1876, when about three pints of fetid pus were evacuated from her loins, followed by a speedy convalescence. In 1885 she was, except for the fistula, quite well. The second case occurred in 1884 in the person of a widow lady aged fifty, from whom a pint of pus was let out, with immediate relief and a speedy convalescence. The inconvenience was so little in this case that the lady has since married.

I have been tempted to enter a little into detail in these cases of exploratory renal operations in order to show that for a suppurating kidney I have not yet attempted to remove the organ, and believe that such a measure can only be required in very exceptional circumstances. I think my cases demonstrate the expediency, as a rule of practice, of first opening, irrigating, and draining the abscess cavity, and in not being in any hurry to do more; and, secondly, that a urinary renal fistula is not of so troublesome a nature as to justify such a severe measure as renal excision. To know that in addition to one supposed good kidney there is a piece of a second to maintain the balance of health is by no means an unsatisfactory piece of knowledge. It may be added that to catch the urine a mechanical appliance can without trouble be applied. The operation of nephrolithotomy is one that can only be mentioned in words of praise. An exploratory lumbar incision for diagnostic purposes, where sufficient evidence exists of the presence of a stone, is always justifiable; and the question of the simple removal of the stone or of the kidney with the stone is one that can only be solved after the exploratory incision has made the true condition of the parts clear. The success that has attended these operations has been most encouraging; may the records in the future be still better!

Excision of the kidney for tumour disease has not hitherto been a subject of congratulation. I have been tempted but once to make an exploratory lumbar incision down to a kidney, with the view of extirpating the organ should I have found by the incision sufficient encouragement to proceed; but in the measure I was disappointed. Prudence suggested an abstention from the attempt, and subsequent reflection has satisfied me that I was right. The case is, however, worthy of record. It is one of sarcoma of the kidney associated with profuse hæmorrhage, the patient for days losing eight or ten ounces of blood, and then going for months without passing any. I had hoped after my incision to have found a calculus. The size of the veins about the kidney surprised me. On exposing the organ, veins as large as the iliac veins were found almost to cover its surface. A rupture of one of these would certainly have given rise to a fatal hæmorrhage. In removing a kidney for sarcomatous growth, the existence of these enlarged veins must be taken into account, since their presence would add greatly to the dangers of the operation.

Sarcomatous Growth of the Right Kidney, weighing 53 oz., attended with profuse Hæmorrhage; Death from Exhaustion brought about by Hæmorrhage.—Samuel H——, aged sixty, a draper, was sent to Mr. Bryant by Mr. Greaves of Stafford, and admitted into Guy's Hospital, under Mr. Bryant's care, on Aug. 18th, 1885. He was a married man, the father of five children alive and well. He had always enjoyed good health up to seven years before his admission, when he noticed some bleeding from the penis. He stated that he had to hold his urine whilst travelling on the railway, and was in great pain. He then called upon his medical man, who twice passed a catheter, but could not draw off any urine. The patient then went to bed and had a warm water enema, after which a quantity of clotted blood passed with the urine. He kept quiet for some days, and seemed to have quite recovered. Three years later he had another attack of bleeding, and was two or three weeks under the care of a medical man, and he again recovered. Some time after this he was in Birmingham and saw Sir Walter Foster, who carefully examined him and detected an enlargement on the right side of the abdomen. The third and last attack of hæmorrhage occurred on July 10th, 1885, when the patient passed, according to Mr. Greaves, at least eight or ten ounces of pure arterial blood, with great pain, for ten or twelve days. He was then free of pain and hæmorrhage for two days. The pain, when both recurred and lasted until about Aug. 2nd. This illness greatly weakened the patient; but he subsequently had no bleeding, his urine appearing, as usual, normal. On admission on Aug. 18th, he was blanched and feeble from loss of blood. There was a swelling in the right lumbar extending into the umbilical region, which moved up and down with the diaphragm. Dulness on percussion could be felt about one inch below the margin of the ribs, extending towards the middle line one inch from and half an inch below the level of the umbilicus. There was no fluctuation on touch. The tumour could be moved between the hands. The veins of the right side of the chest and abdomen were more distinct than those on the left. Urine: sp. gr. 1020; acid; gave a trace of albumen. The patient was ordered milk diet, and ten grains of colocynth and henbane pill at night, with a magnesia draught in the morning and a simple enema to prepare him for the operation. On Aug. 21st the urine was of sp. gr. 1020, acid, with a trace of albumen and blood. The patient was put under chloroform. Mr. Bryant made an oblique incision five inches long from the middle of the crest of the ilium to the erector spinæ muscle. Some vessels were ligatured, and a director was passed. After the tissues were cut through, he came down upon some very large veins which were embedded in the fat around the kidney. They were as large as the index-finger. The part about the kidney was then punctured with a trocar and cannula, but no fluid was drawn off. The swelling was clearly a solid growth, and could not be removed. The wound was accordingly stitched up and dressed with iodoform gauze. By this exploratory operation it was clear that the patient had a large sarcomatous growth in his kidney. On the 24th the wound was dressed. The patient seemed fairly well, but had pain in the right thigh. Hot fomentations were applied. The urine had a strong ammoniacal odour, and was alkaline, its specific gravity was 1025, and it contained blood. On the 25th the patient complained of pain in the hypogastric region and of difficulty in passing urine. A No. 9 catheter was used, and seven ounces and a half of urine were drawn off. The pain in the thigh was less. The wound was looking well, iodoform and powdered boric acid being applied to it. The specific gravity of the urine was 1020, and contained blood. On the 28th the patient was very weak, and felt very drowsy at times. His temperature was high (*vide* table). The patient died at 3 A.M. on Aug. 29th.

Necropsy.—The right kidney was large, irregular in shape, and filled up the whole of the right side of the abdomen. It weighed 53 oz. On section the upper part was found to be yellow and caseating, with oily masses; the lower part was nodular, with recent hæmorrhage into cysts. The left kidney and other organs were healthy. Their weights were as follows:—Left kidney, 7 oz.; spleen, 7½ oz.; liver, 47 oz.; heart, 11 oz.

Time reminds me that I must now bring my remarks to a conclusion, otherwise I could have illustrated the advantages of exploratory operations in diseases of the thorax, bladder, and even from the surgery of the cranium and its contents. In this latter class of cases, however, my words would have been on the side of caution, for it has not yet been actually proved, as some would lead us to believe, "that it has become possible, by the observation of symptoms, not only to determine the fact of the existence of some morbid growth within the skull, but also to determine its precise position with such accuracy that it can be cut down upon and removed." It is not yet proved "that the necessary operations can be performed by the aid of certain precautions, with a very small degree of risk to life, and that considerable portions of brain may be removed without injury."[1] What has been proved is that in *exceptional* cases a diagnosis of the position of a tumour can be made with sufficient accuracy to justify a surgeon in cutting down upon and trephining a skull to search for the tumour with a view to its removal, but no more. It is to be hoped that these cases may become more numerous, but at present, if we are to be guided by facts, the surgeon must not be too bold or too sanguine. I should like my hearers to read upon this subject an able paper drawn up by my young, but able, colleague, Dr. Hale White, and published in the volume of the Guy's Hospital Reports for 1886. It contains an analysis

[1] The Times, Aug. 17th, 1886.

of 100 cases of cerebral tumour, with reference to operative treatment, cause, mode of death, and general symptoms. A careful study of this paper will probably give ballast to any judgment which might otherwise possibly be over-stimulated by some brilliant success.

By way of summary, I think we may take it as proved that in surgery exploratory operations made for diagnostic purposes should in certain cases be systematically employed, and that in tumours of the breast and testicle the value of this practice is best illustrated; that such exploratory operations are most valuable when they lead up to treatment, as in cases of acute strangulation of the small intestine from whatever cause, and in those of deep-seated abdominal suppuration.

In conclusion, gentlemen, allow me to thank you for the kind attention you have given to my address. The subject I have brought before you is, I am convinced, well worthy of your consideration; and if I have failed to carry you with me in all my statements and arguments, I trust I may have excited sufficient interest in the subject to lead you to think it out for yourselves, when I feel tolerably certain that we shall eventually accord.

TRACHEOTOMY IN CROUPOUS DIPHTHERIA.

By GEORGE BUCHANAN,

PROFESSOR OF CLINICAL SURGERY IN GLASGOW UNIVERSITY.

AT the meeting of the International Medical Congress in London in 1881, I brought before the members the importance of tracheotomy as a means of saving life in certain types and stages of diphtheria. Subsequent experience has confirmed my conclusions. Since that time I have not operated so frequently as in previous years, but my success has been more uniform. I believe I can now more readily than formerly select the cases which ought to be operated on from those where the operation is unjustifiable. It brings discredit on a useful proceeding if a surgeon undertakes it simply to give a child a *chance of life* when other treatment has failed. There are some conditions in which tracheotomy affords a very fair prospect of saving life when a child is obviously dying; there are others in which the operation is simply cruelty, without any hope of doing good. The points to be attended to in the diagnosis of suitable cases, and the precautions to be adopted during and after the operation, are so concisely stated in the paper referred to, that I have no reason to recapitulate them here; but the reader may refer to "The Transactions of the International Medical Congress," 1881, vol. iv. (Diseases of Children), p. 207. The following case illustrates every one of the particulars in the paper. It was the case of a patient of Dr. Crawford of Uddingston, who has carried out the after-treatment in three of my successful operations of tracheotomy for diphtheria.

Catherine B——, aged two years and seven months, was seen by Dr. Crawford on the evening of Sept. 23rd for a supposed attack of croup. The child, who had been out of doors the previous day, was seized at 4 A.M. with a croupy cough. The parents had considerable experience of such attacks in other members of their family, and they followed out their accustomed method of treatment, but as no improvement took place Dr. Crawford was sent for in the evening. At this time there was some stridulous breathing, and the tonsils were covered with diphtheritic patches. Dr. Crawford learned that the child had been more or less ailing for eight days, with want of appetite, restlessness, and soreness of the inside of the mouth, causing disinclination to take food, but no tendency to cough till the day mentioned. As soon as Dr. Crawford saw the case he recognised it as one of great gravity, owing to the rapidly increasing stridor and ringing cough, with occasional laryngeal spasms, and he intimated that if no relief came before morning the danger of suffocation would be imminent. In the morning the child was no better, and I was sent for and reached Uddingston at 12 o'clock noon.

I found the child feeble, restless, and feverish. The tonsils were covered partly with false membrane, and partly with unhealthy-looking matter from little ragged ulcers. The breathing was laboured and stridulous. On exposing the naked body of the child (a most important method of diagnosis), the efforts at inspiration were seen to be sufficiently powerful to drag in the more elastic parts of the chest walls—the ensiform cartilage, the intercostal spaces, and the hollows above the clavicles and between the sterno-mastoids. The chest percussion was clear, and the air was evidently entering the lungs so far as it could gain admission. There were no moist rales or any indication of implication of the smaller bronchial tubes; in fact, the signs pointed to a thirst for breath, a strong attempt at in-suction, and a diminished aperture of entrance in the trachea; but the child was much exhausted, cold, and depressed. I told the parents that Dr. Crawford and I had no doubt whatever that the child could not live twelve hours; that its weak state would make the operation somewhat hazardous; but it was just such a case as might probably be successful, and certainly the child would be for a time free from its struggles and distress. The parents urged me to endeavour to save its life.

The child was placed on a table near the window, with its head leaning over the edge of a pillow, so as to extend the neck. Dr. Crawford carefully gave chloroform. I made an incision from a little above the episternal notch about two inches in length, and repeated the cut several times in precisely the middle line, till I saw the white rings of the trachea. The isthmus of the thyroid gland came into view, as also a large bulging vein on the right side of the incision; but these were easily held aside by a blunt hook. There was no hæmorrhage. I here wish to state that I continue to practise the precaution I have stated in all my papers since my early experience: I never open the trachea till bleeding from the wound has been arrested. I know that this is not the teaching of many, but I also know from experience that the opposite teaching is wrong. In my early days of operating I was once urged by the medical attendant of a little patient in a case where there was bleeding and the blood dark and viscid, and where I was proceeding to check hæmorrhage, to plunge my knife into the trachea. I was told that the admission of air would relieve turgescence and check bleeding, and I yielded. But the blood trickled into the wound, caused coughing, failed to check hæmorrhage, and the operation was not successfully completed. I shall never a second time expose myself to this experience, which is now twenty years old. I take Trousseau's maxim: "Operate slowly, very slowly." See what you are doing, and hook up the clear white trachea with a hook before you use the knife.

This having been done, I plunged the knife into the trachea as far up as the hook, with its edge downwards, and made a cut half an inch long. I have read and heard directions to cut upwards, but I never do; I clear as much of the trachea as I wish to cut, and I cut no more. There is no danger of cutting anything you ought not, if the trachea is cleared and held up in view, to the extent of the incision to be made. I would strongly urge the observance of this rule on young operators. Tracheotomy in the living body of a child is a very different thing from the same operation on the dead body. It is to be remembered that the trachea of a child three years old is a very small tube, that it is in constant movement, and that at the operation it lies at the bottom of a comparatively deep wound; or rather that as soon as the incision goes through the superficial fascia the wound gets filled up with fat and pouting cellular tissue, often turgid veins bulging from the sides. Not unfrequently the thyroid gland invades the wound from above, though that can be held up with a blunt hook; often I have notched it, and sometimes divided the isthmus, tying whatever vessels required it. Not unfrequently the apices of the thymus gland protrude into the wound from below. All these obstacles, when they present themselves, must be held aside, and the clear rings of the trachea brought into view and held so till the opening is made. Use a thin sharp knife, and make a the opening is made. Use a thin sharp knife, and make a clean, quick plunge into the trachea. Avoid tracheotomes and other devices often advised as substitutes for the surgeon's hand. Anything else than a thin sharp knife is apt to push aside the trachea and pass beside it into the loose areolar tissue. If the space below the thyroid isthmus seems too limited, clear it away or divide it, and extend the cut up to or into the cricoid.

As soon as the trachea was opened to the extent of about half an inch or rather more, I put in a dressing forceps and opened the blades, when instantaneous relief occurred. A violent cough expelled a quantity of mucus and false membrane, and pre[illegible]thing with perfect

calm. I held the tracheal incision wide open for some minutes, occasionally irritating the back of the trachea with a probe to cause a fresh cough, which had the effect of bringing out some more shreds of membrane. Finally I introduced a small silver tracheotomy tube, and secured it with tapes round the child's neck, after which the child woke up from the chloroform with a peaceful smile, and was placed in bed, breathing easily and quietly. As a rule, I now use the old-fashioned silver tracheotomy tube, with an inner one to remove for cleansing. If the case is going to do well, as will be indicated within the first twenty-four hours by the secretion being loose, muco-purulent, and copious, it does not matter what the tube is, and the simpler the better. If it is going to prove anxious and doubtful, as evidenced by the secretion being viscid, tenacious, inclined to dry and block up the tube, indicated by the well-known whistling sound in the tube, then any complication in the construction, as splitting or jointing to facilitate introduction, just offers so many points to which the viscous fluid adheres and soon becomes converted into a tough obstructive pellet.

The parents were instructed how to keep the tube clear. Nourishing food, milk, and soup were ordered; a plentiful supply of fresh air in the room was secured by causing the fire to be kept blazing, but not too warm, and the window to be kept open at intervals, the child being protected from a draught by a screen placed between the window and the head of the bed.

I have long ago given up the practice of keeping the child in a steam bath by a jet of steam from a kettle or other utensil, introduced under curtains arranged like a tent over the bed, and I am quite surprised to see in some places "tracheotomy cots" with tents over them for this purpose. I am perfectly certain that fresh air, properly heated by an open fire, is far more refreshing for the poor little child than the kind of atmosphere which exists within one of these tents. Even the attendants cannot remain very long within the curtains without coming out for a breath of fresh air. Theoretically, air moistened with steam is better for the lungs than dry air. Practically, I have found that warm fresh air gives better results.[1] If the secretion tends to become viscid and dry, the amount of moisture produced by steam from a kettle or boiler diffused through the surrounding air is of no avail to soften the plug. But I have found that this can be accomplished in part by placing over the mouth of the tube a bit of honeycomb sponge wrung out of hot water, and for the removal of the pellet a soft feather dipped in tepid water used as a mop to brush out the tube; this I have often known to be of great service in removing tough pellets. The whistling sound to which I have alluded causes anxiety from quite another source—viz., it is almost always caused by fresh inflammation, dryness, and viscid secretion further down the trachea; in fact, it may be looked on as evidence of spread of the disease from the trachea down into the bronchiæ. I have known a number of cases where recovery took place after this whistling sound was heard, but it always causes me the greatest anxiety.

In the case here related the recovery was uninterrupted and rapid. The tube was kept in as a precaution for eight days, and thereafter convalescence was rapid. I have now performed tracheotomy over sixty times with the result of saving the life of one out of every two and a half operated on; and the proportion of cures to operations has risen during the last half of my cases, owing, I believe, to rigid attention to the diagnostic signs alluded to in this paper.

Glasgow.

ACUTE RHEUMATISM COMPLICATED BY A BULLOUS RASH (PEMPHIGUS?).

BY F. L. BENHAM, M.D., B.S., M.R.C.P.

THE following is a curious and, I believe, rare example of a somewhat unusual form of skin disease, occurring in the course of rheumatic fever, and apparently a part of the disease.

G. G——, aged twenty-five, a man of short stature and not very robust constitution, had had an attack of rheumatic fever four or five years ago, which lasted five or six weeks, and had left some disease of the mitral valve. He had remained well ever since until the present illness. He had been ailing for the previous week or two, but had gone to his work in the City every day as usual. On returning home from work on Saturday evening, March 21st, 1885, the weather having suddenly become cold and wet, followed in the night by a fall of snow, he complained of pains in his limbs and became feverish. The pains got rapidly worse; he grew very restless, and went to bed, but could not lie there long together, preferring frequently to sit up, owing to severe pain in the back. This state continued much the same for the next three days. He was sleepless and even delirious at night.

The man was first seen by me on March 25th, and was then found in a state of active fever, with intense pain and distress. Temperature 102·5°; pain and swelling of all the joints of the limbs; copious perspiration; no rash on the skin, except some spots of acne on the face. A slight mitral systolic bruit was present. He was ordered to lie between blankets, and, after a purge of calomel and jalap, to take a mixture containing twenty grains of salicylate of soda and fifteen grains of bicarbonate of soda every four hours.—March 26th: Bowels had been moved once. Patient slept better last night than before, and was not delirious. Arthritic pains much less, and the perspiration very profuse.—27th: Temperature 101·4°. Rheumatic pain and swelling of the joints almost gone; copious sweating, especially on the face. A peculiar eruption has appeared, consisting of large, pale, soft, blunt, conical papules, the size of large peas, situated over the pectorales, backs of hands, inner sides of knees, and above the ankles. On the first appearance of the rash it bore much resemblance to urticaria, but the wheals did not vanish and reappear. Instead of this they were persistent, and gradually became broader, flatter, less raised, and bright red; it might now be called erythema papulatum, extensively distributed. To repeat the powder and mixture every six hours.—28th: The rash has spread all over the body; many of the oldest papules have become broader and flatter, the size of shillings or florins; the largest had quite subsided in the centre, the skin there being normal and surrounded by a more or less perfect raised red ring. The eruption was accompanied by a good deal of itching. Over the lower lip were patches of closely set vesicles like herpes; there were also large vesicles on the pinna of the right ear, and a very large bleb, nearly the size of a pigeon's egg, over the right elbow (patient lay chiefly on his right side); the rash was very abundant over the back, abdomen, and thighs, down to the knees and even below, but has quite disappeared from the backs of the hands. Temperature 101°. Tongue thickly coated. Rheumatic symptoms had quite left the joints, and the patient had slept bettur.—29th: In the same condition. No fresh papules, but more vesicles, large and irregular, on the face, especially the forehead. They had no inflamed base, and the contents were clear yellowish serum. On the trunk the red discs had come to form slightly raised narrow red rings, and often coalesced to form circinate shapes (erythema annulare and gyratum). The itching, which had been troublesome all along, was now less.—30th: Temperature normal, no articular rheumatism remaining. There were some large irregular low bullæ on the summits of the larger papules over the buttocks &c.; a few more vesicles on the face, others drying up, but none changing into pustules. For the next few days, subsidence of the rash slowly went on.—April 1st: Salicylate of soda replaced by mixture containing quinine and arsenic. The tongue became cleaner, though the bowels were always confined. Some solid food was allowed.—4th: Vesicles drying up; some burst, leaving superficial sores, which formed the patient's chief discomfort. The general eruption was reduced to a mere roseola, but a large bulla remained for several days at the umbilicus, and there was a vesicle on the side of the tongue. A slight return of the rheumatism took place in the finger-joints of the left hand.—6th: A fresh crop of large irregular blebs appeared yesterday, and to-day on right thigh and knee and left buttock. Patient feels very weak. Temperature 100°; tongue clean; bowels confined—7th: Slight return of rheumatism. Salicylate resumed.—13th: Temperature normal; tongue clean again. Some more blebs on thighs, and sores still remaining on buttocks.—20th: A few small blebs have come out from time to time, especially over the thighs; sores on feet and buttocks slowly healing. The patient was now practically well, and was able to walk as soon as the sores healed. Saline aperients were given for some time, on account of constipation; and meanwhile he recovered strength. There appeared to be no increase of the valvular disease during the attack. He remained well for some months, and then had another slight attack of rheumatism.

[1] Vide Dr. Rank[illegible]ress, 1881.

Remarks.—The interest of this case lies chiefly in its rarity, no description corresponding to it being found, as far as I know, in works on medicine, either under the headings of "acute rheumatism" or "cutaneous diseases." The best account, I believe, is in Trousseau's lecture on Erythema Papulatum; but in the cases there narrated the rheumatic symptoms were slight and subsidiary to the eruption; in them, also, the eruption was less extensive and less severe, though he speaks of vesicles being sometimes developed on the top of the papules. Though in this case, unlike those of Trousseau, there was nothing like erythema nodosum present, yet it shows the intimate connexion between E. papulatum and rheumatism, and, moreover, the metastatic character of the skin affection, which alternated with the articular symptoms. The special feature to be observed, however, is that, besides the ordinary phases of development which the erythematous papules passed through, in this case it was the rule for them to pass on to distinct well-formed bullæ, having all the characters of pemphigus. Why should the case, therefore, not be regarded as one of acute pemphigus, in the existence of which Hebra disbelieved? Or if authorities on skin diseases (delighting in endless distinctions) object to this identification, perhaps the most appropriate title for it would "erythema bullosum," as a variety of erythema multiforme. Lastly, it may also be noticed as a somewhat uncommon feature of acute rheumatism that the symptoms set in suddenly with great severity, there being delirium (if the account given by the patient's friends is correct) on the very first night of the illness.

Note.—Since writing the above, I have come to think that the case might be reckoned as an instance of Bazin's "hydron," though the symptoms do not exactly correspond; but I should regard it, all the same, as a species of erythema multiforme.

Elizabeth-street, Eaton-square, S.W.

A PRACTICAL HINT ON THE PERFORMANCE OF TRACHEOTOMY.

By W. LEONARD BRADDON, F.R.C.S.E. (EXAM.)

UPON looking through various text-books and articles upon this operation I can find nowhere any insistance upon the following detail—one important, as I believe, at any rate to operators of not large experience, and valuable, as increasing greatly the facility, and therefore the success, of the operation. The operator is usually recommended, standing preferably on the right side of his patient, after first determining the exact relation of parts, to fix the trachea with the left hand, the fingers on one side and the thumb upon the other, at the same time stretching the skin at the site of incision. The direction is at least distinct, but the manipulation is usually in effect very different. In all of many cases which I call to mind there has been a little (the only) trouble in the operation, and in some, considerable danger, delay, or anxiety, consequent upon the way in which the attempt is made to keep the windpipe steady, as customarily taught and performed: four fingers on the left side and the thumb upon the right side of the larynx press with more or less force immediately backwards to hold the organ in place, with the effect of considerably aggravating the dyspnœa (especially if an anæsthetic is not being employed), of flattening the pipe against the vertebral column to some extent, of in all cases increasing the depth at which the part to be incised can be reached, and frequently of failing to secure fixity of the larynx, which, likely to move with the slightest change of pressure, is pushed still more out of reach by the increased pressure made to secure it. Any or all of this inconvenience is the result of pressing backwards with the fingers placed upon the skin immediately on either side of the windpipe.

The suggestion I have to make, and which, I have no doubt, many surgeons have long ago thought of or adopted, although hitherto I have never seen it noticed, is so simple as to provoke a doubt as to its value, but anyone who tries it will, I think, find it so effectual in practice as to have no more doubt than I have as to its advantage. Let the surgeon place his left hand, as widely expanded as possible, over the neck of a child in the position for tracheotomy; then resting the fingers upon one and the thumb upon the other side firmly upon the skin, as far to the side of the neck as they will reach, gradually draw in the thumb and fingers, and the skin (and loose tissue underneath) with them, towards the median line: as the sides of the windpipe are approached, a little more pressure, made in a backward direction, will place the ends of thumb and fingers in a position in which they almost meet behind the larynx, which is thus firmly held by the encircling hand in a position in which all the great bloodvessels &c. (which *have* been wounded) and the vertebral bodies (which, it is recorded, have *blunted a knife-point*) are far out of harm's way, the windpipe itself starting forward and standing out prominently under the skin, which is yet fairly stretched (and can be stretched more tightly) over the site of incision, and lying both as superficially as could be desired and as perfectly under control as possible. Lastly, and this I think is not altogether unimportant, this procedure may be adopted without producing more than the very slightest degree of discomfort in any ordinary child—the younger the more easily; and one is still able to make the skin as tight as possible; now, however, the necessary pressure is distributed all round, instead of acting directly backwards upon the tube so as to flatten or displace it. I have even been able without much trouble to make the thumb and fingers feel each other behind it by this means; while by the older method I have seen the production of undoubtedly a dangerous increase of dyspnœa. I may have overrated the danger, or underrated the utility of the usual method of fixation, but it has always seemed to me to be the only difficulty in an operation, which of course has none for experienced surgeons, but to others presents often some trouble, chiefly in consequence of the fact that the means adopted for fixing the part to be incised, being ill-devised though time-honoured, are not only not to be relied on to secure that end, but, as I have tried to show, they directly tend to increase the depth of the wound of the trachea from the surface and the distress of the patient; and in all the accidents I have read of, and some that I have witnessed, this method has shown itself marked sometimes by danger, often by inutility. As to the barbarity of the *hook*, is it not an insult to the fingers of the χειρουργός?

REMOVAL OF SUPERFLUOUS HAIRS BY ELECTROLYSIS.

By JAMES STARTIN,

LATE SURGEON AND LECTURER AT ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN; CONSULTING SURGEON TO THE SHEFFIELD PUBLIC SKIN HOSPITAL.

UNTIL the last two years, in England the removal of superfluous hairs from the face has been an unsatisfactory operation. Superfluous hairs that grow on the face, upper lip, and chin of women, and sometimes on the noses of men, are always a source of annoyance, and very naturally they desire to have them removed.

In the summer of 1884 my attention was turned to the removal of superfluous hairs from the face by reason of several cases coming under my notice, the patients in most instances complaining of the very unsatisfactory results obtained from the use of depilatories. In the autumn of that year, in answer to an inquiry in THE LANCET,[1] I recommended the process of destruction by electrolysis, having then had several successful cases. In consultation with my friend, Dr. W. Kilner, electrician to St. Thomas's Hospital, I devised the apparatus required; that is, I had made for me by Mr. Groves of Bolsover-street, a nice portable case containing a small twenty-cell bichromate battery, which can be regulated to three powers at will, two ordinary sponge electrodes, two yard-and-a-half wire conductors, and a needle-holder, devised much like an ordinary pen-holder. I found after considerable trial, that toughened gold, well sharpened, was the best material, and wore the best.

Now with regard to the operation. The application of the needle electrode cannot be made without more or less pain, varying much in different patients, no matter how the sponge electrode is applied. I then, after a prick or two of the needle electrode, brush over the part a 5 per cent. solution of hydrochlorate of cocaine, with good result, almost invariably deadening the pain. In one or two instances I

[1] Vol. II., 1884, p. 715.

have had an anæsthetic administered, but I find this is seldom necessary, as the pain is slight. The operation can now be proceeded with. The negative needle electrode is plunged into the root of the hair for about one-sixteenth of an inch, and the positive electrode sponge is applied in the immediate neighbourhood. The needle should be kept in for about the space of five seconds, then the sponge electrode should be removed and afterwards the needle electrode. To know that the operation is effectual the needle should produce slight frothing of the tissues. The hair destroyed can now be easily epilated with an ordinary pair of dressing forceps, and it should come out without the slightest adhesion. This operation applies more especially to hairs that are noticeable to the naked eye. Fine downy hairs can always be destroyed by the application of a properly made depilatory. A slight inflammation of temporary character occurs for an hour or two after the operation in the destroyed follicle; this can be controlled by the use of a soothing lotion. The operation, if carefully done with a battery in good working order, is invariably successful, especially if the hairs are few and of good size—from a quarter to half an inch long. If many hairs have to be removed, then several sittings will be required at intervals of about ten days. A hundred hairs can be removed at a sitting. The following cases may serve to illustrate the operation.

1. A young woman, aged thirty-two, consulted me on March 15th, 1884, with superfluous hair on the upper lip and chin; she had pulled them out herself, and there remained about a hundred short, dark, stumpy hairs. I removed in two sittings as many as I could see; for the removal of the remainder I prescribed a depilatory for her to use. I recently saw this patient, showing the result of the operation to be successful.

2. In August, 1884, a young lady, aged thirty, was sent to me from the north of England, who had had a superfluous growth of hair on the upper lip and chin for about five years. I removed all I could see in two sittings. I heard recently that the operation was successful.

3. I removed a patch of superfluous hair from the neck of a young lady last August, and I received a letter from her mother last week to say the operation was successful.

4. In October a young woman came to me to have a large quantity of hairs removed from the chin and upper lip. This was the worst case I have had, both from the numbers of the hairs, their depth of growth, and the extreme sensitiveness of the patient to electricity. I used the electrode with difficulty after painting the skin with a 5 per cent. solution of hydrochlorate of cocaine, and could only remove about fifty at a sitting. After seven sittings I have nearly accomplished their removal.

5. A gentleman consulted me in the summer of 1885 for a few superfluous hairs on the tip of the nose. I removed these at one sitting, the result being successful.

6. In July, 1885, I removed about fifty hairs an inch in length round the nipples of the breast of a young woman, also some from her upper lip. One operation proved successful.

Since I wrote this paper I had the honour to show my battery and electrodes in the museum, and demonstrate the process in the Surgical Section to the President and members, at the meeting of the British Medical Association in August last, in connexion with the destruction of the lupus nodule, moles, warts, and nævi, in a paper on the "Surgical Treatment of Lupus and Acne" I read at Brighton.

Sackville-street, W.

NECROPSY OF A CASE OF MYXŒDEMA.

By GILBERT BARLING, M.B., F.R.C.S.

By the courtesy of Dr. Suckling I had the opportunity of examining the body of a patient of his suffering from myxœdema. A clinical note of the case has been reported by Dr. Suckling in THE LANCET of May 15th, 1886.

The necropsy was made thirty-six hours after death. External appearances: The body of a very stout old woman; the lower lip much everted and swollen; cheeks of a bright-red colour; a well-marked arcus senilis. The legs, face, and arms pitted on pressure, but no fluid could be made out in the abdomen. Incision into the tissues did not reveal the mucoid appearance mentioned in other cases. Head: The cranial bones were very thick, especially in front, there reaching to nearly a third of an inch. The brain and its membranes presented no abnormal appearance. Weight of brain 2 lb. 10 oz. The pituitary body was reserved for microscopical examination, but no change was subsequently found in it. The cervical sympathetic showed no change to the naked eye, but it was not examined with the microscope. The thyroid body was small, especially the right lobe, and it was very tough to the feel, and so intimately blended with the cervical fascia that it was difficult to separate the two exactly. The weight of the organ was 155 grains. Microscopic examination showed a simple atrophy of the gland structure—in some places complete, in others only slightly advanced. If a fairly plump lobule were examined, it showed at its periphery the remnants of atrophying capillaries; next to this a zone in which the capillaries had not undergone marked change, but the meshwork formed by them, enclosing the alveoli, had lost its epithelial lining, as well as the colloid material found inside. In the centre of the lobule, capillaries, epithelium, and colloid material appeared in the relative proportions found in health. There was nothing to indicate that the disappearance of gland tissue was due to a formation of granulation tissue resulting in a cirrhosis. The submaxillary glands weighed one ounce. No abnormal condition was found in them either by the unaided eye or with the microscope. Thorax: The lungs were crepitant throughout, and presented a few caseous and calcified nodules scattered sparsely through them. The heart weighed fourteen ounces, and there was marked hypertrophy of the left ventricle. The valves were fairly healthy, but there was considerable atheroma of the aorta. Abdomen: On opening this cavity several ounces of glairy but clear fluid were found. Some of this collected and boiled became practically solid in the test-tube. The liver was adherent to the stomach, its capsule was much thickened, and microscopic examination showed a slight cirrhosis in places advancing from the surface. The gall-bladder was distended with about four ounces of pus, the cystic duct being plugged with a calculus which was solitary. Kidneys: The pair weighed ten ounces; the capsule was thickened and adherent, and the cortex rather narrow. Microscopic examination showed a moderate amount of interstitial nephritis. The spleen was firm and dark, and weighed three ounces.

ST. BARTHOLOMEW'S HOSPITAL.

DISEASE OF THE KNEE-JOINT, SECONDARY TO SYNOVIAL CYST; AMPUTATION.

(Under the care of Mr. THOMAS SMITH.)

THE following case is one in which acute arthritis followed the formation of a large synovial cyst of the kind to which special attention has been drawn by Mr. Morrant Baker. Independently of the rarity of the case, the condition of the knee-joint, as found after removal, is of considerable clinical interest. Before amputation there was no swelling along the track of the cyst (which had been previously drained), the swelling of the joint was not excessive, and the temperature was normal. The extensive disease of the joint at the time of amputation was only foreshadowed by the excessive pain experienced by the patient on the slightest movement of the limb or even jarring of the bed; he was in a constant state of terror, unable to sleep, and begged for the removal of his limb. For the following notes we are indebted to Mr. H. E. Knight, dresser to the case:—

A. B——, aged forty-five, bootmaker, was admitted into Henry ward on August 2nd, suffering from a swollen left knee-joint. In June, 1885, he was in the hospital, and a synovial cyst of Baker (supposed before opening to be an abscess) was opened in the calf of his left leg; about one

pint of clear synovial fluid was evacuated from it. This was done under antiseptic precautions, and the wound healed by first intention. He was discharged at the end of a month with his leg in a Martin's bandage, at which time there was no sign whatever of any disease of the knee-joint, neither had the cyst refilled. In December he came back again as an out-patient, and had a back splint applied, as he complained of pain in the knee, and this relieved him. In May, 1886, the patient took off the splint for two months, and then the knee began to get bad. The splint was again applied, with great pain to himself, and he came into the hospital. Family history good.

On admission, the left knee was much swollen and very tender; there was no heat or redness of the joint. The following measurements were taken: Round left knee, 13in.; round right knee, 12in.; above left knee, 11in.; above right knee, 12in. He says he has sharp shooting pains in the joint at night, which last for about three minutes and then subside, leaving a gnawing pain in their place. There is a large fluctuating swelling in the popliteal space; no lateral movement.

August 31st.—Various splints and extension have been tried, with only temporary relief. To-day liquor epispasticus is to be employed to raise a blister, and then savine ointment is to be applied to the knee.

Sept. 16th.—MacIntyre's back splint applied.

24th.—Pain is getting worse, and the application of cocaine only stops the jumping very slightly. Indiarubber springs have been put under the bedposts to deaden the vibrations of the footsteps in the ward.

Oct. 7th.—After consultation with Mr. Willett, Mr. Baker, and the assistant surgeons, it was decided to examine the joint under an anæsthetic prior to amputation. This was done, but led to no new discovery. The man has most excruciating pain in the joint and cannot bear it being touched, however lightly.

13th.—An anæsthetic having been administered, Mr. Smith amputated the limb just above the knee-joint by anterior and posterior flaps. An incision was first made into the joint and a large quantity of bloody fluid escaped, but no pus. On examination after removal the following conditions were discovered:—The under surface of the patella is carious, and the cartilage on it is ulcerating and mostly gone. The condyles of the femur and head of the tibia are in a similar condition. The large cyst at the back of the joint, which contained a large quantity of bloody fluid, communicated with the bursa between the inner head of the gastrocnemius and semi-membranosus muscles, and so with the joint. The shrivelled-up sac of the old cyst was found running along the inner border of the gastrocnemius for about an inch and a half. It communicated by a very narrow passage with that at the back of the knee. The ligaments were all loosened, though not destroyed. Cartilages almost entirely destroyed; synovial membranes pulpy. No pus found in the joint.

Nov. 3rd. There has been no hæmorrhage, and the man is progressing fairly towards convalescence.

15th.—The temperature was quite normal up to the time of the operation; after the operation it was elevated for about four days. The wound is healing and the patient doing well, gaining flesh and strength. The operation has given very great relief.

GENERAL INFIRMARY, LEEDS.

TWO CASES OF RUPTURE OF THE BLADDER; REMARKS.

(Under the care of Mr. W. H. BROWN and Mr. M'GILL.)

FOR the notes of these cases we are indebted to Mr. H. Littlewood, resident surgical officer.

CASE 1.—James L——, aged twenty-six, by occupation a professional cricketer, was admitted on Oct. 18th, under the care of Mr. W. H. Brown, with the following history. For the past few weeks he had suffered from constipation, and had taken a good deal of aperient medicine. During the last week he has complained of having to pass his urine frequently and in small quantities, the urine dribbling away at times. He had a slight gonorrhœal discharge. On Oct. 15th he took a large dose of castor oil, and whilst making violent efforts at defecation he felt something give way on the right side of the body lower down—i.e., the right inguinal region,—and immediately felt a burning sensation all over the abdomen, which was succeeded by severe pain. Vomiting shortly afterwards commenced, and he had not passed flatus or fæces since the pain began. On Oct. 17th he was seen at 11 P.M. by Dr. Hogg, Mr. Hayman, and Mr. Brown. His condition was as follows. He was vomiting fæcal matter, was much collapsed, pupils widely dilated, pulse small and thready, surface cold and damp, abdomen greatly distended and tympanitic, and respiration rapid. The rectum on examination was found empty. Prostate large and tender; beyond the prostate a hard elastic swelling could be felt pressing upon the rectum. A No. 10 silver catheter was passed, four ounces of urine drawn off, and immediately afterwards about one ounce of coffee-coloured liquid containing some portions of what appeared to be breaking-down blood clot. A long tube was passed about eight inches up the bowel and ten ounces of warm water injected, with a negative result. The man's surroundings were so bad, and he himself so ill, that it was thought advisable to postpone any abdominal exploration pending his removal to the infirmary. Mr. Brown then punctured the abdomen with a No. 1 trocar with a view of relieving the difficulty of breathing. A puncture was made midway between the umbilicus and pubes, with the result that fluid, apparently urine, escaped and continued to drain for upwards of an hour, in all about two pints and a half. The catheter was again introduced, but only a teaspoonful of urine came through. Before admission to hospital, and after the trocar had been withdrawn, the patient passed urine voluntarily. He thinks he must have passed nearly a pint. Bowels not open, but he has passed flatus. No history of blow or other injury to abdomen can be obtained.

State on admission.—The patient is a strong, well-nourished man, of fairly regular habits; complains of some pain in the lower part of the abdomen; says he feels more comfortable than he did last night; appears collapsed; surface of body clammy. Temperature 98·4°; pulse 100. Abdomen somewhat distended, resonant all over.

Soon after admission he was seen by Mr. Brown and Mr. M'Gill. A catheter was passed and about eight ounces of urine drawn off, which was slightly tinged with blood. A feeling of fluctuation was obtained in the hypogastric region; a trocar was put in, but no fluid escaped. On examining the rectum, the prostate was found enlarged and tender. A sixth of a grain of morphia was ordered, and the abdomen poulticed. Patient vomited at 12 and again at 3 P.M.; vomit offensive and green. Complains of hiccough. At 6 P.M. the condition was more favourable. At 12 P.M. a sixth of a grain of morphia was given hypodermically; after this he slept off and on until 4 A.M. Vomited twice between this and 10 A.M., the vomit being of the same character as before.

Oct. 19th.—10 A.M.: After consultation it was decided to open the bladder by the median perineal incision. This was done by Mr. Brown, the patient being under ether. On exploring the bladder with the finger a slight roughening was felt, but no rupture made out. A large tube was then put into the bladder. The patient did not recover from the operation and died suddenly at 1 P.M.; troubled a good deal with hiccough before death. The temperature was never above normal.

The necropsy was made by Dr. T. Wardrop Griffith. Body singularly well nourished; abdomen rather fully distended. On opening the abdomen, a quantity of fluid, dirty orange-coloured and somewhat opaque, but not purulent, escaped. The folds of the small intestine protruded from the wound, and the further dissection showed that they were all greatly distended, and adherent to one another and to the under surface of the great omentum. The adhesions were quite recent, and the intestines could everywhere be separated from one another with perfect ease. Towards the pelvis the amount of fibrinous lymph was greater there, also the intestines were more matted, and their arrangement was such that fluid was incarcerated in small amount between the adjacent folds. Especially was this the case about the seat of the abdominal puncture, the mark of which was seen midway between the umbilicus and pubes. In order to midway between the umbilicus and pubes. In order to explore the pelvis the intestines had to be separated from the back of the bladder and from the sides of the pelvis. Here there was a large amount of lymph in soft masses, but no evidence in old adhesions of any antecedent inflammation. The posterior part of the bladder was coated with an extremely irregular covering of soft lymph, and about an inch below the reflection of the peritoneum from the upper part of the bladder, slightly to the right of the middle line, was an aperture that would admit one's forefinger with difficulty. The axis of this opening was vertical, and its margins were [redacted] of a small amount of

inflammatory lymph. The intestines were then examined, and found distended as far down as the splenic flexure. The sigmoid flexure contained more air than the descending colon, which differed from the rest of the intestine in not being injected. No mechanical block was made out. The pelvic organs were removed for further examination, and it was found that the interior of the urethra presented a perfectly normal appearance, there being no evidence of any catarrhal changes. The seminal orifices were slightly dilated. There was some matting of the tissues around the vesiculæ seminales and lower ends of vasa deferentia, so that much difficulty was experienced in dissecting the parts out. The matting was greater on the left than on the right side, and here the tissues formed a mass readily to be felt from the rectum. The tubercles of the vesiculæ were dilated, and contained some glairy fluid, which on microscopical examination was found to be pus, and did not contain spermatozoa. There was no pus in the matted tissues around the vesiculæ. The interior of the bladder was generally injected. At one point, one and a half inches below the rupture, was a roughened area, where the injection was most marked. Examination of the bladder at the point of rupture did not point to any ulceration or pre-existing disease. Other organs of body normal.

Remarks by Mr. BROWN.—That it is possible to have rupture of the bladder without injury, without stricture of the urethra, and without disease of the organ itself, is difficult to understand. The only case that I can find at all bearing upon the present one is recorded in THE LANCET of September 28th, 1873, by Dr. M'Ewen, and there the rupture was not suspected during life, as no opportunity occurred of observing the patient's symptoms, the man being moribund when taken to the hospital. Dr. M'Ewen refers to seven cases of "spontaneous rupture of the bladder" mentioned by M. Houël, and draws attention to the fact that in all these cases there existed "some mechanical impediments" to the outflow of urine, so that they can scarcely be said to come under the same classification as either Dr. M'Ewen's own case or the present one. The fact that the patient had the power of voluntary micturition up to the time of the perineal opening being made complicated the diagnosis, and indeed, so far as I can gather, this feature in the case is without parallel. Again, absence of any sign of disease within the bladder renders it a matter of difficulty to formulate a theory as to the cause of rupture which can be satisfactory. That the patient had had a gonorrhœa recently points to the possibility of the disease having been the starting-point of an inflammation which spread backwards, involving the structures round the neck of the bladder, thus causing retention of urine; and that the bladder giving way removed the pressure from the inflamed parts, and allowed of the passage of urine by the urethra once more, appears to me to be the most likely explanation of the course of events in this most unusual case.

CASE 2.—Martin B——, aged fifty-four, by occupation a publican, was admitted into the infirmary on Oct. 20th, under the care of Mr. M'Gill, in the evening, complaining of severe pain in the lower part of the abdomen and inability to pass urine. On Monday night, Oct. 18th, the patient was hurrying to catch a train and came violently into contact with an iron gate. The patient was knocked down and was carried insensible to a neighbouring house. Half an hour after the accident he regained consciousness and felt a "severe burning pain in the abdomen and bowels." The patient had been drinking a good deal in the afternoon. He remained in the house until the following morning, sleeping fairly well in spite of the pain, then returned home to Morley, taking a cab to the station and from the station at Morley home, and went to bed at once (midday). Dr. Clarke was sent for. Up to this date from the time of accident the patient had not passed urine. A hot bath was ordered; result *nil*. A catheter was then passed, and about a quarter of a pint of bloody urine drawn off. On Tuesday night and Wednesday morning the patient was again catheterised, when about the same amount of urine was drawn off, though there was rather less blood present. Bowels not moved since the accident, nor flatus passed.

State on admission.—The patient is a healthy-looking, well-nourished man, a little collapsed; has not passed urine since it was drawn off this morning; complains of pain in lower part of abdomen. Abdomen somewhat distended; resonant all over. No signs of fluid could be detected. Bowels not open, nor flatus passed. Temperature 100·4°; pulse 100. At 11.30 P.M. a soft catheter was passed and five ounces of blood-stain[illegible]

Oct. 21st.—The patient has suffered considerable pain the greater part of the night, and has slept a little at times. Temperature 98·4°. Mr. M'Gill passed a soft catheter and drew off thirty-three ounces of urine mixed with blood. At a consultation ruptured bladder was diagnosed, and abdominal section advised. At 3.30 P.M., the patient being under the influence of ether, Mr. M'Gill made an incision in the middle line, about four inches long, extending down to the symphisis pubis. All bleeding having been stopped, the peritoneum was opened; some urine escaped. The hand was then introduced, and a rupture in the bladder was found about four inches long, extending from about half an inch in front of the peritoneal reflection from the apex of the bladder down to the fundus, where the peritoneum is reflected on to the rectum. The abdominal incision was now enlarged for about two inches upwards. An air tampon was introduced into the rectum and distended, which brought the rent in the bladder into easy position for suturing. Nine chromic gut sutures were now introduced, care being taken not to include the mucous membrane of the bladder. The bladder was then filled with a weak solution of boracic acid, to ascertain if the wound leaked, and it was found to do so in two places. Two other catgut sutures were then introduced, and the bladder again injected. No leakage occurred. The tampon was then removed from the rectum. The peritoneal cavity contained about a pint of urine. (No peritonitis.) This was now thoroughly washed out with about two gallons of a 5 per cent. warm solution of boracic acid. The lower part of the incision into the peritoneum—i.e., the reflection from the apex of the bladder—was sutured by two catgut sutures. An incision about three quarters of an inch long was now made into the bladder (for the purposes of drainage) in front of the peritoneal reflection from the apex of the bladder, and a large drainage-tube was introduced and brought out at the lower part of the wound. The abdominal wound was now closed with wire sutures, transfixing the whole thickness of the abdominal wall, and bringing the two peritoneal surfaces in contact. The wound was dressed with iodoform and salicylic silk, except at the lower part, where a drainage-tube protruded. The tube was surrounded by a piece of jaconet (so as to prevent urine soaking the dressing), and a large pad of cotton-wool over this. The operation lasted one hour and four minutes. The spray and other antiseptic precautions were used. At 10 P.M. the patient seemed fairly comfortable; temperature 98°; pulse 130, small. A nutrient enema was given, consisting of two ounces of beef-tea, one ounce of brandy, and an egg.

22nd.—12.30 A.M.: Temperature 99·2°. Patient, feeling sick, asked for some milk and soda-water. After having it he vomited, and continued to do so at intervals till 1.30. Slept until 2 o'clock. Began to vomit again at 3.30. The vomit, which had been before of a dark-brown colour, was now almost black. Complains of burning pain at the bottom of the abdomen. 4 A.M.: Another enema given. 6 A.M.: Patient much weaker; pulse feeble, rapidity increased. Another enema given, but not retained. From this time the patient got gradually weaker, the pulse becoming almost imperceptible, and he died at 9 A.M. Some urine was secreted and soaked into the cotton-wool over the drainage-tube. This was changed two or three times.

A necropsy was made by Dr. Churton twenty-seven hours after death. The rent in the bladder, stitched up as described above, was seen; it was very nearly in the middle line. No fluid in the peritoneum; no signs of peritonitis. Lungs congested and œdematous. Nothing very abnormal was noted in the other organs.

Remarks by Mr. LITTLEWOOD.—The chief points to note in the case are in the treatment: 1. The introduction of the air tampon into the rectum; this greatly facilitated the suturing of the wound in the bladder. 2. The attempt to drain the bladder above the pubes by inserting a tube into an incision made in the vesical wall in front of the superior false ligament. Up to the time of death the urine was prevented from soaking into the dressing covering the upper part of the wound by means of the jaconet surrounding the tube, and by changing the cotton-wool, into which the urine soaked every hour. Mr. M'Gill's reasons for draining above the pubes were—(*a*) The experience of a case of ruptured urethra in which incisions had been made, both in the perineum and above the pubes; it was found that nearly all the urine came out through the supra-pubic wound. (*b*) To avoid making a second incision in the perineum.

PATHOLOGICAL SOCIETY OF LONDON.

Vegetable Tumours in relation to Bud Formation.—Cerebro-spinal Meningitis leading to Œsophageal Abscess.—Congenital Contraction of Stomach.—Aneurysm of Undefended Space.—Cystic Tumour of Cæcum.—Carcinoma of Vesicula Seminalis.—Imperforate Anus.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. Syer Bristowe, F.R.S., President, in the chair.

Mr. ROGER WILLIAMS read a paper on Vegetable Tumours in relation to Bud Formation. He treated the subject from the evolutional standpoint. In its simplest form bud formation is nothing but cell multiplication by fission or gemmation. In the Thallophyta buds are represented by simple proliferous outgrowth of the fronds. The simplest buds consist either of single lowly-organised protoplasmic cells, or of groups of such cells derived from simple cells. In the higher plants under ordinary circumstances a bud develops into a branch, but disturbances in nutrition may give rise to other formations—spines, tendrils, &c. Adventitious buds have been found on almost every part of plants; they may arise wherever undifferentiated cells are present. These anomalies in the higher plants may be ascribed to reversion to an original mode of growth. Darwin had described "sports" as bud variation. Vegetable tumours were described as essentially abnormal bud evolution from altered nutrition. These tumours of trees were divided into three classes:—1. Discontinuous or circumscribed, including the nodules on the bark of the beech, elm, oak, &c. They first appeared as globular bodies in the cellular tissue of the bark. 2. The continuous tumours or exostoses. 3. A group including those excrescences which present a surface thickly studded with shoots and stunted branches. Excess of nutriment was the chief etiological factor.—Mr. SHATTOCK thought that the subject was thoroughly threshed out. The chief interest was that the origin of the growths bore out Cohnheim's view of the origin of tumours in remnants of undifferentiated embryonic tissue.—Mr. STEPHEN PAGET referred to a paper by Mr. Jacobson in the Guy's Hospital Reports, in which tumours of the parotid region were shown clearly to favour Cohnheim's theory.

Dr. HALE WHITE showed a specimen of Œsophageal Abscess in a case of cerebro-spinal meningitis, from a girl who was in Guy's Hospital for a month with retracted head, arching of the spine, cephalic and spinal pain, and other symptoms of cerebro-spinal meningitis. About eighteen hours before death pus began to pour from the mouth, but no cause for this could be discovered. The pus trickled down into the lungs and the patient died. At the post-mortem examination it was found that the spinal and cranial bones, dura mater, and cerebral vessels were normal without any trace of tubercle; at the base of the brain and the posterior surface of the spinal cord there was abundant purulent meningitis. Opposite the cricoid cartilage, on its posterior surface, there was an oval ulcer, with its long vertical diameter measuring an inch and a quarter. At its bottom the cricoid cartilage was exposed, but not necrosed; opposite this ulcer was another, on the posterior wall of the pharynx. There was some bronchitis, and the mitral valve was thick. The rest of the body was healthy. The ulcers above described were probably due to an abscess, which had existed at the upper part of the œsophagus at its junction with the pharynx; this bursting had caused the discharge of pus noticed during life. It appeared that the cause of the abscess was the extreme retraction of the head, throwing the larynx backwards and the spine forwards, so that the friction of the cricoid against the spine during respiration set up the abscess. He thought that the case was of interest, as also possibly an example of a rheumatic meningitis, for the patient had had rheumatic fever twice, and there was no cause obvious on the post-mortem examination for the inflammation of the meninges. In reply to Dr. Bristowe, the author said that there was but a slight amount of pus.—Dr. BRISTOWE referred to a case of suppurative meningitis throughout the brain and cord, in which the pus escaped through all the inter-vertebral foramina; it would be conceivable that a retro-œsophageal abscess might be formed by an accumulation or extension of pus from inter-vertebral notches.—Dr. WHITE said the case was carefully examined, and nothing of that kind was found.

Mr. LEOPOLD HUDSON read a case of Hour-glass Constriction of the Stomach, taken from a single woman fifty-nine years of age, admitted into the Temperance Hospital under Mr. Pearce Gould with scirrhus of the breast. The stomach presented in its centre a constriction large enough to admit the thumb. On the smaller curvature proximal to the stricture was a small cicatrix, and distal to it was a callous ulcer. The cardiac sac was dilated. Twenty cases of hour-glass constriction were referred to; in nine of which the mucous membrane showed no sign of present or previous ulceration. The author regards the condition as congenital, and due to arrest of development at a site where temporary physiological constriction is common, the ulceration being secondary and caused by the irritation of the gastric contents when churned about by disordered peristalsis.—Dr. NORMAN MOORE thought it was possible that the specimen was a sort of reversion to that condition of stomach seen in several mammals. The œsophagus appeared to be perfectly normal, which rather went against this view.—Mr. W. R. WILLIAMS could not accept the view that the specimen had any resemblance to the ruminant stomach, nor did he accept Mr. Hudson's suggestion of the origin of the constriction.—Mr. F. S. EVE did not agree that the constriction was to be explained on the theory of evolution. He had dissected a fœtus in which constrictions existed in many parts of the intestines.—Mr. HUDSON, in reply, said that he did not believe that an intra-uterine band of lymph had caused the constriction, but he imagined that there was an arrest of development at the site of constriction, for the calibre at the obstruction was about the size of that of the primitive stomach.

Mr. D'ARCY POWER showed two specimens of Imperforate Anus. In one case the rectum opened into the prostatic part of the male urethra by a small aperture. The specimen came from the body of a child aged twenty-three days; lumbar colotomy had been performed three weeks before death. In the other it opened into the vagina of a newly-born child.—Mr. B. SUTTON asked if there were any evidence of the existence of a post-anal gut.—Mr. S. PAGET referred to cases by M. Bouchut and Mr. Horsley. In the case of the latter observer, there was a minute canal leading from the situation of the anus upwards in the direction of the intestinal sac.—In reply, Mr. POWER said there were no diverticula and no evidence of a post-anal gut.

Dr. HARRINGTON SAINSBURY showed a Cystic Tumour of the Cæcum from a subject dead of typhoid fever. It contained a thick viscid mucoid fluid. Externally it was covered with mucous membrane. Internally it was lined by a serous layer. It occupied and distended the first portion of the ascending colon, and appeared to spring from the anterior wall of the colon just at the level of the upper lip of the ileo-colic valve. The mucous lining of the cyst corresponded in microscopical structure to the mucous coat of the large intestine. Mr. Sutton's suggestion was adopted that the tumour was due to cystic dilatation of one of the lips of the ileo-colic valve. It was not an entero-cystoma.

Mr. E. HURRY FENWICK showed a case of Carcinoma of the left Vesicula Seminalis, which originated probably in the posterior part of the left lobe of the prostate and had involved the bladder and vesicula secondarily. The clinical history lasted nine months; there was great frequency, with finally incontinence, of the urine, and frequent and profuse attacks of vesical hæmorrhage. There was no evidence of the growth in the urine. There were no secondary deposits.

Dr. NORMAN MOORE showed an Aneurysm of the Undefended Space. The aneurysm projected as a three-lobed tumour into the right auricle just above the attachment of the tricuspid valve. The external opening was into the sinus of Valsalva, and not into the heart. It was taken from a man who died at the age of twenty-one years after six attacks of rheumatic fever. There was well-marked stenosis of the mitral valve, some stenosis of the tricuspid valve, and the aortic valves were partly destroyed and fringed with numerous growths. The aneurysm was clearly an acute one, since signs of endocarditis were present. The aneurysm was partly filled with fibrin, and had a roughened sac.—Dr. S. COUPLAND thought the aneurysm was rather of aortic than cardiac description.—Dr. ANGEL MONEY referred to a specimen of aneurysm of this space in the Museum of the Hospital for Sick Children: the walls of the aneurysm were formed of the opened-up layers of the septal cusp of the tricuspid valve.

The following card specimens were shown:—Dr. Henry Maudsley: Embolism of Basilar Artery, with rupture of left posterior cerebral artery and copious extravasation of blood under the base of the brain, and extended on to the vertex. Mr. S. G. Shattock: Chondrifying Sarcoma of Male Bladder, papillomatous on the surface.—Mr. T. D. Savill showed a specimen of Unilateral Meningeal (Arachnoid) Hæmorrhage removed from a woman aged sixty-nine, in whom the symptoms during life were those of delirium and coma.

CLINICAL SOCIETY OF LONDON.

Extirpation of the Larynx for Epithelioma.

AN ordinary meeting of this Society was held on the 12th inst., Mr. Thomas Bryant, F.R.C.S., President, in the chair. Three important contributions to the surgery of the larynx occupied the whole of the evening. The attendance of members was very numerous, every available seat being occupied.

Mr. HENRY MORRIS read a case of Excision of the Whole Larynx for Epithelioma. The disease was confined within the larnyx. For over three years the man, aged fifty-nine, had suffered from increasing laryngeal obstruction, and tracheotomy had become necessary five months before the laryngectomy. From the downward extension of the disease, the tracheotomy tube became depressed, and was itself a source of never-ceasing irritation, though necessary for respiration. Under these extreme conditions the larynx was excised with the cricoid cartilage. Death followed the operation on the eighth day from exhaustion. At the post-mortem examination, the whole of the disease was found to have been removed, and there were no secondary deposits in any part. Mr. Morris thought that the total extirpation of the larynx ought to be done very seldom; and not until all less severe measures had been tried and failed. There were, however, two conditions which indicated and justified the operation: first, where the disease was entirely intra-laryngeal, and could therefore be completely removed; or, secondly, where, after tracheotomy, the sufferings of the patient were persistent, and suffocative cough and dyspnœa proved unrelievable by other means. Both these conditions existed in the above case, and though death was the final result the relief of urgent symptoms which was afforded by the operation was great and substantial.

Dr. FELIX SEMON read a paper on a case of Partial Extirpation of the Larynx for Epithelioma of the Left Ventricle of Morgagni. The patient was a barrister, aged fifty-two, whose only complaint was loss of voice, which had gradually developed within the course of a year from an originally slight hoarseness. On laryngoscopic examination nearly the whole of the left vocal cord appeared to be embedded in an irregularly longitudinal greyish-white warty tumour, of about the size and form of a small bean. Microscopic examination of a small fragment of the tumour, removed by intra-laryngeal operation, showed it to be a cornifying epithelioma. Extirpation of the left half of the larynx, with the exception of the cricoid cartilage, was successfully performed by Dr. Eugen Hahn. The tumour was found to spring with a broad pedicle from the left ventricle of Morgagni. The patient made a good recovery, which was only retarded by an extensive bronchial catarrh and slight pleuritic symptoms. These were probably due to the escape of some blood into the lower air-passages during the operation. At present—i.e., five months after the operation—the patient is quite well, swallows with ease, does not wear a tracheal cannula, is free from any trace of recurrence, and his voice has so surprisingly recovered, though he possesses but one vocal cord, that he wishes to resume his practice at the bar. Dr. Semon dwelt especially on the necessity of a thorough occlusion of the lower air-passages before the latter stages of the operation were proceeded with, and corrected a misapprehension of some observations he had made in the discussion on extirpation of the larynx during the seventh international Congress. He was, he said, by no means an opponent *a principio* to extirpation of the larynx in really suitable cases of laryngeal carcinoma, but he opposed the formulation of the indication that "extirpation of the larynx was required as soon as the diagnosis was clearly made," because in a large proportion of cases the diagnosis could only be established with certainty at a time when, in his opinion, the operation no longer offered any reasonable chances of success. This question was discussed at some length, and Dr. Semon finished by saying that he entirely agreed with Mr. Butlin's dictum, that in the immediate future extirpation of the larynx for carcinoma should be practised only for intrinsic carcinoma, which was still limited to the interior of the larynx. Hence *early* diagnosis, if possible, by means of intra-laryngeal removal and microscopic examination of a small fragment of the new growth was of the highest importance.

Mr. BUTLIN read a paper on a case of Epithelioma of the Vocal Cord, for which partial excision of the larynx was performed. The patient was a gentleman aged fifty, who suffered from hoarseness of two years' duration. He had a warty growth on the left vocal cord, which appeared to be non-malignant, although it presented some suspicious characters. At different times, during a period of six months, portions of the growth were removed with forceps. Recurrence took place, and the cord exhibited impaired mobility. After a consultation with Dr. F. Semon, it was decided to excise a portion of the larynx. The operation was performed by Mr. Butlin on June 26th. The left half of the larynx was removed, together with the true and false cords of the right side, for the disease had extended on the true cord and along its under aspect, so that it could not be perceived with the laryngoscope. Hahn's tracheotomy tube was used during the operation, and was left in for two days. At the end of two days it was replaced by a smaller tube. During the first few days after the operation the patient was fed through a tube by means of a syringe. The temperature never rose over 100°, and the pulse was, almost from the first, from 80 to 84. On the fifth day the patient began to swallow. On the seventh day the tracheotomy tube was permanently removed. Three weeks after the operation he drove to Wimbledon, and after spending a week there he returned to his home in the country. The chief, and indeed only, trouble from which he suffered was cough, which commenced as soon as the large tube was replaced by a smaller tube, but which gradually became less distressing, and finally ceased within a few days after the permanent removal of the tube. He was last seen by Mr. Butlin on September 28th, when the wound was healed, with the exception of a little sinus at the lower part. There was no sign of recurrent disease or of affection of the glands of the neck. His general health was excellent, and he was able to speak in a gruff whisper, very loud and distinct. The points to which the author drew attention were: the rarity of the operation in England; also, the reasons which had led him to perform the operation—namely, the intrinsic origin and limited extent of the growth, the absence of lymphatic affection, the good health of the patient, and the belief that the excision might be limited to half the larynx. Particular attention was directed to the fact that the soft parts were raised off the cartilage on the right side without removing the framework of the larynx. The cough which troubled the patient was attributed to the fact that the second tube was too small, and it was suggested that a larger tube would prevent the occurrence of such a cough in other cases. The manner of feeding the patient during the first few days was alluded to. And, lastly, the power of producing a hoarse whisper after removal of the true and false cords from both sides was mentioned.

The PRESIDENT remarked on the importance and interest of the papers, which dealt with a subject which would doubtless have startled the founders of the Clinical Society. —Mr. LENNOX BROWNE asked Mr. Morris at what part of the trachea tracheotomy was done. In his opinion the tracheotomy ought to be performed low down at the date of the operation for extirpation of the larynx, a few minutes merely intervening between the two operations. The value of careful and repeated microscopical examination of the growth was commented upon. It was possible that the nature of the cases changed after repeated intra-laryngeal irritation by operations for the removal of small portions. Mr. Butlin's case seemed to point in this direction. Sufficient time had not yet elapsed to say for certain that the cures were permanent in Dr. Semon's and Mr. Butlin's cases. —Mr. E. H. FENWICK had seen two cases of total extirpation of the larynx in the practice of Thiersch of Vienna. In one the man was able to make musical sounds by the aid of an artificial larynx.—Mr. T. PICKERING PICK had once performed the operation of total extirpation of the larynx. But he hoped never to be called upon to perform the operation again. It left an enormous chasm, and was a

horrible sight. It was most important to select cases for operation. His own experience did not lend support to the value of conservative practice in the treatment of epithelioma of the larynx, as recommended by Mr. Butlin. In June, 1885, after a preliminary tracheotomy, he (Mr. Pick) scraped away the soft parts, including the whole of the epithelioma, from the larynx, but within three months the neoplasm returned and the case terminated fatally. The method of feeding was of paramount importance; he advocated the use of a soft gum catheter passed through the nostril into the gullet and left there for many days, as was done with great success in a case of cut throat in St. George's Hospital.—Mr. H. MORRIS, in reply to Mr. L. Browne, said that the first and second rings of the trachea had been divided; the high tracheotomy had advantages. As to the feeding of the patient, he had tried several soft tubes, but specially those known as Durham's tubes; but the patient had the greatest aversion to the use of any. Before the operation he had thought to put his trust in rectal alimentation. In this particular case he had not performed the operation for the cure of the disease, but it was because the patient urgently demanded relief from dyspnœa and its attendant distress. However, such a case might have ended differently had the patient been less exhausted. It was only by publishing failures as well as successes that any just estimate of the operation as a means of cure could be formed. The necropsy showed that there was no glandular enlargement and no secondary deposits, and that the whole of the disease had been clearly removed.—Dr. F. SEMON said that in his experience it was the usual thing for the patient to decline operation, for he always laid before them full particulars as to the risks to be run. He need hardly say that his publishing the case was not with a view to manufacture favourable statistics, but rather to show that the surgeon should carefully select cases for operation.—Mr. BUTLIN repudiated Mr. L. Browne's suggestion, and said that from the first he was of opinion that the tumour was not benign. His advocacy of conservative surgery for the larynx did not mean that a scraping operation should be done; but the scissors and knife should be used as in epithelioma of the lip, and the growth widely excised. Mr. Butlin's own opinion was strongly against the performance of total extirpation, and he considered there was no defence to this kind of surgery. There was but one case, of Hahn's, that lived four years after the operation, and only six or seven in which the patients were alive more than a year after it. Only thirty out of sixty-five cases of complete extirpation recovered from the operation, for thirty-five died of the operation itself. If a patient consulted a surgeon for epithelioma of the larynx, and there was nothing for it but excision of this organ, he would be bound to inform the patient, in answer to questions, (1) that it was a dangerous operation, the mortality of which was 40 to 45 per cent.; (2) that he would in all probability not be cured of the disease, for recurrence would probably take place in a comparatively short time; and (3) that he would not even experience much relief from distressing symptoms, for the difficulty in swallowing and breathing would be fully as great after as it was before the operation.

The following living specimens were shown:—Mr. R. W. Parker: (1) Congenital Double Talipes Calcaneo-valgus and Genu Recurvatum; (2) Girl, aged thirteen, from whom the Patella was removed for Primary Sarcoma of that bone; (3) A girl showing the result of an Arthrectomy for Tubercular Disease of Synovial Membrane. Mr. Pearce Gould: Congenital Fusion of Fourth and Fifth Metacarpal Bones, and Deficiency of Right Fibula. Sir Henry Thompson: A man from whom a Vesical Tumour had been removed. Mr. G. H. Makins: A case of Traumatic Cephal-hydrocele. Dr. Percy Kidd: Tubercular Tumour of Larynx. Dr. Samuel West: Epithelioma of Larynx.

MEDICAL SOCIETY OF LONDON.

A Rare Case of Epilepsy.—Epileptic Guinea-pigs.

An ordinary meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, President, in the chair.

Dr. HUGHLINGS JACKSON related the case of a boy, seven years of age, in whom Epileptic Fits were artificially induced by any unexpected touch on the head. When three days old the boy had a convulsion. At the age of two years and a half he had an "ordinary" epileptic fit. Of these latter fits he had had four attacks of the same kind, or rather *degree*. Ever since the first so-called ordinary epileptic fit some imperfect use of the left arm and leg was noticed, and has ever since remained. About the age of two years and a half the boy began to fall down, but these falls were really fits. He never "fell" unless the head or face were touched, but the fit would not occur if he knew he was going to be touched. Stoppage of respiration was very evident in the fit. The eyes were turned to one side, generally the right. Sometimes as many as fifty falls occurred in one day, and never a day passed without some. Touching any part of the head or face was effective. Several appeared also during sleep when he accidentally touched his face or head. These sudden inopportune falls had caused enlargement of the left frontal eminence, and also that of the right side. The left arm was slightly less in circumference, and its movements were clumsy; there was something like athetosis in the left hand when the right hand was engaged in drawing or writing. He limped with the left leg, which was also less in circumference than the right. There was no alteration in the knee-jerks, and no ankle clonus. Perhaps the left side of the head was more sensitive, but no one place could be made out to be more sensitive than another. At times the boy said his left arm felt "heavy." The fits were not opisthotonic, as happened in feigned fits. Dr. Jackson described three forms of epilepsy—(1) epilepsy proper; (2) epileptiform seizures; (3) due to nervous discharges in the pons Varolii or medulla oblongata. In the case above there was a local lesion somewhere, as the hemiplegia showed. The epileptogenous zone was less defined than occurred in Brown-Séquard's guinea-pigs. Nervous discharge in some part of the pons was the probable cause of the falls or fits.

Mr. VICTOR HORSLEY showed photographs, projected on the screen with lime-light, of Guinea-pigs suffering from artificially induced Epilepsy. The fit was essentially momentary in character, lasting but a few seconds, and so the photographs had to be of the instantaneous order. Hemisection of the spinal cord and exposing the sciatic nerve, nipping it, and closing the wound, were the artificial methods of induction employed. If the skin of the angle of the jaw or that behind the angle of the eye were touched, there was a momentary interval in which the animal seemed dazed or squeaked. This period was followed by a period of tonic spasm, beginning in the head and neck, which were turned towards the side on which the cord was divided. Complete pleurosthotonos followed. Then consciousness was lost, the animal fell on its back, and the limbs were agitated by rapid clonic spasm. If the sympathetic nerve on one side of the neck was divided no change was noticed in the fits, and if the vessels of the exposed cerebral cortex were watched no change was observed in them; so the fits were probably not due to the sympathetic nervous system. Again, vaso-motor conditions take an appreciable time to develop. So Mr. Horsley considered that the fits were due to a neurosis, which began first in the right side of the brain, explaining the left pleurosthotonos, and then passed over to the left side of the brain. — Dr. HADDEN related a case of epilepsy which was attributed to lesion of the sciatic nerve due to an injury. The fit began with pain in the cicatrix, which passed up to the head and then consciousness was lost. The pupil did not react to light, nor was the tongue bitten except once. Stretching the sciatic by forcible flexion of the thigh was accompanied by a fit; but the nerve was stretched, peripherally and centrally, after incision over it, and the fits ceased for eleven days and were not frequent afterwards, and later still had entirely disappeared.—Dr. HUGHES BENNETT related a case of severe and frequent epilepsy that began with a visual aura and maniacal attacks. There was an injury and scar which topographically corresponded to the angular gyrus. And sometimes spontaneously, and sometimes artificially, by pressing on the scar the fits came on. About four months ago Mr. Gould cut down on the angular gyrus, and probed it without detecting organic disease. There had been, however, no fits since the operation. In another case a woman had a peculiar sensation running up the arm, and here also Dr. Bennett could artificially induce attacks.—Dr. EWART related a case of fits having the same characters as those related by Dr. Jackson, though not artificially induced, occurring in a little girl in whom the presence of hemiplegia pointed to a lesion of the brain.—Mr. R. W. [illegible] of epilepsy induced

by probing a diseased portion of the femur. Amputation of the limb was followed by complete recovery.—Dr. BERVOR asked how it was that consciousness was lost if the nerve discharge occurred in the pons Varolii.—Dr. HUGHLINGS JACKSON, in reply, was of opinion that the pons was the seat of the discharge because the guinea-pig had fits after removal of the hemispheres, and also because rabbits could have fits after similar removal, on being bled to death, as Kussmaul and Tenner had shown. There was thus sufficient evidence to prove that the grey matter of the pons contained enough energy to produce a fit as the result of the rapid discharge of its energy.—Mr. VICTOR HORSLEY, in reply, thought that the sequence of latent period, tonic spasm, clonic spasm could rarely occur except when the cerebral cortex was the seat of the nerve discharge. Brown-Séquard had shown twenty years ago that stretching the sciatic nerve stopped the fits.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on the 3rd inst., Dr. J. B. Potter, President, in the chair.

The following specimens were shown: Dr. Horrocks: A section from Cancer of Cervix Uteri, showing epithelioma passing into medullary carcinoma. Dr. Gervis exhibited some drawings from microscopical sections of the surface of a Fibroid Polypus, which showed that the epithelium is ciliated in positions where there is neither friction nor pressure.

Papilloma of the Fallopian Tube and the relation of Hydro-peritoneum to Tubal Disease, by Mr. ALBAN DORAN.—The discussion on this paper, read on Oct. 6th, was opened by Dr. ROUTH, who said that in a former paper Mr. Doran showed how disease of the Fallopian tube could be produced by extension of inflammation from the vagina (as in gonorrhœa), leading to endometritis, pyo-salpingitis, peritonitis, and death. He now had shown that the Fallopian tubes were liable to be affected with papillomata, and became a very painful disease. Dr. Routh thought that a similar propagation upwards could produce these papillomata, as the vulva, vagina, and neck of the uterus were liable to be studded with warts and cauliflower excrescences, and polypi were found in the uterus, all of which, when examined microscopically, were similar. Now from what source did these warts originally arise? In large quantity they existed either in married women or women who had had sexual intercourse. They were eminently contagious, and might possibly be caught as ordinary warts were. The contact of a warty secretion could produce a wart. Possibly they were sometimes sequelæ of venereal disease, like condylomata &c., and means which were found to cure syphilis often cured these warts completely. It would seem that according to the seat of these papillomata the secretion from them varied. In the vagina they gave rise to a very fetid secretion; in the uterus, to a sanguineous one; in the tubes, to a very acrid or but slightly irritating secretion. Fortunately, in the former case the violent inflammation produced closed the fimbriated extremity, and so prevented extension of the inflammation to the peritoneum. In the latter case the secretion resembled a mild catarrhal fluid; the irritation was insufficient to cause closure of the tube, and hydro-peritoneum, or more properly sero-peritoneum, resulted. It seemed highly probable that papillomata of the fimbriæ might give rise to papillomata of the peritoneum and ovaries. It has been affirmed that after operation papillomata of the peritoneum sometimes disappeared, while at other times they assumed a malignant type. Surely the explanation was that in the former examples there was no cancerous diathesis, while in the latter there was; and exactly as a blow or irritation may cause cancer in a person with cancerous diathesis, so benignant papillomata may become malignant. The conclusion to be drawn from these general principles was to enforce the treatment of these cases early, and so to prevent the extension of serious disease.—Dr. HORROCKS said that, *à priori*, disease of the Fallopian tubes should be rare, since they had such an easy function to perform. In a careful investigation made at his request in the post-mortem room at Guy's Hospital by Drs. Goodhart, Mahomed, and Carrington during the last three years, there was not one instance of papilloma of the Fallopian tube, and, considering the large number of post-mortem examinations, this affection must be looked upon as very rare; when it did occur it would be difficult to diagnose.—Dr. GERVIS gave some particulars of a case of pelvic papillomata he had recently operated on. The growths covered the tubes and ovaries on both sides, and were scattered about the peritoneal surfaces. The patient had been tapped for ascites six weeks before Dr. Gervis saw her. He removed a moderate-sized cyst and as much of the papillomatous outgrowths as was practicable. The patient made a good recovery, and now, between three and four months from the operation, there has been no recurrence of the hydro-peritoneum.—Dr. CHAMPNEYS had recently admitted a case into St. George's Hospital in which abdominal section had been done four years ago, and the peritoneum and liver had been found covered with papillomata springing apparently from the region of the tube or ovary. Till two months ago no symptoms had occurred, and then a soft swelling appeared in the line of incision. A little pus and serum was discharged, but no recurrence of the disease was found.—Mr. BLAND SUTTON observed that he had made a careful study of Fallopian tubes removed for various diseases, and had found that in cases of ovaritis due to extension of gonorrhœa a papillomatous condition of the mucous membrane was not infrequent, and he had found it possible to trace every gradation from simple or slightly branched villi to dendritic masses with narrow pedunclés completely occluding the tube.—Mr. ALBAN DORAN, in reply, said that Dr. Routh's remarks could not be directly applied to the two cases upon which the paper was based. There was no probability of venereal taint—at least in the first case. With regard to hydro-peritoneum, he had explained how most diseases of the tube sealed up the ostium and saved the peritoneum from irritation; still, a mild catarrh of the tube, such as might be due to gleet, might fail to cause the ostium to be closed, and thus some discharge would escape into the peritoneal cavity and cause hydro-peritoneum.

On the Obstetrics of the Rhyphotic Pelvis (second communication), by Dr. CHAMPNEYS.—The author referred to his first paper on this subject in vol. xxv. (for 1883) of the Society's Transactions, in which he arrived at the following conclusions:—*(a)* The head is usually more or less transverse at the beginning of labour, and not antero-posterior, as usually described. *(b)* During labour the occiput rarely turns forward, deep transverse position is common, and posterior rotation not uncommon. *(c)* The head sometimes (probably not commonly) passes out of the pelvis practically between the tubera ischii in front and the sacrum and coccyx behind, entirely neglecting the anterior part of the pelvis. These conclusions were directly contradictory of the received accounts. The author referred to the criticisms on his description of the mechanism, and sought to show that they were not founded on fact, and were self-contradictory. He then recorded an additional case carefully observed by himself, including the mechanism of labour, and the moulding of the fœtal head and its dimensions. He analysed two other cases recorded since his paper, making a total of thirty-five labours in twenty-two women. These cases entirely confirm the opinions expressed in the former paper. The cases on which the usual statements were based cannot be found if they ever existed.

A Case of Lupus, Stricture, and Atresia of the Female Urethra, by Dr. HERMAN.—The patient, aged forty-eight, had had one child. She had suffered from trouble in micturition and occasional attacks of retention of urine for twelve years. She had at one time had an abscess in the groin, and had some operation done which she described as the removal of a growth from the urinary passage. She came to the London Hospital suffering from retention of urine; no catheter could be passed, but a warm bath gave relief. Three days afterwards the retention recurred; not only was the bladder full, but the urethra was distended into a sausage-like swelling. The meatus was blocked with fibrous outgrowths, between which no channel whatever could be found, not even for a fine probe. There was hypertrophy of one labium minus and perforation of the other, but no visible ulceration; and Dr. Herman concluded that the complete occlusion probably resulted from adhesion of ulcerated surfaces closing the narrow tortuous channel between the outgrowths which blocked the meatus. The channel was reopened with a trocar, and kept patent by the passage of bougies. The patient had since remained free from all trouble for three years. The author remarked on the sausage-like dilatation of the urethra, which showed that

the retention was due simply to blocking of the meatus, and not to swelling or spasm of the canal. He remarked on the rarity of stricture from fibrous outgrowths at the meatus, and quoted two cases, the only ones he had been able to find.

MANCHESTER PATHOLOGICAL SOCIETY.

THE annual meeting of this Society was held on Oct. 13th, J. Dreschfeld, M.D., President, in the chair. The reports of the treasurer and secretary were presented, and office-bearers for the ensuing year were elected.

Rhino-scleroma.—Dr. DRESCHFELD exhibited a section of tissue from Rhino-scleroma, and gave a brief sketch of the more recent researches on this subject. The section (for which he was indebted to Dr. Payne of London) showed the presence of numerous bacilli occurring in small masses in the midst of the tissue. These bacilli were smaller than the tubercle bacilli, less slender, and the extremities slightly thickened. These micro-organisms were unlike those shown recently at the Berlin Medical Congress by Paltauf, who describes the organism as similar, if not identical with, Friedländer's pneumonococcus, and who obtained pure cultivations which, as regards their form of cultivation, their microscopic appearance, and their behaviour when injected into mice, resembled the pneumonococcus.

Mycosis Fungoides.—Dr. DRESCHFELD also showed a section of Granuloma Fungoides prepared from a small Tumour, removed during life by Dr. Payne. Numerous sections had been made and stained after Gram's method, but neither in the bloodvessels nor in the tissues were any organisms seen. Dr. Dreschfeld remarked that Köbner's investigations have given equally negative results, and though the disease most probably is parasitic, it seems very doubtful whether the micrococci seen by Rindfleisch, Hochsinger, and Schiff are the pathogenic organisms of this disease.

Multiple Papilloma of the Larynx.—Dr. HODGKINSON showed several small Papillomatous Growths from the Larynx, coughed up at short intervals by a woman aged forty. When first seen, fourteen months ago, she was suffering from complete aphonia and dyspnœa. Laryngoscopic examination revealed the presence of three growths. Marked improvement resulted from repeated applications of the galvano-cautery, and the patient ceased to attend. After an absence of four months she was admitted into the Throat Hospital at Bowdon with such urgent symptoms that tracheotomy was performed by Mr. Hardie. Dr. Hodgkinson called attention to a point of great interest—viz., the steady diminution in the size of the growths under the influence of the physiological rest since the operation. Microscopically, the growths were of a simple character.

Cerebral Tumour.—Dr. ASHBY exhibited the brain of a boy of five years, who had suffered for three months before his death with paresis of his left arm and leg, and well-marked choreic movements of the arm. The contractions of the muscles of the forearm were rapid and irregular, closely resembling those seen in a severe case of chorea. The arm was mostly adducted, and held somewhat behind his back, the forearm pronated, and the fingers working vigorously. He died of tubercular meningitis. At the post-mortem a cheesy tumour about one inch in diameter was found in the right optic thalamus, compressing the internal capsule.

MIDLAND MEDICAL SOCIETY.

A MEETING was held on Oct. 20th, Mr. Lloyd Owen, F.R.C.S.I., President, in the chair.

Sarcoma of Tibia.—Mr. CHAVASSE showed a specimen of a mixed form of Central Sarcoma, originating in the Shaft of the Tibia of a Miner, aged sixty-seven. The signs of the neoplasm appeared six weeks after the limb was injured by falling coal. Amputation of the thigh was successfully performed.

Unilateral Progressive Facial Atrophy.—Dr. SUCKLING introduced a woman aged forty-two suffering from this affection. It commenced gradually when she was about eighteen years of age, the left side of the face being at that time noticed to be different from the right. The bones were atrophied on the left side; the horizontal ramus of the inferior maxilla was an inch shorter on the left than on the right side; the fat had almost completely disappeared, the eyeball being retracted and there being deep fossæ above and below the zygoma. The hair had disappeared over the left half of the front of the skull. There were two well-marked grooves on the left side of the forehead in the situation of the supra-orbital and supra-trochlear nerves. The temperature of the left side of the face was a degree higher than the right; sensation was unaffected and the general health unimpaired.

Cholecystotomy.—Mr. HASLAM showed some gall-stones that he had removed by cholecystotomy from a patient aged thirty-six. She had been suffering from jaundice, from obstruction to the bile-duct, and pain in the hepatic region, with emaciation, for nearly four months; the gall-bladder was much distended, and on opening this 223 stones were removed, several of the largest being nearly an inch in diameter. The incision into the gall-bladder was stitched to the margin of the wound; the operation gave great relief from the pain, but the obstruction was entirely unrelieved, no bile whatever being discharged from the fistula. She lived only two months, and on post-mortem examination the liver was found to be studded with malignant deposit, and the ducts in the transverse fissure completely blocked by new growth.

Malformation of Intestine.—Mr. WILLIAM THOMAS exhibited the stomach and intestines of an infant five days old, that had been operated on for obstruction. The stomach was of normal size; the duodenum became gradually enlarged as it reached its termination; the jejunum was very large, and formed dilated coils, which had distended the abdomen. It had been opened twenty-two inches from the pylorus for the relief of the obstruction, and ten inches further terminated in a blind extremity. The small intestine recommenced almost immediately between the layers of the mesentery, being about the size of an ordinary pencil; it formed several coils, and, extending for thirty-six inches, terminated in a well-formed cæcum, from which a perfect though contracted colon could be traced to the anus. The various parts of the intestine were so firmly matted together by well-organised bands of lymph, the result of previous intra-uterine peritonitis, that the relations of the parts could not be made out until the intestines were removed from the abdomen. The child was somewhat relieved by the operation, and lived for about eighteen hours after it.

Excision of Superior Maxilla.—Mr. BENNETT MAY exhibited specimens from recent cases of excision of the upper jaw; and a patient, a young woman, on whom he had recently performed the same operation for an osseous tumour.

Mr. LAWSON TAIT read a paper on the Operative Treatment of Peritonitis.

Reviews and Notices of Books.

Bright's Disease and Allied Affections of the Kidneys. By CHARLES W. PURDY, M.D., Professor of Genito-Urinary and Renal Diseases in the Chicago Polyclinic. London: H. K. Lewis. 1886.

THIS is a very good and readable book, written by one who evidently has thought deeply and studied closely the subject in hand. Dr. Purdy, before bringing his work to completion, visited Europe, and made himself acquainted with the views held by the foremost renal pathologists in this country and abroad. Thus, in England he spent a considerable time working in the pathological laboratory at Aberdeen with Professor Hamilton; at Edinburgh he attended the clinique of Professor Grainger Stewart; he visited Manchester in order to make himself acquainted with Sir William Roberts' views; in London for the same purpose he attended the hospitals visited by Drs. George Johnson, Dickinson, and Ralfe; whilst he made a special journey to Harrogate in order to become practically acquainted with Dr. Oliver's methods of urine testing, which were then beginning to attract attention. Such industry and earnestness of purpose have met their reward in the firm grip which the author has manifestly acquired of the various theories and practice of the different schools of renal pathology now existing, which enables him to state the various propositions tersely and correctly, and also helps him to a right judgment thereon. But not only has Dr. Purdy made himself per-

sonally acquainted with the teaching of the different schools; he has also kept himself well abreast of current European literature up to the very date of publication. It must not, however, be supposed that the book is nothing but a mere collection of opinions; the author has views of his own, which he asserts modestly but firmly, whilst he has always a decisive word to say on any point he may happen to be discussing.

The first chapter deals with the nature and character of the different forms of albuminuria, which he divides into false and true—we prefer the terms functional and organic to distinguish between the albuminuria resulting from changes in blood or disturbance of the circulation, and that caused by organic disease of the kidneys themselves. He particularly emphasises the fact that intermittent albuminuria is common in the most grave of all forms of renal disease—viz., renal cirrhosis,—and that the fact of the albuminuria being intermittent is no reason for assuming that it is due to disturbance of function, and not to organic disease. This is a very important caution, because the tendency at the present time is undoubtedly to consider all irregular forms of albuminuria as purely functional, and therefore comparatively unimportant. The observations on the rival methods of testing for albumen in the urine are clear and to the point. The second chapter deals with the much vexed question of uræmia, and the most recent views are plainly stated. Speaking of the treatment of this condition, Dr. Purdy mentions among many other modes of treatment the practice, originally suggested by Scanzoni, of administering morphia subcutaneously for the relief of acute uræmic convulsions. Dr. Loomis of New York has recently revived this practice, and demonstrated that morphia can not only be used in these cases, but also with the happiest results in, arresting the muscular spasms, by establishing profuse diaphoresis and by facilitating the action of cathartics and diuretics, especially the diuretic action of digitalis. The range, utility, and safety of morphia in uræmia must be strictly confined to the acute convulsive seizures; its employment is improper in a state of pure coma, or chronic uræmia unassociated with convulsions. Chapters III. and IV. are devoted to the consideration of acute and chronic nephritis and renal cirrhosis, the pathology of the various conditions being illustrated by some exceedingly well executed engravings, which, unlike what we meet with in American editions generally, are original, and not taken secondhand (often without acknowledgment) from the work of some standard English author. The concluding chapters deal with the etiological varieties of nephritis—scarlatinal, puerperal, lardaceous, and cardiac. We regard the chapter on puerperal nephritis as a valuable contribution on a subject about which little is yet known, and which has not been studied with the attention it deserves.

In conclusion, we can heartily recommend this work. On its own merits it will find a worthy place among its contemporaries dealing with the same subject; and it will, from its thoroughness, simplicity, and clearness, attract readers who wish to make themselves acquainted with the most recent advances of renal pathology and therapeutics.

Annual Report of the Board of Works for the St. Giles's District.

THIS report consists of three parts, the first, by the clerk, being almost entirely limited to giving an account of recent legislation and to its application to local conditions. But with reference to Shelton-street area, which had been reported by Mr. Lovett, medical officer of health, to the Metropolitan Board of Works, he states that that Board had taken no action thereon. Subsequently the Home Secretary, accompanied by Mr. Stuart Wortley, M.P., inspected the area, and informed the Metropolitan Board that he endorsed Mr. Cubitt Nichols' report that the area should be dealt with under the Artisans and Labourers' Dwellings Improvement Act of 1875. This Board then referred the subject to a committee with the intention of the area being again viewed, but up to June of the present year nothing further had been done. The second part of the report deals with matters that came under the control of the surveyor, while the third part contains the report of the medical officer of health for the year ending Jan. 2nd, 1886. This report shows that the improvements which have been effected through the action of Mr. Lovett and his predecessors are still continued; as many as twenty-eight houses were reported under the Artisans and Labourers' Dwellings Act of 1868, the whole of this number being situated in Dudley-street. Altogether, Mr. Lovett says, "238 houses have been condemned by my late predecessor and myself, of which 152 have been demolished," affording good evidence of the results that follow where an efficient medical officer of health is supported by an intelligent authority. The death-rate of this district was 23·6 per 1000 of population, being almost identical with that of the decennial average. The whole district is, however, divided into three sub-registration districts, the death-rate being in St. George's (Bloomsbury) 18 per 1000, in St. Giles's (South) 34·5 per 1000, and in St. Giles's (North) 18·1 per 1000. The high death-rate in St. Giles's (South) receives some explanation from the large proportion of births in this sub-registration district, which amounted to 42·8 per 1000 of population, the rates in St. George (Bloomsbury) and St. Giles's (North) being 21·8 and 23·0 per 1000 respectively, giving a rate for the entire district of 29·1 per 1000. The death-rate in the Peabody Buildings was as high as 24·0 per 1000; and here the birth-rate was 53·8 per 1000. The zymotic death-rate in the whole district was 2·3 per 1000; scarlet fever was notably absent; enteric fever caused but ten deaths, while no case of typhus fever was known to have occurred during the year. Mr. Lovett comments on the fact that typhus used periodically to break out amongst the inhabitants of the courts and alleys in Great Wild-street and Great Coram-street, but since those areas have been cleared of their insanitary dwellings and new model buildings erected in their stead, this form of malignant fever has been absent from the district. This is a matter which concerns other districts than that of Mr. Lovett's, and all London may be grateful to St. Giles's and its officers for the benefit they have conferred on the metropolis.

The Hospital, Part 1, Vol. I.

We have received the first monthly part of *The Hospital*, which is described on the title page as "an Institution, Family, and Parochial Journal of Hospitals, Asylums, and all Agencies for the Care of the Sick, Criticism and News." Its policy is thus further indicated in the first editorial article: "It will strive to provide entertaining, instructive, and amusing reading of a popular kind, which will be gathered from the hospital field, using the word hospital in its widest sense, and making it to include all agencies of whatever kind which have for their object the treatment and cure of disease, or the care of the sick and injured all the world over. ..... Indeed, it has been started with the main object of largely increasing the support already given to hospitals, by awakening a personal and sustained interest in the work which they undoubtedly do for the whole community, and for each individual, from the highest to the lowest." Whilst, therefore, the single goal which this new journal desires to reach is the interests of the hospitals, it has, in order to attain it, to travel over wide and varied tracts of ground. Thus there are articles devoted to "Hospital Worthies" (the first of which consists of an appreciative

notice of the work done on behalf of the hospitals by Sir Dr. Wakley), to "Hospital Administration," to "The Story of the Hospitals"; there are "Notes and News," "Words of Consolation," "Prize Competitions," "*The Hospital* Charity Box," "The Children's Corner," and a serial story. An in-patient's and out-patient's hospital diary is also given. The work is of a popular nature and accomplished with enterprise and ability, and we trust that its founders will be successful in their advocacy of the great cause of the hospitals. *The Hospital* is also published as a weekly paper, last week's issue containing a short article by H.R.H. the Duke of Cambridge on the "Importance of Maintaining Medical Charities."

The Asclepiad, No. 12, Vol. III.

THE current number ends the third volume. Some practical notes on the Diagnosis and on the Ammonia Treatment of Fibrinous Obstructions of the Vascular System constitute a clinical review of thirty-six years of personal observation by Dr. Richardson. The reader will find here an instructive account of the subject in a readable form. But we do not think the author has succeeded in lighting up the dark parts of the field of diagnosis of this condition of fibrinous obstruction of the cardiac cavities. The physiology of historical repetitions is that kind of subject to which Dr. Richardson's genius naturally turns. Ambrose Paré and the Birth of French Surgery (with portrait) is excellent; so are also the Opuscula Practica. The Transmutation of Blood under Electrical Vibration requires the use of the term "transcendental," but not necessarily in a condemnatory sense.

Analytical Records.

VAPOUR CONES.

(NORTH HANTS CHEMICAL COMPANY.)

WE have examined and experimented with a large number of these vapour cones. There can be no doubt that the cones increase the number of effective agents available for sanitary and medical purposes. The cones naturally fall into three or more different classes, according to the materials with which they are provided, to the purposes they have in view, and to the efficiency with which their objects are carried out. A certain class of the cones are employed for perfuming purposes. Of this series we have tried the white rose and patchouli and they answered their purpose admirably. The "oxygen" cone we tested in the following manner. The contents of a close stool were exposed to the atmosphere of a small watercloset, the vapour cone was lighted, and the window and door shut; the closet was visited in thirty minutes, and without the observer perceiving any objectionable odour. The sulphurous acid cone is a more convenient method of fumigating a room with sulphur than the ordinary method in use. We have also experimented with carbolic acid, with aromatic acetic acid and carbolic acid, and with carbolic acid, camphor, and lavender. These cones yielded a very abundant supply of vapour, which appeared to possess all the properties of vapours produced by other modes in common use. The great heat evolved by the vapour cones did not in any of our experiments cause a decomposition of the material vaporised. The cerebene cone is also a good one. The calomel cone certainly has many advantages over the ordinary method in use for administering a calomel bath. That the cones will prove of excellent service as deodorants, disinfectants, and fumigants there cannot be any doubt. The majority of the cones meant for medical purposes do not, however, appear to us to be possessed of properties superior to those methods of steam or hand spraying or inhalations already in use, though they cannot be regarded as inferior in point of quality and quantity of vapour supplied.

MEDICATED SOAPS.

(THE MILTON CHEMICAL COMPANY, BATH-STREET, GLASGOW.)

Several samples of soap manufactured by the above company have been examined by us and submitted to partial analysis. They are described with perfect correctness as iodoform soap, corrosive sublimate soap, blue gum-tree soap, and Yara-Yara perfumed soap. In each the basis is a neutral transparent soap of good quality. The iodoform soap is most obviously genuine, for the yellow scales shine through the clear soap. It should be most valuable in eczema and other skin diseases. The blue gum soap contains the fragrant eucalyptus oil, which is easily isolated by distillation with water. The Yara-Yara soap is similar, with the powerful and delicate odour of the oil. It is an admirable toilet soap.

BISHOP'S GRANULAR EFFERVESCENT HYDROBROMATE OF CAFFEINE.

(BURROUGHS, WELLCOME, & CO., HOLBORN VIADUCT.)

An interesting and well-made preparation, in which the active principle of tea and coffee (caffeine being, as is well known, the alkaloid common to both) is presented in combination with hydrobromic acid. The idea is to unite as cerebral stimulants and tonics the virtues of tea or coffee with those of the alkaline bromides. Analysis readily shows the presence of both the essential ingredients. The caffeine, extracted by sodic carbonate and chloroform, crystallises in the well-known feathery tufts. The preparation is certainly very valuable, and deserves careful trial in cases of mental exhaustion, nervous headache, and the like.

BROMO-CAFFEINE.

(CORBYN, STACEY, & CO., HIGH HOLBORN.)

This preparation appears to be substantially identical with the last. It contains both caffeine and hydrobromic acid, or rather the hydrobromate of the base, and in excellence of manufacture it leaves nothing to desire. We do not doubt that it will receive the attention of the medical profession.

HAY'S AERATED HOP ALE (NON-INTOXICATING).

(WILLIAM HAY, HULL.)

This is an excellent non-alcoholic beverage, which probably approaches as near to beer as is possible without the presence of alcohol. Our analysis showed the presence of the bitter principle of the hop in perfect solution.

HAY'S ORANGE QUININE TONIC.

(WILLIAM HAY, HULL.)

This is a good preparation, but we do not find in it any peculiarity that calls for remark. The presence of quinine is shown by the ordinary tests, and also by the characteristic fluorescence.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—A quarterly meeting of this Association was held in the Hall of the Royal College of Physicians, Edinburgh, on Thursday, Nov. 11th. Dr. Byrom Bramwell showed a collection of photographs of brains in section and whole, and explained his speedy method of making microscopical examinations of that organ. Dr. Rorie (Dundee Royal Asylum) read a paper on the Recorded Treatment of the Insane sixty years ago, as illustrated by the Records of the Dundee Asylum; Dr. Maclaren (Stirling District Asylum) read a Psychological Study of Louis XVI.; Dr. Campbell Clark followed with details of an Asylum Service Provident Scheme, and Dr. Urquhart (Perth Royal Asylum) read notes of two cases of Syphilitic Insanity. There was a very good attendance of members, and considerable discussion was evoked by the papers read. In the evening the Association dined in the Edinburgh Hotel. The next quarterly meeting in Scotland will be held in the Hall of the Faculty of Physicians and Surgeons in Glasgow on the second Thursday of March.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 20, 1886.

IN another column we give an account of a meeting, which was held on Tuesday in the Hall of the Society of Apothecaries, on the subject of the amalgamation of the Examining Board of the Society with that of some other medical institution having the power of granting diplomas in accordance with the new Act of 1886. The meeting was convened by the Master of the Society, but was by no means limited to its members; it may therefore be taken to fairly represent the large body of general practitioners upon whom the public have to depend whenever they have occasion to seek medical aid. The proceedings at this meeting are instructive. The Master, who presided, explained the course the Society had adopted in accordance with the provisions of the new Medical Act—a course which shows abundantly the desire of the Society to loyally carry into effect the intentions of the Act: that the serious disadvantage of the existence of rival examining bodies in the metroplis should be obviated. The Society has thus far behaved in a manner which will commend it to the profession on the one hand, and on the other to the public, in whose interest the law of the present year has been passed. In striking contrast is the conduct of the two corporate bodies, to which the Society has fruitlessly addressed itself. The Royal Colleges of Physicians and Surgeons have come to the conclusion, or rather the Councils of these bodies have decided, that it is not desirable that their examining boards should amalgamate with that of the Apothecaries' Society; and this in direct opposition to the recently expressed wish of a large number of the Members of the latter College. No reason touching the main question is given, and the joint communication, which the Society has received, was placed in its possession but an hour before the meeting on Tuesday was held, and some four months after the request had been made to the Colleges. The report which we give of this meeting may be taken as affording evidence of the judgment which the profession will pass upon the conduct of the Colleges, the result of which is that one of the primary objects of the Act has been rendered null and void, and that the hope that has been entertained that rival examining bodies would no longer exist in London has been grievously disappointed. We do not hesitate to express the opinion that the Colleges have, through their Councils, inflicted an almost irreparable injury on the profession, and have placed the public under serious disadvantage. The Apothecaries' Society has nothing to gain as a Society from the desired amalgamation; it has, indeed, much to lose; nevertheless, it has itself taken the initiative in conforming to the requirements of the recent Act. The Colleges are differently placed; their position in guarding at the same time the interests of the public and of the profession would have been materially strengthened by an alliance with a Society possessing important and independent rights, while their control of all essentials in examinations would have been preserved, as may be seen by the tenour of the letter which the Society has addressed to them.

It is, then, no matter for surprise that the speakers at the meeting betrayed some exultation over the strengthened position which the Society now occupies, although the meeting as a whole deplored the contempt shown for the welfare of the public. Its continuance as an independent examining body is ensured; it will doubtless go through the form of addressing itself to other licensing bodies, and it will experience no discouragement from the successive refusals which it may meet. Finally, it will appeal to the Medical Council, and, if necessary, to the Privy Council, who will accord to it all the rights necessary to conduct independent examinations. The Society will then set itself to work to determine its future, over which it will have complete mastery. It will become a necessity to a large number of medical men whose aim in life will be to fulfil the requirements of an important section of the community, and it will protect the interests of its licentiates by exercising its power of prosecuting illegal practitioners.

THE letters which have lately appeared in our columns on the artificial feeding of infants show the great divergence of opinion which exists amongst practical and enlightened members of our profession on this most vital subject. The poor mother, unable to suckle her infant, has not alone to face the conflicting instructions of doctor and nurse—the first clinging tenaciously to his physiological doctrines in spite of the screams of the infant and its non-increase in weight, and the second maintaining the excellence of her patent foods and of her various "thickenings," regardless of the future rickets in store for the luckless child. But when doctors disagree, and especially doctors who speak with the authority of experience, the mother's bewilderment may well be great, and she is either tempted to fall back on the time-honoured rule of thumb, or take refuge in the hypothesis of compromise that the proper course lies sometimes with one, sometimes with the other, and sometimes between the two. We shall not presume to adjudicate between the diverging views of our correspondents. With the limited knowledge at present available on the subject, they seem to us alike too sweeping and dogmatic for universal acceptance. Let us attempt the humbler task of indicating some simple homely tests which ought to be applied in any given case before we conclude that the method which has been adopted in that case is a satisfactory one.

The first test depends on the quiet and comfort of the child and the increase in body weight. This increase ought to be from three to four ounces weekly or more. The weight test is, however, by no means conclusive if taken alone. Many a hand-fed child when twelve months old is fat and plump, but is found to be rickety to an extreme degree; and it is well known to experienced nurses that breast-fed healthy infants are often much less stout than those which are reared by hand. The advocate of any given method will not therefore settle the matter by simple weighings, although these count for a great deal.

The second test depends on the examination of the

fæces. With regard to the frequency, there is a common belief that four to six is the proper number of daily evacuations for an infant during the early months of its existence. We hold this to be a mistake. Healthy breast-fed infants often pass not more than two stools a day after the first fortnight, and satisfactory hand-feeding ought to aim at a similar result. We hold that there is a presumption that an infant who passes regularly from four to six stools daily is passing a great deal of undigested food, and that so far the alimentation is imperfect. The wholesome fæces of a healthy breast-fed infant are of a bright gamboge-yellow, they are not unduly offensive, and they present very scanty traces of undigested casein. Now, in the majority of infants brought up on cow's milk, even diluted to the starvation point, the stools are distinctly offensive, and are largely made up of masses of white casein. When this occurs, to find fault with the liver and do nothing more than prescribe the inevitable grey powder appears to us the most absolute empiricism, and the antiseptic cleansing of feeding-bottles and the banishment of tubes, excellent as these measures undoubtedly are, will not solve the difficulty in question.

How can the casein be dealt with? There are several methods open to us. First, it may be predigested wholly or in part. The simplest and readiest way of accomplishing this has, in our experience, been brought about by the use of one of the preparations suggested by Sir WILLIAM ROBERTS, which, made with fresh milk, is practically a partly digested milk gruel. But it is doubtful whether this method, invaluable as we believe it to be in selected cases, ought to be tried as the first routine step in dealing with the difficulty in question.

Sir WILLIAM ROBERTS, in his lectures at the College of Physicians, referred to an observation of his own made whilst feeding a healthy kitten exclusively on predigested food. Without obvious or marked departure from health, the kitten nevertheless, in respect of body weight, fell behind another kitten fed on milk. It was suggested that some atrophy of unemployed glands might be responsible indirectly for this failure in nutrition. Now, in our problem, if we can get the infantile alimentary tract to digest for itself the casein masses, more will be gained than if the casein be predigested.

A simple, time-honoured method, which we think ought always to be tried, is the dilution of the milk in varying proportions with barley-water, which perhaps in a mechanical way facilitates the separation of the curd into more manageable masses. If this is found unsatisfactory, a very little malted food ought, we think, to be added to each bottle. That the whole character of the stools in respect of undigested casein may become altered after the adoption of this simple expedient we have satisfied ourselves again and again, as well as of the diminution in the actual number of the evacuations. But our physiological friends protest that this is using farinaceous food, that the infant's pancreas and salivary glands are rudimentary, and that its economy is unequal to the conversion of starch. To this objection there are several answers to be made. First, physiologically it is by no means proved that the sole agents in the conversion of starch are the pancreas and the salivary glands, and experiments to prove the absolute incapacity of the infantile alimentary tract to convert a small amount of starch are not forthcoming. Again, in a good malted food a great part of the starch has been already converted and rendered soluble. But let it be granted that even after boiling there is a small amount of unaltered starch; if the net result is that the fæces of the child are more wholesome and less frequent, that it does not suffer from vomiting, acidity, and flatulence, and that it is gaining weight, what evidence is there that the small amount of starch has done harm?

The employment of the term "farinaceous" has, indeed, brought us more or less under bondage in our directions as to infant feeding. To repeated meals of arrowroot, cornflour, baked flour, and the like, even when made with milk, the term farinaceous is properly applicable, and we are second to none in our condemnation of such methods of feeding infants; but a broad distinction ought to be drawn between them and the use of a very small quantity of malted soluble food added to milk. If even the malted foods be used in large relative proportion in early infancy, to the exclusion or great diminution of the quantity of fresh milk, we believe that serious risk is incurred in the direction of scurvy; and this is the more insidious because, with regard to the two tests which we have mentioned, the body weight may certainly increase, and the stools may be less offensive and less frequent than under a milk regimen. The proper use of the malted foods is that they should be employed in small quantity—not in any sense as a substitute for fresh milk, but as an aid to the digestion of the casein.

We have said nothing about the humanised milk and the cream and whey methods. Useful as these plans have unquestionably proved hitherto, they have been methods for the rich and not for the poor, and their discussion may be for the present deferred.

THE Medical Council met, we may hope for the last time in its imperfect form, on Tuesday last. The time, as we pointed out last week, is highly inconvenient. We are in the very middle of a general election by the profession. The voting papers which are to determine the election are coming in daily in hundreds, if not thousands, and this in a comparatively unprotected form. The most that can be hoped for is that the Registrar, whose time is fully occupied by Council business while the Council is sitting, will carefully receive and guard them until the 22nd, after which the serious work of counting will have to be done. Not only to the officials of the Council must this time for the meeting be very trying, but to the members. Many of these are engaged as teachers in distant cities of the kingdom, and to bring them to town in these dark days of winter must be very inconvenient. Probably the chief argument of those who defend the calling together of the Council at this time is that it is necessary in order to purge the Register of the new year of names that would discredit it. We see nothing else to constitute a justification of the meeting at present. But for this purpose a meeting before or after the election of Direct Representatives would have been quite sufficient. Be this as it may, almost the first work of the meeting was to pass a resolution ordering the erasure of the name of MR. EDWIN WM. ALABONE from the Register. This subject was brought before the Council in the ordinary way by a communication from the Royal College

of Surgeons of England, enclosing a resolution of the Council of the College, which will be seen in our report, and also by a communication from Mr. ALABONE himself to the Registrar, saying that he would be obliged if the Registrar would kindly erase his name from the Register. This is decidedly unusual, and we may take it as an admission on the part of Mr. ALABONE that his conduct was thoroughly indefensible. We have already expressed our opinion of Mr. ALABONE'S case, and have no wish to make his situation worse by further reflections of ours. His fate may be a warning to others that members of medical and surgical corporations are still bound by their own declarations and by the very nature of their position to "demean themselves honourably" and to maintain the dignity and welfare of the profession, and that failure in these undertakings or the open disregard of them may leave the bodies from which their diplomas are derived no alternative but to withdraw them.

A more difficult case for the judicial consideration of the Council, and one of immense importance to the profession, came up on the first day of the sitting, in the shape of communications laid before it by the Executive Committee. These had reference to a case which our readers will remember, in which an inquest was held on a man named GEORGE WADLEY, attended by Mr. DAY and his unqualified assistant, Mr. DAVENPORT. Mr. DAY signed the certificate of death, having once seen the man two days before his decease. The friends said the deceased had generally consulted Mr. DAVENPORT, and that they had always considered him a medical man who could give a certificate. The case came to the Medical Council from the Home Secretary, whose attention was drawn to it by Mr. A. BRAXTON HICKS, Deputy Coroner for Westminster. The Home Secretary first referred the case to the Registrar-General, who thought Mr. DAY entitled to grant a certificate, but considered that Mr. DAVENPORT should be dealt with by the Medical Council. The Medical Council thought the only person they had to deal with in these cases was the registered principal under whom the unqualified assistant acted, and on this view referred the matter for the present for investigation by the Branch Council for England. Here the matter will for a time rest; but the important thing for medical men to notice is that for the second time, and in a different Government, the Home Secretary has referred these cases to the Medical Council. The Medical Council, too, should take this fact into more consideration. We are in no way prejudging the present case; but the class of cases of which it is one is very large, and it is idle to think that the Medical Council can much longer refuse to take serious notice of them. All those who have valid and substantial facts illustrating the system by which branch dispensaries are practically left in charge of unqualified assistants, under cover of the name of a qualified principal, would do well now to communicate them to the Executive Committee of the Medical Council, who have received authority from the Council to communicate with the Home Secretary on the subject.

The second day (Wednesday) of the Council's sitting was mainly occupied by a discussion which might have been deferred till the Direct Representatives of the profession were elected, and which ought to have been so deferred. It had reference to the lengthening of the term of the medical curriculum on a proposal by Dr. MCVAIL to make the course of medical study after registration five years if the subjects of Elementary Physics, Chemistry, and Biology are included in that period. If the time of medical study is to be extended—and there is much to be said for this, as both Dr. MCVAIL and Dr. BANKS (the new member of the Council, as representative of the Victoria University), in an able maiden speech, showed—it is but fair to give the new representatives an opportunity of giving their opinions as to the best way of using the additional time. Besides, this very motion, or a similar one, had been passed only last year by the Medical Council, with no obvious effect up to the present time. It is this habit of the Council of discussing the same subject over and over again at short intervals which irritates the Examining Bodies and does not excite the respect of the profession.

THE clinical history combined with the post-mortem examination of the case of Measles and Myelitis related to the Royal Medical and Chirurgical Society by Dr. T. BARLOW at its last meeting constitutes a record of facts of which the neurology of fevers stood much in need. The course of the clinical history pointing to the spinal cord as the seat of the lesion was fully explained by the discovery after death of an inflammation that seemed certainly related to primary vascular disorder. That is a solid fact which may be employed for deductive purposes in other cases of the kind, whether fatal or less severe. It is plain, then, that measles does not preclude the possibility of myelitis. The two processes have worked together in the same organism. That they do not frequently coexist may be regarded as an argument against Dr. BARLOW'S view that the myelitis was as much a part of the measles as the skin rash and the bronchial catarrh. But the definitive settlement of the etiological question appears, indeed, to be yet far from being attained. If we gathered the threads of Dr. BARLOW'S case aright, there was nothing very remarkable in the appearance of the other phenomena of measles. It seems rather inexplicable, therefore, that the spinal cord should, so far as the measles was concerned, be the seat of an exanthematic vascular eruption. The spinal cord is of ectodermic origin, and if measles chooses for its *lieu d'élection* this set of tissues and those of hypoblastic origin too, we might see some force in the belief that the myelitis was as much a part of the measles as the skin rash and the bronchial catarrh. It is not thoroughly known whether the severe measles of Fiji is attended with spinal lesions; but it is certain that malignant measles, or any malignant acute specific fever, is accompanied by grave cerebro-spinal disturbance. The necropsy of such cases reveals great vascular engorgement of the nervous centres; but this fact is, rightly or wrongly ignored—at least as an argument that the measles "came out" in the deeper parts of the epiblast rather than in the more superficial. The pathology of the measles eruption, however, is not yet fully understood. Is it due to a topical action of the measles poison? or does the rash depend on some trophic disturbance of nerve centres? May not the cause of measles produce the cutaneous eruption by virtue of some action on the nervous centres? In malignant cases there is purpura.

Is this purpura the equivalent, only in a more severe degree, of the papular eruption? It is no argument against the view to urge that the measles papule may be present side by side with the purpura; nor indeed to argue that, as the purpura appears earlier than the papules, therefore they cannot own the same cause; for it is conceivable that a poison acting with greater intensity may both alter the character of its effects and cause those effects to appear sooner. But we must not leave out of sight the other facts of the case described by Dr. BARLOW. The occurrence of measles in adult life, as also the fact that the man was an active member of the police force, and therefore exposed to the action of the weather—and this whilst the measles was incubating, and indeed actually evolving, for the man continued at work till the appearance of the rash,—render it possible that the myelitis accompanying the measles may have been at least partially caused by these somewhat unusual circumstances. Dr. BARLOW, indeed, admitted that such might have been the case, though he also mentioned that a brother policeman of his patient contracted the disease, which ran a usual course, without spinal symptoms. But we have pursued the possibilities of the case sufficiently far. Thanks to Dr. BARLOW, science has become possessed of a definite fact regarding the nature of spinal lesions which may occur in the course of measles. Such vascular lesions have been also discovered in small-pox by WESTPHAL. Now it does not follow that all paralyses occurring in the course of acute specific fevers are manifestations of spinal vascular lesions, and still less does it follow that the post-febrile nervous disorders have such a pathology. Indeed, when a considerable interval elapses before the gradual onset of nervous symptoms, we may reasonably conclude that the lesion is not a vascular one.

Whilst we may freely admit the etiological influence of acute specific fevers in the causation of paralysis, we must also confess that the already ascertained clinical facts do not yet receive that elucidation from pathological anatomy which is their scientific need. The suggestion that cases of acute ascending paralysis in which no lesion can be found may be due to the influence of an autogenetic alkaloid having paralysing effects on the spinal or peripheral nerve motors is a good one, though not one that satisfies the mind of the pathologist.

Annotations.

"Ne quid nimis."

THE IMPENDING ELECTION.

THE arrangements for the election are more or less complete. In Scotland and Ireland we understand the arrangements include provision for the admission at the counting either of candidates or of the agents or friends of candidates. In England the Branch Council has not seen its way to do this. The members of the Branch Council are quite satisfied that the method they have adopted will secure fair play and proper care. And nobody will doubt the desire of the Council on these points. But we strongly urge upon them the admission of representatives of the candidates. It is obvious that only three out of the fourteen candidates can be satisfied with the result. The others ought at least to be satisfied with the methods and the details of the process of election. We are glad to hear that plenty of counters are to be engaged and that the work of counting is likely to be completed quickly. The officials of the Council, who are much pressed with this business and with the work incident to the meeting of the Council, will have need of much extra help. But obviously the result of the election should be announced as soon as possible.

POLLING THE FELLOWS OF THE COLLEGE OF SURGEONS.

AT the ordinary meeting of the Council of the College of Surgeons held on the 11th inst., it was decided to poll the Fellows in order to learn authoritatively how far they are favourable to the admission of Members of the College (*a*) to vote for Fellows as members of the Council, and (*b*) to a seat on the Council. We must congratulate the Council on their concession, tardy though it is. Hitherto they have not deemed it expedient to grant either of these two points, chiefly on the grounds that it is neither wise on behalf of the College, nor just to the Fellows themselves, "by whom alone they have been elected to office as the governing body of the College," to diminish the privileges and status of the Fellowship. These arguments are specious rather than forcible, and savour of the ultra-conservatism which has so long characterised the proceedings of the Council. We shall look forward with confidence to the result of this poll, hardly doubting that the majority of the Fellows will be in favour of the two proposals. For our own part, we quite fail to see how the privilege of voting is lessened by being shared with others, and how the academic status of the Fellowship will be endangered by allowing Members to take part in the management of the College. So far, it is the Council who have lowered the academic status of the Fellowship, and who propose still further to widen the basis and facilitate the acquisition of this diploma. They have gone so far in this direction that, at the general meeting on the 4th inst., a resolution was passed by the Fellows and Members practically declining the distinction on the terms proposed. Fellows will do wisely to vote in favour of the two proposals, if only in order to bring the present deadlock to an end, for the Council will not be able to obtain the alterations in the Charters which they desire in the face of the organised opposition of the Members at large. Until they do so Fellows will not secure the proxy voting, which is one of the objects sought by the Council in their proposed new Charter.

MUSCULAR PERCUSSION REFLEX AS A METHOD OF CLINICAL INVESTIGATION.

WHEN the chest wall is subjected to a tolerably smart blow with the finger or percussion hammer, an elliptical elevation of the surface may frequently be observed for a few moments after the blow. This fact, which has been remarked by Mr. Lawson Tait, Dr. James Ross of Manchester, and others, has acquired some importance from the somewhat analogous observations of Westphal, Erb, and others on the tendon, osteal, periosteal, and muscular percussion reactions. Quite recently, too, a Russian author (Dr. V. V. Philipovich of Odessa) has investigated the conditions under which the phenomenon is produced showing that it may be made available like other reflexes for diagnostic and clinical purposes. In his observations he made use of a percussion hammer furnished with a spring and an index by means of which the force of each blow was registered. The pectoral regions of 100 presumably healthy young men were examined. The lowest force required to produce the phenomenon—which, by the way, Dr. Philipovich proposes to style "loco-tetanus," instead of "idio-muscular contraction," the term used by Dr. Ross—was 400 grammes, and the

highest 2000 grammes. On analysing the observations, it was evident that the lower degrees of force were invariably sufficient in weakly and ill-formed subjects who had been either permanently or temporarily rejected by the recruiting authorities. Still lower figures were obtained on the examination of diseased persons, the lowest of all being afforded by phthisical patients. In all chest cases it was noticed that the "loco-tetanus" was more easily produced on the side where the disease was situated, or on that where it was the more extensive; thus in a case of dry pleurisy of the right side the figures obtained were—for the sound side, 550 grammes, and for the diseased side 150 grammes. The mean force required in the 100 healthy subjects was 750 grammes on the right side and 850 grammes on the left; and as the limit of that which could usually be borne painlessly by healthy persons with the instrument used (the head of which was a metal ball covered with gutta-percha) was about 700 grammes, it may be roughly assumed that if the contraction can be produced by a tap, the force of which is much below that which is sufficient to cause pain in a healthy subject, some pathological condition is probably present, or at least that the general state is below that of a vigorous man.

THE DISTINGUISHED SERVICE ORDER.

THE *Gazette* of Nov. 6th contains a notification of the creation by Her Majesty of a naval and military order of distinction under the title of "Distinguished Service Order." It has been founded "for the purpose of rewarding individual instances of meritorious or distinguished services in war," for which the means in existence are stated to be limited. We do not propose to discuss the question whether this multiplication of honorary distinctions for a zealous and efficient discharge of duty has not been carried to an injudicious length, or whether it may not be deemed evidence of the decadence of that grand old patriotic feeling by which our officers—naval and military—used to be actuated, and which produced heroes of whom the nation may well be proud. But accepting it as one of the changes which, for good or for evil, have been introduced into the naval and military services in our days, we find serious objections to the conditions on which this distinction is to be conferred. It is to be confined to commissioned officers whose "services shall have been marked by the especial mention of his name by the admiral or senior naval officer commanding a squadron or detached naval force, or by the Commander-in-Chief of the forces in the field, in despatches for meritorious or distinguished service in the field or before the enemy." This is quite in accordance with the military traditions which ignore all service but that in front of the enemy, and regard bulldog courage as the highest qualification in an officer. The meritorious work by which an army is maintained in a state of efficiency, the arduous services rendered at the base of operations by the officers in command of the depôt, the medical officers in charge of hospitals, and the officers entrusted with the important duty of providing the necessary supplies, are entirely ignored, and that alone is to be considered "distinguished or meritorious" which is performed in the field under the eye of the Commander-in-Chief. And yet how much of the success of a campaign depends upon the efficiency of the work done by these ignored branches, and when any hitch occurs how speedily are they remembered in the distribution of censure—often upon very insufficient grounds. We have always held, as regards medical officers, that the rewards conferred upon them for professional work have been very inadequate to the labour and responsibility involved in the efficient performance of it—in fact, have scarcely existed. We cannot but regret that in instituting a "Distinguished Service Order" Her Majesty has not been advised to make provision for the reward of medical officers who perform meritorious or distinguished service in the conflict with epidemics, and with those diseases which extinguish an army much more surely than the artillery and rifles of an enemy. A large number of them must be employed under circumstances involving much labour and responsibility, and they are necessarily kept, however unwillingly, in positions which preclude the possibility of this honorary distinction for "meritorious service" being conferred on them, at least under the regulations just promulgated. The limited means of rewarding distinguished services is the reason given for the creation of this new order; surely, judging by the rarity with which such rewards are bestowed, there is no branch of the service to which this description appears to be more justly applicable than to the officers of the Medical Department.

PARKES MEMORIAL PRIZE ESSAY.

IT must be a satisfaction to Dr. Andrew Duncan's numerous friends in England and on the Continent to hear of the generous and hearty welcome accorded to the news of his having been the successful candidate in the competition for the Parkes Prize Essay. All branches of the naval and military services bear ungrudging testimony to his merits and high qualifications, whilst his *confrères* of the Indian Medical Service are pleased that the prize has fallen to a member of their own body. Dr. Duncan has shown himself to be not only a gallant officer in the field—as when he received his wound before Cabul,—but a practical medical officer who thoroughly understands the duties appertaining to camps and campaigns. The establishment of the Parkes Memorial Prize ought to be an inducement for men of first-rate abilities to join the services, since one of the great objections raised by men of that stamp has been hitherto that merit was altogether thrown away in the military and naval service, that a man had no chance of bringing himself forward, and that those alone who took pains to keep in with the authorities had any chance of getting good berths. Much of that is still true; still, however, there is a better chance now of a first-rate man making his mark than when, say, Parkes first retired from the service in despair. The establishment of a medical school at Netley has been a great help to many, and there can be no doubt that the military medical service is gradually becoming more popular, and that an improved stamp of man enters its ranks every year. In order to increase and maintain this popularity it is incumbent on the authorities to encourage especially those officers who show signs of marked ability, and to reward reports of exceptional merit. A little more liberality and foresight in the past would have drawn many men to the service who have hitherto held back, feeling that they might not be permited a free expression of their views in the event of their taking up scientific researches in connexion with their duties.

THE PERILS OF FOOTBALL.

SCARCELY has the football season got into full swing ere our attention is again directed to the very dangerous nature of the game by a sad fatality. Daniel Houghuey, a married man, whilst playing in the Football Cup Tie Match on Saturday last, near Glasgow, between his club, the Mearns Athletics, and the Howood Club, was struck in the abdomen by the knee of an opposing player. Houghney was carried off the field and died on the following day. It is also stated that three other players of the Mearns Club were injured. We are not acquainted with the particulars of this sad case, and do not know whether the play was unduly rough, but we do not hesitate to say that football nowadays too often degenerates into a species of "free fight." The number of broken legs and other accidents already sustained this season bears tribute to this. We have

no wish to see the game done away with. It is enormously popular, and affords recreation and exercise to thousands, many of whom, were football abolished, might spend their spare time in a much worse manner. But we are strongly of opinion that it must be modified. Surely regulations could be devised which, whilst retaining the manly character of the game, would reduce the undue element of danger. It is regrettable that at some schools the playing of football by the boys is made a compulsory matter. At schools the game is played under the best conditions, the masters being able to check any unduly rough play, and the players being boys, not men. But no boy should be compelled to play such a game as football.

MOBILITY OF THE HEART.

DR. M. M. SHERSHEVSKI publishes in the *Vrach* a paper on the mobility or displaceability of the heart. The fact that the heart's position is liable to slight changes according to the position of the body has been recognised by Bamberger, Gerhardt, Luschka, and other observers, but they have none of them formulated the conditions under which it takes place. Dr. Shershevski gives details of the examination of forty persons, all of them free from cardiac and pulmonary affections, in whom he noted accurately the position of the heart's boundaries in the upright dorsal, left lateral, and right lateral positions. The chief mobility was towards the left side, but the heart was often quite perceptibly displaced to the right, as well as downwards and even backwards. The chief conditions under which this occurred were youth, nervous states, and freedom of the vessels from signs of sclerosis. Displacement backwards was found in nearly half the cases, and this shows that the heart ought to be examined in the upright posture. The writer specially remarks on this when the examination is made as a prelude to the administration of chloroform, whereas, as a rule, the stethoscope is applied when the patient is lying down and in a very agitated frame of mind, which latter condition always renders the organ more easily displaced; and the diminished diameter due to this may lead to erroneous conclusions if the measurements be not previously taken in an upright position. This has reference chiefly to young persons. In the case of subjects over sixty years of age, and of much younger persons whose arterial system had already begun to show signs of degeneration, there was little or no displacement produced in any position.

H.M. TROOPSHIP "EUPHRATES."

WITH the arrival at Portsmouth on the 16th inst. of the troopship *Euphrates* the episode of attempted quarantine at Suez of nearly 1300 men, women, and children, in addition to the crew, has come to an end. The British Government having threatened that unless the vessel were allowed to pass through the Suez Canal unhindered she would return down the Red Sea and make her way home by the Cape route, the authorities gave in, and she made her way home without touching anywhere between Suez and Portsmouth. The *Euphrates* left Bombay on Oct. 16th, and on the 18th two soldiers exhibited symptoms of cholera. The official report speaks of the symptoms as mild, but, notwithstanding all efforts to save them, the men died the same day. Every precaution was then taken to stay the spread of the infection, but in the meantime two more deaths occurred—one on the 20th and the other on the 21st. With these deaths the fatal attacks ceased, but two other non-fatal attacks also occurred. After the vessel had passed Perim no further indication of cholera manifested itself, and our Government refused to allow the troops, passengers, and crew to be subjected to the risk of detention at an unhealthy quarantine station on the shores of the Red Sea, where no proper arrangements exist for the decent accommodation of either sick or healthy. The result is that the vessel reached Portsmouth with a clean bill of health, and was at once granted free pratique and entered the harbour. Ample preparations had been made on board the two quarantine vessels stationed at the Mother-bank to receive any sick or suspected cases, had any such existed; but, as is usually the case, a sea-passage on board a healthy and well-kept ship turned out to be the greatest preventive against the spread of cholera. What the result would have been if the alternative method of landing the passengers and crew on the shores of the Red Sea had been adopted may be easily imagined; and we trust that the Government, having once made a precedent of the case of the *Euphrates*, will not again allow the Egyptian Board of Health to interfere with British vessels which, touching at no foreign port on their route, are sailing direct to British ports, where the sanitary authorities should be quite competent to look after their own interests. If the landing of any sick at a quarantine station is held to be requisite by the medical officers in charge of the troops or passengers in their own interests, it is a different matter. But even an infected vessel sailing straight to one of our own ports constitutes no source of danger to other nations, and as such should not come within the jurisdiction of any authority claiming international power.

HOSPITAL AUTHORITIES AND THE INSANE.

THE question has been once more raised whether hospital authorities can be held to be responsible for the safety of persons who having attempted suicide, are successfully treated in the wards or in an emergency room. A case in point has just occurred in connexion with the Middlesex Hospital, to which Arthur Cook Egan, the young man who recently attempted to kill his wife and then committed suicide, was taken after he had previously swallowed laudanum. It should be clearly understood that the officials and authorities of hospitals have no sort of responsibility for the safe custody of persons who are treated on their premises when they recross the threshold. These persons are brought to the hospital sometimes by policemen and sometimes by friends, and after being treated they leave or are taken away. The question now somewhat ungraciously reopened is a very old one, and it cannot be effectively answered without a little plain speaking. The responsible medical officers—we mean the salaried medical or surgical officials of these charities—ought to make it clear to the police and the public, and to coroners, who may perhaps censure them, that they expressly decline all responsibility in the matter. In the days when plainer speaking and more direct action were in fashion, we remember how this question was treated on its merits by more than one spirited official. Nothing so much conduces to the irregular discharge of official duty as the ludicrously short-sighted policy of coroners and juries who cast about censures as carelessly as scandal-mongers scatter aspersions. Let it be once for all understood that, whether the sick, or poisoned, or injured person brought to a hospital for relief be a criminal or a lunatic, the officials of the charity have no sort of concern with anything beyond the limits of their strictly professional duty. If he be criminal, they are neither constables nor gaolers, and he may depart when their work is done. If he be insane, it is not for them to take measures for his being placed in safe custody. Nor will hospital authorities undertake or permit their officers to perform any of the duties which it is sought to impose upon them. This, we take it, is the answer of the medical authorities of hospitals to such riders as that which the jury appended to the verdict in the case of the young man Egan, and it is one which ought to be generally

understood. The simple and sole work of the hospital is to succour the *sick*; the law must provide for anything else that public prudence may demand.

THE LONDON UNIVERSITY CLUB AT MANCHESTER.

THE first annual dinner of the members of the London University Club at Manchester was held on the 13th inst. The Club, which has only recently been formed, has over 100 members, and there was a large attendance at the dinner. Sir Jas. Paget, Vice-Chancellor of the London University, was the guest of the members. The President, Sir H. E. Roscoe, proposed the toast of "The London University," giving a short account of the origin and progress of the institution, to which Sir James Paget responded. Both the proposer and seconder of the toast made some remarks as to the position of the University as a teaching body, and to these we shall probably refer at greater length next week. Sir James also proposed the toast of "Success to the Club," to which Dr. Leech responded. Sir W. Roberts proposed "The Sister Universities," to which Professor Ward replied; and Professor Greenwood gave "The Health of the Visitors," to which Mr. Lund and Mr. H. J. Roby responded.

DIARRHŒA FATALITY IN SHEFFIELD.

DR. SINCLAIR WHITE, in submitting to the Town Council of Sheffield a statistical report for the third quarter of the present year, takes the opportunity of referring in some detail to the question of infantile diarrhœa. The third quarter of the year is usually associated with the occurrence of this fatal infantile disease, and during the past quarter the effects have been, as described in the report, truly terrible. No fewer than 357 deaths have occurred from it, and of these 67 took place in one week. Of the 357 deaths, 330 were in children under five years of age. The seasonal influence in connexion with infantile diarrhœa is too obvious to need discussion; but, as Dr. White says, there is something more than season as a cause to consider, and he is convinced that the two additional causes which stand out most prominently are (1) improper feeding of infants, and (2) filth in its widest sense. The seasonal influence taken by itself does not cause epidemic diarrhœa, as has again and again been shown by contrasting neighbouring towns where heat and rain have been alike, but where the diarrhœa mortality has been altogether different; and, as is stated in the report, it is clear that this seasonal influence can only be dangerous where other favourable predisposing causes are present. Remove these and seasonal influence is practically inoperative for mischief. As regards the question of infant feeding, it is suggested that the Health Committee might with great advantage cause to be drawn up and printed for wide distribution simple hints which would be helpful to mothers and others. The filth difficulty is a greater one in a large borough, where the almost ubiquitous midden is in many places a serious nuisance. In the more crowded parts of the town these antiquated receptacles for filth, with their seething contents, are referred to as giving off offensive gases which pollute the air of the badly ventilated courts; and it is precisely such an influence as this that the sensitive organisation of childhood cannot withstand. From the remarks made in the report as to the small space about houses, it is quite evident that in many portions of the borough the ordinary midden-privy can only be properly replaced by some form of watercloset; and it is worthy of consideration whether some of the simple forms of this closet, which have recently been adapted to the needs of the poor and careless, might not, at least tentatively, be brought into operation in Sheffield. It is difficult to abolish a system to which people have been long accustomed, but there are now definitely recognised principles on which even midden-privies can be constructed with a minimum of risk to the people; and we fear that, although much has been done and is still doing in Sheffield, this subject has not yet been handled with determination. And, lastly, in addition to securing proper structures, with contents as dry as can be obtained, the authority should so arrange its scavenging department that no excreta and refuse should ever be left for many days in the vicinity of dwellings. A week should, in such a borough, be the outside limit at even the coldest times of the year, and a much more frequent removal of the filth causing such grave mortality should be insisted on during the diarrhœa season. We sincerely trust that Dr. Sinclair White's advice in these directions will be energetically followed, so that the amount of filth in Sheffield next autumn may be trivial compared with that which existed last year, and that in this way a prime cause of serious mortality may be effectually dealt with.

MR. FREDERIC HARRISON ON CITIES.

WE may not agree with Mr. Harrison on all questions, but it is impossible to dispute the intensity of his convictions. In spite of his fine pictures of ancient and mediæval cities, with their ample gardens and squares, their social life, and their State importance, we are disposed to be thankful that we live in modern London, with its comparatively pure water and pure air. But there is no need for too much complacency, and we may well lay to heart some of Mr. Harrison's criticism. We must, above all, have more room and open spaces. Not only must we jealously guard the spaces that yet remain in this monstrous conglomeration of towns which we call London, but we must create others, in which trees and flowers will grow for the revival of human spirits, and in which gymnasia may be established for the good of the young. The division of London into eight or ten separate counties, each with its own public libraries, public buildings, museums, baths, &c., may not be inconsistent with some common citizen life. The first condition and beginning of such a desideratum is the creation of intermediate spaces. And the time is favourable for this when ground is not so impracticably dear as it sometimes is.

MILK INFECTION: A SUGGESTION.

DR. JAMES F. ALLEN, medical officer to the Corporation of Pietermaritzburg, has written a very suggestive report on the causes of enteric fever in that city. Pietermaritzburg, he says, is in fair sanitary condition. It has a public water-supply, and the houses in which enteric fever made its appearance were not those in which any local condition of house construction could give rise to it. Last year this disease broke out round a small dairy on the outskirts of the town, the occupants of the farm entirely escaped, so far as he could ascertain. In this dairy specific enteritis among the calves had been very fatal; all the calves contracted the disease, and in each case it ended fatally, eight or nine dying altogether. The proprietor of the dairy states that the pasturage round his house is very unhealthy, and last year the calves were therefore kept tied up; nevertheless they did not escape the disease; but Dr. Allen notes that full-grown animals are exempt from it. As a rule, the calf disease made its appearance in this farm late in the summer, but last year the first calf must have died about the end of July or the beginning of August. Thirteen cases of enteric fever occurred altogether among persons resident in the neighbourhood—one in August opposite the affected dairy, the family of the sufferer receiving milk from this source. In another house five cases occurred among a household of seven. This household did not receive milk from the suspected dairy, but they used for fuel cowdung collected in the neighbourhood—not from

the affected calves, for these were tied up; but perhaps from other animals suffering from the same disease. In another family two cases occurred, and in this house cow-dung was also used for fuel, the source from which it came being unknown. Another case occurred in the person of an infant at its mother's breast, but this child, the mother states, received no other milk than her own. Concerning the household, no distinct mention is made of the fuel used for burning. The remaining four cases were all in one house; milk was not received by this household from the suspected dairy knowingly at the time of the appearance of the first case, but during this child's illness this dairy supplied the milk for the rest of the family, but it was at this time regularly boiled. Later, however, this precaution was neglected, and three other persons then contracted enteric fever. There is to be found in these cases nothing more than a suggestion that the bowel discharges from the animals in the dairy may have been concerned in the production of some of the cases of enteric fever in the neighbourhood. Dr. Allen has omitted to state the total number of households using for fuel the material which he suspects has given rise to disease, and the whole facts are therefore not sufficiently before us to enable any positive opinion to be formed on the subject; but Dr. Allen's story is well worth bearing in mind in any further investigation into the etiology of this disease. In another report Dr. Allen insists upon the simultaneous appearance of enteric fever among the inhabitants of the neighbourhood of farms and the appearance of what he describes as specific enteritis among the calves. He states that he examined the mesentery and small intestine of one of these animals; that he found the mesenteric glands enlarged, and in the intestinal mucous membrane evidence of the same diseased action as is to be found in that of human beings after death from enteric fever—thus ulceration and patches of inflammation involving Peyer's glands are to be found in both diseases; and he asserts that the two disorders in Pietermaritzburgh at least are always found together.

TRAPS FOR PUBLIC ANALYSTS.

MR. W. E. TAYLOR, town councillor of Bedford, has obtained an unenviable notoriety by his attempt to throw discredit on chemical analysis. With motives which doubtless seemed excellent to him, he arranged with a gentleman whom he describes as a "chemist of standing in his profession," to put poison into beer which was, under the provisions of the Sale of Food and Drugs Acts, forwarded to the public analyst for examination. The public analyst naturally did not seek for or find the poison, and as he chanced to be a man equally distinguished in chemistry and toxicology he can well afford to laugh at the device of the town councillor. But as the same trick may at any time be practised upon a young and unknown analyst, it is desirable, although to our readers unnecessary, to point out its absurdity. Our task is rendered easy by the crushing comments which Professor Corfield and Messrs. Bernard Dyer and Otto Hehner, the honorary secretaries of the Society of Public Analysts, have printed in *The Times*. Let Mr. Taylor and other town councillors who may wish to emulate his notoriety understand that the detection and exposure of fraudulent adulterations under specific Acts of Parliament necessitate a procedure diverse from that required for the detection of criminal poisoning. No doubt commercial adulteration is sometimes of a noxious kind, as when red lead has been added to cayenne pepper; but that is a very different thing from the addition by accident, or for merely criminal purposes, of a definite poison. We have been foremost in denouncing adulteration as a trade fraud in all cases, and as a grave offence against public health when a noxious substance has been used; but we distinguish entirely between the addition of water to milk—additions made only for a fraudulent purpose—and the addition, say, of arsenic to beer or aconitine to tea. No doubt a milk vendor may introduce a deadly dose of arsenic into every pint of milk that he sells and escape detection by the public analyst. But such an addition would not profit the vendor, and would be purely malicious—an offence against the common law. The dealer could have no commercial object in view, and the Acts are directed against commercial offences. If public analysts were compelled to search for all possible poisons in every sample of food or drugs submitted to them, the laws in regard to adulteration would soon become dead letters.

CALOMEL AS A DIURETIC.

THE virtues of calomel have in these days come to be somewhat undervalued—a reaction doubtless from the indiscriminate prescription of former times. Dr. Mendelsohn (*Deutsch. Med. Woch.*, No. 45) calls attention to its value as a diuretic, especially in cardiac dropsy, basing his remarks upon papers recently published by Dr. Jendrassik of Pesth and Dr. Stiller. The former, having noticed the marked diuresis which ensued in a severe case of cardiac dropsy after the administration of jalap and calomel, found by further observation of other cases that this effect was due to the calomel, and not to the jalap. In the great majority of the cases the daily quantity of urine reached from two to five or more litres on the second to fourth day of calomel treatment. Stiller's experience is confirmatory of this, and Dr. Mendelsohn adds his own testimony to the value of the prescription. He says that when calomel is prescribed in doses of from 0·2 to 0·3 gramme (i.e., 3 to 5 grains) three times a day, diuresis occurs within eight hours. It is not necessary to induce salivation to get this result, which often takes place with surprising rapidity; the anasarca and serous effusions disappear, and the patient is much relieved. It is said even to be more effective than digitalis, squills, and other remedies in certain cases, especially when the pulse-tension is not very low. Calomel does not, however, act through the heart, and is often advantageously combined with digitalis.

THE MURDER IN CORNWALL.

THOMAS POLGLASE, aged forty-eight, miner, was charged with feloniously, wilfully, and of malice aforethought, killing and murdering Charles Shearman, at Breage, Cornwall, on July 19th, 1886. He was tried on Saturday, Nov. 8th, before Baron Huddleston. The main facts of the case, as presented to the jury, were as follows. The prisoner left his house in the early morning to examine a rick, near which was some loose hay; he observed what he seems to have believed to have been a human being, with the body partly covered. No answer was given to a challenge made and repeated by the prisoner, whereupon he repaired to his cottage, seized a turf-axe, returned to the rick, and still getting no reply, he forthwith smashed in the skull of his unfortunate victim. Shortly afterwards he went to the police and stated what he had done. Dr. Adams, medical superintendent of the Cornwall County Lunatic Asylum, instructed by the Treasury, examined the prisoner with a view to testing his state of mind, and came to the conclusion that, though of weak intellect, he was not insane—taking mainly, as we suppose, delusions as the test of insanity. At the same time Dr. Adams was of opinion that the prisoner was beside himself at the time the tragedy occurred, or that whilst committing the act under the influence of terror he was not aware of the probable consequence. The judge ruled that the opinion of a medical man as to the prisoner's state of mind at the time when he had no means of examining him was inadmissible as evidence. In his summing up, his Lordship followed the rules sanctioned by the law. He told the jury that if they thought that the prisoner knew what

would be the result of the onslaught and that he was aware he was committing a wrongful act, he must be judged guilty of the crime of murder. The jury, whilst convicting the prisoner of the capital charge, unanimously recommended him to mercy. From a technical standpoint we have no desire to traverse the ruling of the judge. The law of England makes the knowledge of right and wrong the test of insanity. That it is utterly defective has been proved on more than one recent occasion. A man may know that he is committing a wrong act, but may be absolutely incapable of restraining himself. This is what is known as impulsive homicide. It seems to us that there was no actual premeditation or "malice aforethought" in the sense in which those terms are intended to be construed. From the time the prisoner discovered the deceased until the fatal blows were delivered his acts may be considered as one. He was evidently under the influence of over-awing fear that harm might come to himself, and prompted by the means of self preservation the deed was done. If the prisoner were of sound mind, it is obvious that the defence of excusable homicide could not be maintained, for there was no adequate incitement to kill. "Death by inadvertence or misadventure" is a theory wholly inapplicable to the case under consideration. We are unreservedly of opinion that the murder was committed under an irresistible impulse, and the condemned man must be held irresponsible for the act.

THE WORK OF THE COMBE TRUST IN SCOTLAND.

THE trustees of the late George Combe, as is generally, known, have for some years past carried on a highly beneficent work in various districts of Scotland, in the shape of the delivery of courses of lectures on Physiology and Health. These lectures were inaugurated seven years ago, at the suggestion of Dr. Andrew Wilson, of the Edinburgh Medical School, who was consulted by the trustees regarding the manner in which the wishes of Mr. Combe could best be carried out. Dr. Wilson has conducted these courses since their commencement in the principal centres of Scotland, other lecturers having from time to time been occasionally engaged in the delivery of lectures in the north and west, while Dr. Stirling has lately undertaken a course in Manchester. At Dundee, Perth, and other towns audiences ranging from 1000 to 1800 in number have attended Dr. Wilson's instruction. During the present year eight towns are on the list for Combe Lectures. Thus the pre-Christmas courses include Kirkcaldy, Penicuik, Carluke, and Airdrie. In the spring of 1887 Dr. Wilson visits Grangemouth, Coatbridge, Bonnyrigg, and Dumbarton. To the teachers of Edinburgh and Glasgow Dr. Wilson will deliver, in the summer of 1887, his third annual course of lectures, the subject being "Health as related to the School and the Home." It is needless to add any word of commendation by way of approval of this humane work of the Combe Trust. Lessons of health, taught clearly and forcibly to the masses, are calculated in the long run to work an immense amount of good.

GUY'S HOSPITAL.

THE following changes have recently taken place in the Guy's Hospital Medical School:—Dr. Goodhart, having been appointed full physician, retains his lectureship on Pathology, but resigns the posts of Curator of the Museum and Senior Demonstrator of Morbid Anatomy; these are filled by Dr. Carrington. Dr. Pitt has been appointed to the post of Junior Demonstrator of Morbid Anatomy. Dr. Taylor lectures on Medicine, together with Dr. Pye-Smith, thus filling the lectureship vacated by the death of Dr. Moxon. Dr. Hale White lectures on Materia Medica in place of Dr. Taylor.

VOMITING DURING PREGNANCY CURED BY ARTIFICIAL ALIMENTATION.

DR. BRUNNICHE, in the *Nordiskt Medicinskt Arkiv*, relates the case of a woman who was in the hospital for two months with cardialgic symptoms. She had pain, particularly in the left side of the epigastrium, which was diminished by pressure. She could retain no food, not even milk, and sometimes vomited blood. Urine normal; no fever; temperature 37°. She was treated for a time for gastric ulcer. No symptoms of pregnancy could be found by external examination. The patient became greatly emaciated, vomited everything, and was greatly reduced after sixteen days. Strong suspicions of pregnancy were now entertained, and Dr. Brünniche determined to try artificial alimentation. A sound was introduced into the upper part of the œsophagus and milk poured through it. Other nourishment was also administered in the same manner. An attempt to dispense with the sound brought on another attack of vomiting. Artificial alimentation was therefore continued for three weeks. At the end of this time the woman had entered on her fourth month; she began to take food, and entirely recovered. Dr. Brünniche remarks that he got the idea from the treatise of Dr. E. Bull.

POOR-LAW MEDICAL OFFICERS AND THEIR FEES.

MR. E. A. PIGGOTT, L.R.C.P. Edin., medical officer for the Second District of the Risbridge Union (Suffolk), has found it necessary to take proceedings in the Haverhill County Court against the guardians of this union for the recovery of a midwifery fee, due to him by virtue of an order granted by the relieving officer for his attendance upon a woman immediately after childbirth; the case being one of post-partum hæmorrhage entailing long subsequent attendance. Payment of the fee (£2) was refused, the reason for such refusal being the fact "that the guardians did not consider that their medical officer was entitled to a fee under the General Consolidated Orders of the Local Government Board." The case was to have been heard at the November sitting of the court, but a few days previously to the date of hearing the defendants thought it expedient to pay the amount claimed into court, thus admitting their liability and avoiding the expense of costs, &c.

SYPHILITIC INFECTION BY THE RAZOR.

PROFESSOR FLEISCHER recently reported to the Kieff Medical Society a case occurring in his practice where a man had contracted syphilis from an infected razor in one of the best hairdressing establishments in Kieff. The society thereupon decided to call the attention of the sanitary authority to the subject, in the hope that it would make regulations to obviate a repetition of such an occurrence. Another case of the same kind has also been published lately. It was that of a soldier, who had been infected with a primary sore of the chin from being shaved in a public shaving establishment in Tiflis. This case was shown to the Caucasian Medical Society by Dr. Chudnovski.

THE TREATMENT OF DIPHTHERIA.

THE heroic treatment of diphtheria has once more come to the front. Dr. Bloebaum of Coblentz advocates the employment of the galvano-cautery by means of an apparatus which is constructed by Messrs. Buehl, of 75, Coleman-street; and Dr. Nix of Rude, Denmark, recommends a still more radical method of scraping away the false membranes daily with a sharp spoon. Both authors adhere to the view that diphtheria is primarily a local disease. The object of the first-named is to destroy by fire the micrococci of diphtheria, which are regarded as its cause; and the aim of the Danish

physician is to extirpate the soil in which the cause of diphtheria is growing. We are glad to be informed of current attempts at improving the therapeutical art, and we wait patiently for the ultimate issue of such renewed attempts.

VAN HELMONT.

BRUSSELS is about to do honour to the University of Louvaine in the person of one of its most distinguished students of former times, Jean Baptiste Van Helmont, the celebrated doctor and chemist, to whom a statue is to be erected on the Nouveau Marché aux Grains. Van Helmont was born in Brussels in 1577, and at the age of seventeen had completed his studies of philosophy at Louvaine, and, it is said, appeared there as a public lecturer. He then set off on his travels and acquired a great knowledge of chemistry, to which he afterwards devoted himself. When in England he was presented at Court and invited to the brilliant entertainment given at Whitehall. He had already gained considerable reputation as a medical practitioner, and had introduced the use of sulphur, oil of vitriol, and other remedies. He was the first, in a work on the waters of Spa, to use the German word *geist* (ghost or spirit) to denote the air on which the properties of those waters depend whence the modern word gas. Amongst his many other discoveries was that of the gastric juice. Van Helmont died in 1644, at the age of sixty-seven, of asthma and pleurisy, shortly after he had published his famous work on Fever.

DEATH OF BISHOP McDOUGALL.

WE regret to record the death, which took place on the 16th inst. at Winchester, of Bishop McDougall, Archdeacon of the Isle of Wight and Canon of Winchester. The deceased was born in 1817 at Sydenham and educated at King's College, London, for the medical profession, where he obtained the gold medal in 1837. He became a Fellow of the Royal College of Surgeons of England, and for some time acted as Demonstrator of Anatomy at King's College. In 1845 he was ordained, went with Sir James Brooke to Borneo in 1846, and four years afterwards was consecrated Bishop of Labuan, The deceased returned to England in 1868, and was appointed by the Bishop of Ely to the vicarage of Godmanchester, a canonry of Ely, and the archdeaconry of Huntingdon; and at Bishop Harold Browne's translation he took him to Winchester, where alike in the diocese, ths chapter, and in Convocation his genial manners obtained for him high regard and esteem.

HONOURS TO THE MEDICAL PROFESSION.

ON the 16th inst. the Queen held an investiture at Windsor Castle. Amongst those who were introduced into the presence of the Sovereign were William Orange, M.D., and Arthur Mitchell, M.D., upon whose breasts Her Majesty affixed the decoration of the Civil Division of the Third Class of the Order of the Bath. Surgeon-General Michael Cudmore Furnell was afterwards introduced, and decorated with the Badge of a Companion of the Order of the Indian Empire.

NEW OPERATION FOR PROLAPSUS UTERI.

A MEXICAN medical journal gives an account of an operation practised by Dr. Malanco for the purpose of forming a kind of false uterine ligament in cases of prolapsus. It consists in passing a trocar from the anterior vaginal fornix to the abdominal wall (taking care, of course, to avoid the bladder), and in applying the actual cautery to the track by means of a thermo-cautery inserted through the cannula from the front. The proceeding, which was first proposed by Dr. Fenelon, of Mexico, is stated to have been employed several times with the most successful results.

THE DECLARATION OF THE POLL.

THOUGH one day is considered enough to count the votes, there is reason to fear that the profession may have to wait till the 20th for the declaration of the poll. This delay will be most unsatisfactory, and will be attributed by the profession, and justly, to the shocking waste of time by the Medical Council in its present fruitless sittings, which threaten to extend into next week.

"DESCRIBED AS A MEDICAL MAN."

IT is surely due to the honourable profession of medicine that officials of our police and other courts, and those responsible for reports in newspapers, should take steps to ascertain whether a prisoner "described as a medical man" has any legitimate claim to that title. A recent shocking case, in which a prisoner has just been sentenced to hard labour for twelve calendar months, is published as an "extraordinary assault by a medical man." The name of the prisoner in question does not appear in the Medical Register or in the Medical Directory; he is, we believe correctly, described in *The Times* as a "medical rubber." The honour of our profession, exposed as it is to the risk of false charges, cannot be too jealously guarded.

TESTING THE RABIDITY OF DOGS.

MR. VICTOR HORSLEY writes to say that Dr. Hime was not the first in this country to test the rabidity of a dog (that had bitten an individual) by Pasteur's method. On June 1st Mr. Horsley made an examination of a dead dog sent by Dr. Peart of North Shields to the Brown Institution. The dog had bitten a young lady. Mr. Horsley proved by the post-mortem appearances and inoculations of rabbits that the dog did not die of rabies. The young lady, though advised to go to Paris, declined to do so, and her refusal was scientifically justified, for the rabbits inoculated with the dog's medulla did not die.

STEPS are at length being taken at Cambridge University to provide Professor Michael Foster with additional accommodation for the teaching of physiology. Dr. Foster found himself confronted this term with a class of nearly 100, who were to receive practical instruction in a room capable of containing about 80. He accordingly laid before the University the alternative of diminishing his class by about half or providing fresh room. Naturally the latter alternative was adopted, and the Museum Syndicate have recommended the erection of a large lecture room on the east side of the Museum of Comparative Anatomy, at a cost of about £450.

OUR Belfast correspondent writes:—"Considerable discussion is taking place here in the papers and in private circles in reference to the vacant seat in the Royal University; indeed, it is exciting more interest than the election to the Medical Council of a representative. Many think that the fairest course is that which was taken by the Presbyterian Graduates' Association, who passed a resolution 'That, recognising the claims of the southern graduates and Cork College to a fair representation on the Senate of the Royal University, we do not see our way to nominate a candidate in opposition to the candidature of Professor O'Sullivan, M.D.'"

As the retirement from the Service of Brigade Surgeon James Keess, M.D., L.R.C.P.I., the Principal of the Medical College and senior medical officer to the General Hospital, Madras, is fast approaching, his numerous friends and past and present pupils have decided to perpetuate his name by founding a scholarship in connexion with the Madras University, of which he is a Fellow.

THE latest reports from Jamaica state that the outbreak of small-pox at Kingston is increasing. The total number of cases under treatment since the commencement of the epidemic was at the time of the departure of the mail 422, and there had been over forty deaths. Kingston is reported to be in a very insanitary state, and the authorities seem totally unable to carry out the duties imposed on them. The epidemic in Colon is decreasing rapidly.

THE fortieth and concluding volume of the Dictionary of Practical Medicine and Surgery, which has been brought out by Dr. Jaccoud, Professor of Clinical Medicine in the Faculty of Medicine of Paris, has just appeared. The complete work, the production of which has occupied many years, contains 33,000 pages and 3600 illustrations.

AT a meeting of the Society of Medical Officers of Health this (Friday) evening, Mr. Mark Judge will make a communication on the subject of the Sanitary Registration of Buildings Bill for the purpose of discussion by the Society. The Bill is to be brought before Parliament during next session by Dr. R. Farquharson, M.P.

IN the High Court of Justice, Chancery Division, on the 13th inst., Mr. Justice North made an order giving the sanction of the Court to the alteration of an existing scheme by the enlargement of the number of, and the change in the mode of electing, curators of the Botanical Gardens and Museum at Oxford.

JOHN SYER BRISTOWE, M.D., F.R.C.P., F.R.S., has been re-elected Physician to St. Thomas's Hospital for a further period of five years. Joseph Frank Payne, M.D.Oxon., F.R.C.P., has been appointed additional Physician; and Mr. George Henry Makins, F.R.C.S. Eng., an Assistant-Surgeon.

THE Queen, with the advice of the Privy Council, has been pleased to renew for a further period of five years from the 29th inst. the appointment of Mr. Robert Dyers Lyons, M.B., as a member of the General Council of Medical Education and Registration for Ireland.

DRS. PEKELHARING and Winkler, of Utrecht University, have been commissioned by the Colonial Minister of Holland to proceed to the East Indies for the purpose of investigating the causes of Beri-beri.

THE cholera epidemic at Flinthen and Gonsenheim has come to an end. The limitation of the disease is attributed to the prompt and thorough manner in which sanitary measures were enforced.

THE *Birmingham Medical Review* continues to publish excellent articles on the Histology of Scarlatina by Dr. Crooke, and on the Spectroscope in its Biological applications by Dr. MacMunn.

MR. SHIRLEY MURPHY has been appointed Lecturer on Hygiene and Public Health at St. Mary's Hospital Medical School.

THE HOSPITALS ASSOCIATION.—On the 17th inst. a *conversazione* was held at the rooms of the Medical Society of London, for which invitations had been issued by the Hospitals Association to the presidents, chairmen, officers, and supporters of the metropolitan and provincial hospitals and asylums. Addresses were delivered by Sir Andrew Clark and Sir Sydney Waterlow.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THE General Medical Council assembled on Tuesday the 16th, Sir Henry Acland, President, in the chair.

DR. WM. MITCHELL BANKS, introduced by Sir D. Duckworth, took his seat for the first time as representative under the Medical Act, 1886, of the Victoria University, Manchester.

The PRESIDENT then delivered the following address:—

There appears to be no sound reason for questioning the opinion held by many members of the Council that a short autumnal meeting is necessary for the due discharge of its duties. This year forms no exception. The Register should always be corrected as late as possible for the printed issue in January, and questions affecting the removal of names from the Register should therefore, as a rule, be decided before the end of the year. It may also happen—as this year it does happen—that reports of committees may be advanced a stage, and work be prepared for further consideration at the longer meeting in the spring of the ensuing year. The remarks that it is my duty to make at this meeting will be very brief, because chiefly repeating an oft-told tale. Although much debatable matter will be laid before the Council, its deliberations thereupon may, if it so seem fit, be for the present brief also. The following subjects require your attention:—1st, Criminal Cases; 2nd, University Examinations; 3rd, Visitation of Teaching at Schools; 4th, The Pharmacopœia; 5th, Registration of Sanitary Diplomas; 6th, Combination of Examining Bodies; 7th, some particulars of the Medical Act, 1886.

1. Only two cases of a criminal character require your attention. One is the removal of the name of Mr. Alabone from the Register, he having been deprived of his membership by order of the Royal College of Surgeons of England. The second case is one of a class which has been often before you, and has already received careful and serious attention from the Council. The permanent Under-Secretary of State for the Home Department forwards from the Deputy Coroner of Westminster a letter and depositions taken at an inquest on a person who had been attended by the unqualified assistant of Mr. Day. Mr. Lushington gives no opinion on the case, but the coroner expresses to Mr. Lushington his conviction that the Council should prosecute Davenport; while the Registrar-General, to whom Mr. Lushington referred the case, states that Mr. Day was within his legal rights in respect of signing a death certificate for the deceased. The solicitor to the Council has had all the papers bearing on this difficult matter referred to him, and is fully prepared at your desire to give his opinion on the whole subject. In cases of misconduct of this description, the Council may express strong disapproval of the action of a registered practitioner. The only punishment, however, it can inflict is the erasure of the name from the Register, and this on previous occasions the Council has not thought fit to inflict, although it has pointed out in strong terms the wrong and the danger of the system, and the probable necessity of legislation upon the subject. As regards the unqualified assistant himself, the Council has no direct power under the Act. It can recommend the case to the consideration of the public prosecutor. All these circumstances are fully and clearly set forth in the report on the subject to be found in the twentieth volume of the minutes, together with the resolutions then arrived at by the Council. The powers of the Council in these cases were again brought before the Council in my address last year, after the fullest consideration with your solicitor. In the then state of public business legislation on this matter was impossible. Whether the Council will take the present opportunity of urging the Government to deal with the matter through the Home Office or otherwise will rest with the wisdom of the Council.

2. I will refer but very briefly to some other topics which demand immediate consideration. A further report of the Statistical Committee will be presented to you. It carries its interesting and elaborate investigations still further into the movements in life of those who enter the medical profession. The report will not, it is to be presumed, give rise to detailed discussion during the present session. The next report to be submitted to you is pregnant of more immediate

results. Mr. Marshall's Committee on the Visitation of the Universities has prepared a document which, I will venture to say, is second in importance to none produced since the Professional Examination Report by Mr. Syme's Committee in 1869. It sets forth, by a careful and judicial analysis, some of the conclusions to be drawn from the reports on the Visitation of the Universities, and from the remarks of the universities thereupon. There is no detail of the higher examination system in medicine which it does not, directly or indirectly, touch. This report, and that by Mr. Teale, Professor Gairdner, and Sir William Stokes, taken together, give a clear insight into the merits, failings, and limits of variation of all the licensing bodies in Great Britain and Ireland. Whether the Council now take up this subject fully or not, I have reason to think that Mr. Marshall may draw your special attention to the conclusions at which the reporters have unanimously arrived. It is hardly possible that these conclusions can be adopted without considerable discussion. If, however, the conclusions be ultimately accepted, it may happen that the elaborate and reiterated visitation of examinations can have some respite. This will depend on the instructions given to future inspectors. It is not easy to see how the instructions can be more comprehensive than they have hitherto been. But the general method of visitation or inspection may be modified in various ways. It will be proposed to refer the whole subject to a committee. Now that every qualifying examination by every licensing body is to be complete in every part, the Council will have, no doubt, to see that this is virtually true in the case of any and every body that hitherto has only given a partial examination. At all events, after June 1st, 1887, no examination can be deemed to be qualifying or registrable concerning which the Council is not satisfied upon this cardinal point. It is a great relief to the Council that this vexed question, which Lord Ripon strove to settle sixteen years ago, and on which successive Governments have been repeatedly thwarted, is at length set at rest. It would be an error, however, to suppose that no difficulties and no pitfalls remain, before the actual working is fully established throughout the twenty separate or combined licensing bodies.

3. But if the examiners have thus some repose, the same fortune may not befall the teachers. The next report you will receive is in an incomplete state. It is one on the Visitation of Teaching; on its methods and its appliances. Time was when men seemed to take a melancholy, or, to speak more truly, a cheerful view of high percentages of rejections. A more instructive idea of the use of visitation is now occupying the minds of many men. They ask, Why do so many fail? And they desire to know, not so much what they are examined in as what they are taught; and not only what they are taught, but how, and with what appliances. It is not, however, to be supposed that this view has been neglected. Still, all persons who are interested in the progress of education will look with extreme interest on a full account of the appliances and methods of teaching the sciences at the foundation of medicine, and the means of acquiring knowledge in the practice of its several parts, as they prevail in the medical teaching institutions in the kingdom. These are known to vary much in their scope, as well as in their power and opportunities. It is possible that the less thoughtful portion of the public may wonder that labour should be expended at the end of the nineteenth century on a matter which would be supposed to be already well understood. No member of this Council, however, but feels the difficulty of blending into practical medical education the sciences, whose mass increases daily, and each of whose votaries has a tendency to claim the attention of students, if not exclusively, yet absorbingly, to the special work of his own life. You will be asked to receive the Committee's report on this matter, and to give further instruction with regard to it.

4. A report on the Pharmacopœia will also be presented to you, with important suggestions for its future management and progress. No part of the duties of the Council demands more philosophic attention than the transitional state of knowledge in regard to remedial agents and the science of pharmacy. A request having been made to me to deliver an address to the Pharmaceutical Society, it seemed to me a duty, considering the work done by that important body for the Pharmacopœia, to comply with their wish. A copy of this brief address has been forwarded to every member of the Council.

5. I can hardly conclude without some allusion to the short Act which passed in the last session of Parliament, giving certain additional powers to the Council, and adding eight to its numbers. The most important change in relation to education wrought by the Medical Act of 1886 with respect to the duties and powers of the Council is the giving to it the power and duty to which I have just referred—viz., to require that every person admitted to the Register should have passed an examination qualifying in every subject. The Act also enables certain qualifications in sanitary science to be entered in the register. On this a motion will be submitted to you by the Chairman of Business. I may here observe that several years ago an attempt was made by Dr. Storrar and myself to effect a combination between the Universities of Oxford, Cambridge and London for conferring a well-considered national diploma in Preventive Medicine before any such diplomas had been given by any in England. I grieve to say that this attempt failed, and the evil of a number of certificates given by various bodies without any agreement or combination is already rife in a wholly new subject. The same distinguished examiners examined lately one candidate at Oxford and two in London, at great cost and much labour and many appliances, in two consecutive weeks, and voluntary associations also are conferring the same titles. Cannot this misfortune be still remedied before it is too late, by some combination of the proper authorities for the purpose?

6. Communications from Ireland with respect to the combinations of the several corporations in Dublin for the purpose of forming one examining Board will be laid before you. The question of the power and rights given by the Act of 1886 in respect of combinations necessarily comes at once before the whole Council and need not be further considered now. It will recall to the minds of some the thought of the divisional boards of the Royal Commission in the Medical Act, and the protracted discussions on voluntary conjoint boards. If it were now fully discussed it might be necessary to discuss also some of the changes actually made or proposed to be made in London both as to combinations and to degrees.

7. These several powers, conferred under the Acts of 1886, have, I need hardly say, been long desired by the Council. But the nature of Parliamentary Government made any serious change in our educational procedure impossible, without at the same time a change in the executive that was to carry it out. Modifications in the examination system, once held to be of the first importance, and therefore of greater consequence than a change in the executive, are left untouched by the Acts of 1886. The licensing bodies all retain their respective and separate powers. I hope to revert to the significance of this result of sixteen years' delay on another occasion. The addition to the executive being now made, it is to be hoped that the Council may be able to pursue the even tenour of its way, with whatever force it may acquire by addition to its numbers. But into this subject also it would be premature to enter, till we reassemble in the early part of next year.

There remains but one more subject to be noticed as to our order of business. By the Medical Act of 1886 the members of the existing Council remain in it unaltered. An addition of five is made by general election in England, Scotland, and Ireland, of two by the Scotch Universities, and of one by the Victoria University, making the Council thirty-two in number. I am sorry to say it will hereafter lose one Crown nominee, and the president is to be a member of the Council. The number, therefore, will be thirty. The existing president was made by the Act the returning officer to carry out the election, unless you decided otherwise. Having to the best of my ability discharged this office, it will be, also by the Act, my duty and my privilege to summon the enlarged Council early in next year.

You will have noticed that I have now expressed no opinion as to the effect on the work of the Council of increasing the numbers of this deliberative and executive body. We have for twenty-eight years striven to do work which, as years have gone on, has in the nature of the case been much varied and has greatly increased. Its general character remains unaltered. I feel confident that the work will be undertaken with equal earnestness by those who will shortly be chosen to enlarge the body.

There are several other matters besides those which I have mentioned, some connected with the recent Act, which might be now referred to. But, as they do not at present press, I will not detain you longer from the work which lies immediately before us. Of this I will only say that a co-operation

in the history of medical education has there been more need for that which the Council will certainly give, careful and impartial judgment—all the more careful and deliberate because the long-expected legislation has left every medical institution free to act its independent part for a great public end, subject, as heretofore, to our common consultative recommendation and supervision, and with the support and assistance of the Privy Council.

On the motion of Mr. MARSHALL, seconded by Sir. W. GULL, the address was ordered to be entered upon the Minutes.

Mr. Marshall, Dr. A. Smith, and Dr. Struthers were appointed to form the Business Committee.

The Army and Navy returns were received, and a vote of thanks passed to the Directors-General.

The following communication was read from the Royal College of Surgeons of England:—

Royal College of Surgeons of England, Lincoln's-inn-Fields, W.C.
October 21st, 1886.

SIR,—In pursuance of the provisions of Section 28 of the Medical Act of 1858, I am desired to forward to you, for the information of the General Medical Council, a copy of the following resolution, which was adopted by the Council of this College on August 5th last, and confirmed on the 14th inst.—viz.: "That Mr. Edwin William Alabone, admitted a member of the College on May 17th, 1870, has, in the opinion of the Council, advertised or published matters prejudicial to the interest and derogatory to the honour of the College, and disgraceful to the profession of Surgery, and has further been guilty of a breach of the declaration made by him on his admission as a member, whereby he undertook to demean himself honourably in the practice of his profession, and to the utmost of his power to maintain the dignity and welfare of the College, and that he accordingly be removed from being a member of the College." I am Sir, your obedient servant,

EDWARD TRIMMER, Secretary.

On the motion of Mr. MARSHALL, seconded by Dr. QUAIN, the Registrar was directed to remove from the Register the qualification of M.R.C.S. of England formerly held by Mr. Edwin William Alabone.

A subsequent resolution directed the Registrar to remove Mr. Alabone's name from the Register, and in reply to a letter from him requesting to have his name erased, it was decided to inform him that in consequence of a communication from the Royal College of Surgeons it had been done.

The report of the Pharmacopœia Committee was received.

The next subject considered was a certain addition to the standing orders suggested by the Executive Committee, and submitted to the General Council, pursuant to the following resolution passed by the Council on June 2nd—"That Mr. Muir Mackenzie's opinion (in regard to the removal of qualifications from the Medical Register on the withdrawal of such qualifications by the licensing bodies) be referred to the Executive Committee with a view to their proposing to the Council such form of standing orders as they may think desirable to provide for the procedure of the Council when dealing with questions of the kind."

Mr. MARSHALL moved that the standing orders suggested by the Executive Committee be standing orders of the Council:—"(*a*) When the General Council has received notice from a licensing body that any qualification or qualifications have been duly and legally withdrawn from a registered medical practitioner by such body, then the Councill shall, if it thinks fit, by formal resolution proposed from the chair, direct the Registrar to remove such qualification or qualifications from the Medical Register. (*b*) If, under the direction of the General Council, all the qualifications of any registered medical practitioner have been erased from the Medical Register, then the Registrar shall, without further direction from the Council, forthwith erase the name of such practitioner from the Register." He said the first standing order simplified the procedure of the Council only in this particular, that whereas he had that day moved a specific resolution for the removal of Mr. Alabone's qualification from the Register for the future, that motion would proceed at once from the chair. The second standing order would do away with the resolution, such as that which he had just proposed, that the name of the person be struck off the Register. The point about which the Council had to be careful was the removal of the qualification. The removal of the name, the qualification being gone, was a mere technical proceeding, and might be safely left in the hands of the Registrar to save the Council the necessity of proposing a second resolution. The proposed standing orders were not very grave or serious, but, at the same time, they simplified the proceedings in those delicate questions which constantly gave rise to discussion. Mr. Simon had suggested that they had better introduce in the first standing order a reference to the point in the Act which said that no man should be removed in consequence of adopting any particular theory, and that therefore it would be safer to introduce after the words "by such body" the words "and that such withdrawal was not on the ground of his having adopted any theory of medicine or surgery."

Mr. SIMON seconded the adoption of the first standing order as amended.

Dr. MATTHEWS DUNCAN did not like the words "if it thinks fit." He could not see that the standing order as it stood would facilitate the progress of business in the slightest degree.

Mr. MARSHALL said if it did not simplify the procedure, it directed what it should be. Previously they had had discussions, not only as to the merits of cases, but also as to how they should be dealt with, and by simplifying the procedure the standing order would facilitate their business.

Mr. FARRER (the solicitor to the Council) thought the first standing order would help the Council in the conduct of its business, because it would be a motion, of course, from the chair. The words "if it thinks fit" were put in in order to prevent it being even suggested that the Council had no power of dealing with this as it pleased, and they also appeared in the Act of Parliament. With regard to the second standing order, he must confess that he was very chary about removing a man's name from the Register without the express direction of the Council.

The motion for the adoption of the first standing order as amended was agreed to.

Mr. FARRER suggested, with regard to the second standing order, that it should follow the wording of the first and read: "If, under the direction of the General Medical Council, all the qualifications of any registered medical practitioner have been erased from the Medical Register, then the Council shall, if it thinks fit, by formal resolution proposed from the chair, direct the Registrar to remove the name of such practitioner from the Register."

Mr. MACNAMARA thought that a far better plan. It had been contended on more than one occasion that the Council had authority to retain a name on the Register when the qualification had been removed. The plan suggested by their legal adviser would leave their hands more or less untied, and would be far safer for them.

The standing order was then agreed to as proposed by Mr. Farrer.

Additions to the standing orders in similar words were also agreed to with reference to the removal of qualifications or names from the Dentists' Register.

The Registrar next read communications from the Secretary of State for the Home Department with respect to the evidence given at an inquest before the Deputy Coroner of Westminster on the body of a man named George Wadley. The coroner had drawn the attention of the Secretary of State to the conduct of Mr. Day and Mr. Davenport, the latter being an unqualified assistant to the former. The evidence given at the inquest was to the effect that Mr. Day visited the deceased on Sept. 27th last, and afterwards signed a certificate of death, Mr. Davenport having attended on other occasions.

Mr. SIMON moved that the recommendation of the Executive Committee be adopted, and "that it be an instruction to the committee to bring under the notice of the Home Secretary the resolutions passed by the Council in its session in 1883, on the subject of the employment of unqualified assistants, and especially the first of those resolutions." Three years ago the Council asked for "legislation to the effect that any registered practitioner practising for gain who knowingly and wilfully deputes a person not registered or qualified to be registered under the Medical Act, to professionally treat on his behalf, in any matter requiring professional discretion or skill, any sick or injured person, shall be subject to the same legal liabilities as a person who falsely represents himself to be a legally qualified medical practitioner, but with special proviso that such enactment shall not hinder any duly regulated training of pupils by qualified teachers, nor any legitimate action of nurses, midwives, or dispensers."

Mr. MARSHALL seconded the motion.

Dr. DUNCAN said that the subject of unqualified assistants was beset with difficulties. It would be a very great cruelty to the poor to be very strict about unqualified assistants.

Dr. CHAMBERS considered that the case referred to by the Home Secretary was a very bad one. The registered practitioner lived miles away, and employed an unqualified assistant to do his work.

Dr. QUAIN said that the duty of the Medical Council was to superintend medical education, and registration, and not to act as criminal prosecutors. It was for the Home Secretary himself to take action in such cases.

Mr. MACNAMARA thought that the recommendations of the Council could not apply to Mr. Davenport. The persons to blame were those who employed unqualified assistants.

Mr. MARSHALL approved of the resolution, its object being, irrespective of any particular case, to get the Home Secretary to take action with regard to such matters.

The resolution was agreed to.

On the motion of Mr. SIMON, seconded by Sir WM. GULL, it was then resolved: "That the question of Mr. Day's professional conduct be referred for consideration to the English Branch Council."

Mr. MARSHALL brought up the third report from the Statistical Committee, which, as appeared from the opening statement, completed that part of the design of the Committee, which was to endeavour, by following the paths of the registered students of a certain number of years, to show whence and how the several ranks of the medical profession were recruited. The present report exhibited the results of a research comprising five years, and also included a comparison between the first and last years of the quinquennium. The investigation had included the tracing of the destinies of 6403 registered students, 4172 of whom were found to have gained a place in the Medical Register, and furnished on the most reliable data obtainable an analysis and record of facts such as nowhere else existed. The heaviest part of the Committee's undertaking was now accomplished, and it was hoped that in future a quinquennial analysis of a similar kind would be made and published. The investigation now completed served to illustrate the mode in which the medical profession was, as it were, built up piece by piece by the action of the individual units continuously added to it, but it was obviously desirable to endeavour to obtain a picture of it as it existed at particular intervals of time. It was proposed therefore to construct, so far as this could be done, what might be termed a census of the profession at two selected annual periods, and the years chosen for the purpose were 1881 and 1886. The former year constituted a suitable period to begin with, because it coincided with the date of the periodic censuses of the whole population of the United Kingdom, with which it would be most desirable to institute comparisons of various kinds, while the latter year, 1886, would serve to divide equally the decennial interval, and, moreover, it fortunately coincided with the date of the election of the direct representatives of the profession on the Council, which would again recur after another interval of five years. Such quinquennial censuses would clear up many most interesting points, such as the strength of the profession, its distribution, its fluctuations, migrations, and many other details relating to titles, qualifications, age, mortality, and so forth. In conclusion, he moved that the report should be received and entered on the Minutes.

Dr. A. SMITH seconded the motion.

Mr. SIMON, in supporting the proposition for a quinquennial census, suggested that once in every five years a circular should be sent to every member of the profession inquiring whether he had ceased to practise. No doubt there would be many who would fail to reply, and their names, according to the directions of the Act, would be left out of the Register for the year. The result would no doubt be a batch of letters correcting the Register to the last minute, and so they would get the maximum correctness possible.

Mr. MARSHALL said he was very glad to find that the efforts of the Statistical Committee were bearing fruit in this direction, that they would enable the Council to correct a charge which had been thrown in their faces over and over again as to the incorrectness of the Register. The Register was not so incorrect as some asserted, but of course it was not correct. He was very glad that the labours of the Statistical Committee would be reflected, as it were, into the path of making the Register as correct as possible.

Dr. DUNCAN entirely sympathised with Mr. Simon and Mr. Marshall, but he had a very strong impression that the subject required to be much more carefully considered. He thought the plan proposed, of a quinquennial correction, would lead to a great deal more inaccuracy than ever. The inaccuracies in the Register consisted mainly of change of address, and the result would be that in hundreds of cases, according to the statute, the letter not being answered within six months, the name would be erased from the Register. It would be better to let the Register alone, and leave it to the practitioners to correct it. If there were this quinquennial letter they would land themselves in a more incorrect Register than ever.

Mr. TEALE supported Dr. Duncan's view, and read a letter from a practitioner who complained that he had twice been struck off the Register without notice, although residing in the same place for the last twenty-four years.

The REGISTRAR said that cases of the kind did sometimes occur, and had been the subject of much correspondence. In one case which was laid before the Executive Committee the complainant at last came into the office, and said he found he had thrown the letter into the waste-basket, and no doubt the same thing had occurred in the case of Mr. Teale's correspondent. The letters were certainly posted to him.

The resolution for the reception of the report was then agreed to, and the Council adjourned.

On Wednesday, the 17th inst., Dr. Heron Watson proposed a resolution respecting the qualifications of candidates for commissions in the medical staff of the army and navy, which was seconded by Sir Dyce Duckworth, and agreed to. The report of the Pharmacopœia Committee was then presented and received. Mr. Marshall moved that the provisions of the Medical Act, 1886, concerning the registration of diplomas or certificates in sanitary science be forthwith carried out. Mr. Simon seconded the motion, and Dr. Quain, Dr. A. Smith, Mr. Macnamara, Sir Dyce Duckworth, Dr. Banks, and Mr. Teale took part in the discussion. The resolution was eventually agreed to. A motion proposed by Dr. McVail, respecting the duration of professional study, was, after long discussion and some modification, agreed to by 10 votes to 3, and the proceedings terminated.

At the meeting of the Council on Thursday, the case of a registered dental practitioner, Thomas Maden, was considered, the registration of whose name, according to the statement of the Dental Committee, had been incorrectly and fraudulently obtained. The Solicitor to the Council stated that upon the report of the facts by the Committee the Council had power to erase the name from the Register, and this was accordingly done. A discussion then took place on a motion by Dr. Banks, "That, subject to legal opinion, the title of 'holder of diploma in Public Health' be adopted as the heading in the Medical Register under which all practitioners duly certified in Sanitary Science may be placed, the sources of their titles being designated in each case." It was urged in favour of the motion that the holders of such diplomas were very desirous to have them registered under a uniform title; but it was contended by Dr. Humphry, Sir William Gull, and other members, that the Council had no right to enter the titles under any other designations than those given by the bodies conferring them. Ultimately, Dr. Banks withdrew his motion, the whole matter being left to the Executive Committee. Mr. Marshall then brought up a provisional report from the Visitation of Examinations Committee, embodying certain conclusions to be brought under the notice of the Council; but after some discussion th consideration of the subject was deferred. Dr. Heron Watson brought up a report from the Visitation of Schools Committee, which was ordered to be received and entered on the Minutes. The discussion on the subject of the adoption of the report was adjourned.

A full report of Wednesday and Thursday's proceedings will appear in our next issue.

THE LATE DR. BULL.—A tribute to the memory of the late Dr. Bull, physician to the Hereford Infirmary, and the author of the "Herefordshire Pomona," has recently been placed in the Hereford Cathedral. It consists of a marble tablet, and is affixed to the wall of the south-east transept. The inscription, surmounted by a gilt Maltese cross, is inlaid on white polished alabaster, in plain bold lettering, and is surrounded by a moulded and polished green marble border. The tablet has been obtained by general subscription, and the inscription refers to Dr. Bull's unwearied efforts for the relief of human suffering, to his perseverance in the pursuit and illustration of natural science, and to his zeal in all works of Christian charity and social improvement.

THE APOTHECARIES' SOCIETY AND THE CONJOINT BOARD.

ON Tuesday last a meeting was held at the Apothecaries' Hall to consider the subject of the amalgamation of the Examining Board of the Apothecaries' Society with that of other medical institutions having the power of granting diplomas in accordance with the Act of 1886. The meeting was summoned at very short notice, and consisted of members and licentiates of the Society and of other gentlemen interested in the question of medical education. The proceedings were opened by Mr. W. Shillito, who occupied the chair and who gave an account of the action taken by the Society in compliance with the requirements of the Act of the present year. In July the Society addressed to the Presidents of the Colleges of Physicians and Surgeons a letter proposing that the Society should join these Colleges in the formation of one examining board, but, beyond the acknowledgment of the receipt of this letter, no communication was received till an hour before the meeting.

The following is a copy of the correspondence :--

Society of Apothecaries, Blackfriars, E.C., July 21st, 1886.

To the President of the Royal College of Surgeons, and to the President of the Royal College of Physicians.

SIR,—The Medical Act of 1886 gives an opportunity for me, on behalf of the Society of Apothecaries of London, to address the following communication to you. In making it the Society are perfectly aware of difficulties which may be suggested, but they believe that these difficulties are capable of being removed, and that the Royal Colleges as well as the Society would greatly benefit by their removal. It is unnecessary to do more than refer briefly to the fact that a few years ago a combination was practically arranged under the provisions of the Medical Act, 1858, between the Colleges and the Society, and it will be admitted that its abandonment (from whatever cause) was not due to any action on the part of the Society. In the autumn of 1884 the Colleges formed under the Act of 1858 the combination under which they are now conducting a conjoint examination. Such a combination neither could or did prevent competition. It neither could nor did profess to give an exclusive or special right of being placed on the Medical Register, and in fact it only produced a result (at increased cost) which it was possible to attain by other means. But under the Medical Act of 1886 the Colleges will have to encounter a competition of a still more formidable character. Assume, for instance, that the Society is unable to combine, it will be in a position to ask for the appointment of assistant examiners. With that assistance it will be able alone to grant a statutory diploma in Medicine, Surgery, and Midwifery, and the result will be that within the distance of less than a mile two distinct authorities will, upon different terms, be granting the same statutory diploma. Such a competition should, in the interests of the public, be, if possible, avoided. Nor should it be forgotten that if the Colleges be unwilling to combine with the Society there is still open and possible to the latter a very formidable combination, which, in this alternative, would equally cause a very serious competition to arise to the prejudice of the Colleges. The Society are not shutting their eyes to the difficulty arising from the fact of the Royal Colleges being already in combination, but they insist that the advantages which would accrue to the Colleges and to the public by excluding unnecessary competition are such as ought to outweigh and overcome any such difficulty; in fact, that it is perfectly possible for the existing combination between the Colleges to be modified so as to bring the Society into it. Until the principle of combination with the Society is favourably accepted, it is premature to go into details; but it may be assumed that the Society will not ask for any terms which are not reasonable, and will give every facility on their part.

The Society would therefore urge on the Royal Colleges their careful and serious consideration of what has been placed before them.

I have the honour to be, your most obedient servant,

(Signed) EDWARD FURLEY, F.R.C.S., Master.

November 15th, 1886.

SIR,—We have the honour to inform you that your letter of the 21st of July last addressed to the President of the Royal College of Physicians of London, and also to the President of the Royal College of Surgeons of England, was submitted by them to the governing bodies of the two Colleges, and we are directed by the governing bodies of the two Colleges to inform you that the following resolution has been adopted by them:—"Inasmuch as the examination, conducted by the Examining Board in England, constituted by the Royal College of Physicians of London and the Royal College of Surgeons of England, is a complete qualifying examination in Medicine, Surgery, and Midwifery, conferring the right of registration under the Medical Act, a combination of the two Colleges with the Society of Apothecaries is for examination purposes unnecessary, and in the unanimous opinion of the Committee is also undesirable."

We have the honour to be, Sir, your obedient servants,

HENRY A. PITMAN,
Registrar of the Royal College of Physicians.
EDWARD TRIMMER,
Secretary of the Royal College of Surgeons.

To the Master of the Society of Apothecaries of London.

Mr. GEORGE BROWN (secretary of the Medical Defence Association) opened the discussion by asking whether the Society had determined upon the course it would follow.

Mr. WICKHAM BARNES, secretary to the Association of Poor-Law Medical Officers, then rose to propose a resolution, which he said he felt it his duty to put before the meeting, a duty which, as a Fellow of the College of Surgeons, was painful to him for the reason that the resolution expressed disapproval of the course which the Colleges had determined to adopt. The resolution was as follows:—"That this meeting, having heard the letter addressed by the Society of Apothecaries of London to the Presidents of the two Royal Colleges, and the reply thereto, signed by the registrars of the two Colleges on their behalf, regret to hear that such reply is so unsatisfactory, and to find that the Colleges have not duly considered the interests of the public in this matter."

Mr. STEELE, secretary of the Society of Members of the Royal College of Surgeons, seconded the resolution, and reminded the meeting that at a recent annual meeting of the Royal College of Surgeons a resolution had been adopted which was absolutely opposed to the resolution which the Colleges now communicated to the Society. It was undoubtedly the desire of the profession that there should exist only one examining body in London, and this desire had been disregarded by the Colleges.

Mr. PARKER YOUNG thought that it was not easy to determine upon a resolution at so short a notice. He questioned whether it would not be more dignified to receive the communications of the Colleges in silence. Such regret as would be felt concerning the decision of the Colleges would not appropriately come from the Society with regard to its own interests, for those were secure; but would come better from the profession generally and the public, whose interests had not been considered by the Colleges.

Mr. GEORGE BROWN also felt that so far as the position of the Society was concerned there was no reason to regret the action of the Colleges. The Society could confer far greater privileges than could the Colleges, and it had a future before it of more usefulness to the profession and the public. Among other courses, he thought the amalgamation with the examining board of a provincial university would be desirable.

Mr. CHABOT thought the meeting might not improperly express regret at the delay of the Colleges in replying to the letters of the Society. This reply, moreover, was not as courteous as it might be.

Mr. HART said that the meeting had to decide upon the course it should take in the interest of the public and of the profession, and he warmly supported the resolution Mr. Barnes had proposed.

Mr. YOUNG considered the meeting should request the Society to place itself in communication with other examining bodies, and in the event of no arrangement being arrived at then to apply to the Medical Council.

The meeting then unanimously adopted the resolution proposed at the beginning of the meeting. A further resolution was unanimously passed, to the effect "that a copy of this resolution, together with a copy of the correspondence and a statement of the facts, be published, and also circulated among the licentiates of the Society, and a memorial forwarded for their signature, expressive of their views on this important subject."

A vote of thanks was accorded to the Master, and the meeting terminated.

At a meeting of the Council of the Metropolitan Counties Branch of the British Medical Association, held last Wednesday, a requisition was presented signed by twenty members of the branch, calling for a special general meeting to discuss the questions of the exclusion of the Apothecaries' Society from a share in the Conjoint Examining Board in England, and also of the representation of licentiates and members on the governing bodies of the Colleges of Physicians and Surgeons. The Council, in complying with the requisition in accordance with the bye-laws, refrained from expressing any opinion upon the subjects to be brought forward at the meeting, which will be held at the School of Mines, Jermyn-street, on Dec. 3rd, at 8 P.M.

SANITARY INSTITUTE OF GREAT BRITAIN.—At an examination held on Nov. 11th and 12th, sixty-four candidates presented themselves—nine as local surveyors and fifty-five as inspectors of nuisances. Of the former class four, and of the latter forty-two, obtained certificates of competency.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Scarlet Fever at Wombwell, by Dr. PARSONS.—The district of the Wombwell Local Board of Health within the Barnsley Registration district has recently been inspected owing to a prevalence of scarlet fever. Like most of the reports issued from the department, the one under consideration deals at length with the character of the district and its population, both from a general and a sanitary point of view; and it is shown, amongst other things, that on a population varying from 8451 to 10,418, the scarlet fever rate per 1000 during the five years 1881-85 was 2·32 in Wombwell as opposed to 0·43 in England and Wales. All cases do not come within the knowledge of the medical officer of health, but in the latter half of 1884 he knew of 250 cases and 41 deaths, and in 1885 there were some 300 with 46 deaths; the disease continuing into 1886. In considering the causes which went to favour such a wide spread of infection, Dr. Parsons refers to houses being too thickly populated; to unpaved and uncleanly condition of yards; to a scarcity of water, leading both to uncleanliness and to a needless aggregation of children around the pumps where water was to be had; and to the absence of any means for isolating first attacks of fever. As regards the water-supply, we note that any difficulty as to the quantity needed has since been overcome by reason of a legal decision in favour of the Local Board; but the question as to a hospital is by no means a hopeful one for the authority are apparently convinced that it would not be used even if provided. Dr. Parsons recommends them to study this part of the question by the light of the official report on the Use and Influence of Hospitals for Infectious Disease, where it will clearly be seen that, in nearly every instance, all that is required to secure resort to hospital is to have a reasonably attractive small building maintained in a state of efficiency and readiness for actual use. In the absence of such provision the authority have trusted largely to a system which is in vogue in certain parts of Kent—namely, the employment of so-called "disinfecting nurses," who visit the houses, attend to the sick, and especially see that all needed measures of disinfection are taken. How far the system may have answered in individual cases it would be unfair to judge; and even as regards the whole epidemic nothing decisive can be said as to this, unless we knew the number of the nurses employed, and the date during the outbreak when the system first came into operation. But the mere fact that some 550 cases and 86 deaths took place in eighteen months would rather tend to show that, from some cause or other, the means taken to stay the spread of the disease practically broke down. The plan has also the additional disadvantage that the cost it involves has to be smuggled under some other name than nursing, which is not provided for, except at a hospital, under the ordinary provisions of the Public Health Act.

Scarlet Fever at Hindley, by Dr. PARSONS.—After a general description of the various sanitary conditions influencing health in the district, Dr. Parsons shows, by means of a statistical table, how high the mortality from scarlet fever has been in the district, the average annual rate for the past ten years being 1·68 per 1000, as opposed to 0·55 for England and Wales as a whole; the disease has also shown a tendency to recur in an epidemic form every four years, such recurrence doubtless being largely dependent upon the accumulation in the intervals of children who are susceptible of the disease through not having been protected by a prior attack. In 1877 there were 53 deaths from this disease, in 1880 there were 86, and in 1884-85 there were 57, in a population which in 1881 had reached 14,715. In seeking a cause of this prevalence, it was found to be quite useless to go beyond the agency of conveyance of the poison from sick to healthy by the channel of personal intercommunication, and instances are quoted to show the utter carelessness of the mining population in exposing the healthy to the sick. Yards and privies in common to more than one house tend also to the aggregation of sick and healthy children, and party walls between adjacent houses not being carried up to or through the roof-leads to a common space under the roof which is general to all houses in the row. Dr. Parsons also refers to the fact that a good many dwellings have sink-pipes through which drain air can come up into the houses, and he regards it as possible that water in which the person and clothes of scarlatina patients have been washed, and which will be impregnated with the scales from the skin, may give an infectious character to the drain air of such channels as receive this water, and that through this means scarlet fever may spread from one house to another. And, again, the Local Board of Health have no means for disinfecting infected articles, nor any means for the isolation of the sick. Under such circumstances they are obviously without the essential provision for performing their duty as a sanitary authority in checking infectious disease and death.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5854 births and 3407 deaths were registered during the week ending Nov. 13th. The annual death-rate in these towns, which had been 19·3, 18·5, and 18·2 per 1000 in the preceding three weeks, rose again last week to 19·5. During the first six weeks of the current quarter the death-rate in these towns averaged 19·0 per 1000, and was 1·9 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 13·9 in Brighton, 15·1 in Sunderland, 15·9 in Derby, and 16·4 in Birkenhead. The rates in the other towns ranged upwards to 26·1 in Wolverhampton, 27·3 in Preston, 28·0 in Halifax, and 30·0 in Oldham. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding nine weeks from 1202 to 368, rose again last week to 411; they included 91 from scarlet fever, 81 from measles, 80 from diarrhœa, 69 from "fever" (principally enteric), 46 from diphtheria, 44 from whooping-cough, and not one from small-pox. No death from any of these zymotic diseases was recorded last week in Blackburn, whereas they caused the highest death-rates in Cardiff, Halifax, and Wolverhampton. The greatest mortality from scarlet fever occurred in Liverpool, Sheffield, Salford, Oldham, and Bristol; from measles, in Portsmouth, Leeds, Wolverhampton, and Halifax; from "fever," in Halifax, Plymouth, Preston, Derby, and Cardiff; and from whooping-cough, in Oldham. The 46 deaths from diphtheria in the twenty-eight towns included 23 in London, 6 in Liverpool, 3 in Portsmouth, 3 in Birmingham, 2 in Nottingham, 2 in Manchester, and 2 in Oldham. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 295 and 293 in the preceding two weeks, rose last week to 321, but were 118 below the corrected average. The causes of 95, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Preston, Blackburn, Bolton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Leicester, Bradford, Sheffield, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·2, 18·6, and 22·1 in the preceding three weeks, declined again to 20·1 in the week ending Nov. 13th; this rate was 0·6 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 9·8 in Perth and 13·4 in Dundee, to 23·3 in Glasgow and 23·4 in Paisley. The 497 deaths in the eight towns last week showed a decline of 48 from the number in the previous week, and included 23 which were referred to scarlet fever, 21 to diarrhœa, 17 to whooping-cough, 11 to diphtheria, 7 to "fever" (typhus, enteric, or simple), 2 to measles, and not one to small-pox; in all, 81 deaths resulted from these principal zymotic diseases, against 83 and 73 in the preceding two weeks. These 81 deaths were equal to an annual rate of 3·2 per 1000, which was 0·8 above the mean rate from the same diseases in the twenty-eight English towns. The deaths from scarlet fever,

which had been 24 and 16 in the preceding two weeks, rose again last week to 23, of which 16 occurred in Glasgow, 3 in Dundee, and 2 in Edinburgh. The 21 deaths attributed to diarrhœa corresponded with the number in the previous week, and included 7 in Glasgow, 7 in Edinburgh, and 3 in Dundee. The fatal cases of whooping-cough, which had been 28 and 15 in the previous two weeks, rose last week to 17; 11 were returned in Glasgow, 4 in Aberdeen, and 2 in Edinburgh. The 11 deaths referred to diphtheria showed a further increase upon recent weekly numbers, and included 5 in Glasgow, 3 in Edinburgh, and 2 in Aberdeen. The 7 deaths from "fever," including 3 in Glasgow and 2 in Edinburgh, corresponded with the number in the previous week. Both the fatal cases of measles occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 79, 96, and 118 in the previous three weeks, further rose last week to 123, but were 3 below the number in the corresponding week of last year. The causes of 76, or more than 15 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 20·5, 21·9, and 26·2 per 1000 in the preceding three weeks, declined again to 23·6 in the week ending Nov. 13th. During the first six weeks of the current quarter the death-rate in the city averaged 23·0; the mean rate during the same period was 17·2 in London and 18·8 in Edinburgh. The 160 deaths in Dublin last week showed a decline of 17 from the number in the previous week, and included 15 which were referred to scarlet fever, 3 to "fever," 3 to diarrhœa, 2 to whooping-cough, and not one either to small-pox, measles, or diphtheria. Thus 23 deaths resulted from the principal zymotic diseases, against 23 and 32 in the previous two weeks; they were equal to an annual rate of 3·4 per 1000, the rates from the same diseases last week being but 1·8 in London and 3·3 in Edinburgh. The fatal cases of scarlet fever, which had been 7, 10, and 8 in the preceding three weeks, rose last week to 15, and exceeded the number in any previous week of this year. The deaths from "fever" and diarrhœa, on the other hand, showed a considerable decline from recent weekly numbers. Three inquest cases and one death from violence were registered; and 46, or more than a quarter, of the deaths occurred in public institutions. The deaths of infants showed a decline, and those of elderly persons a further increase upon recent weekly numbers. The causes of 19, or nearly 12 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Major Espine Charles Robert Ward has retired upon temporary half-pay, on account of ill-health; Surgeon Charles Henry Swayne, to be Surgeon-Major; Deputy Surgeon-General Samuel Fuller is granted retired pay, with the honorary rank of Surgeon-General.

ADMIRALTY. — The following appointments have been made: Fleet Surgeon Stephen Sweetnam, to the *Duke of Wellington;* and Fleet Surgeon Edward Doyle, to the *Penelope.*

ARTILLERY VOLUNTEERS.—1st Cheshire and Carnarvonshire: Robert Langford Jones, Gent., to be Acting Surgeon. 2nd Middlesex: Arthur Henry Robinson, Gent., M.D., to be Acting Surgeon.

ENGINEER VOLUNTEERS. — 3rd Tower Hamlets (East London), Robert Hugh Hodgson, Gent., to be Acting Surgeon. — The Volunteer Submarine Miners (the Severn Division): The undermentioned officer, amongst others, has been transferred from the 1st Gloucestershire (the Western Counties) Engineer Volunteer Corps:—Acting Surgeon John Hugh Rees, M.B., to be Acting Surgeon.

DEATH UNDER CHLOROFORM. — An inquest was recently held at the Manchester Workhouse, Crumpsall, on the body of a man who died while under the influence of chloroform, administered for the performonce of an operation. The jury returned a verdict of "Death from misadventure," and were of opinion that the drug had been skilfully and properly administered.

Correspondence.

"Audi alteram partem."

DIRECT REPRESENTATION OF THE PROFESSION ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—I have read over my letter again, but find nothing in it "unfair," and cannot therefore accept Mr. Ker's suggestion to withdraw it. On the contrary, I consider it "unfair" of Mr. Ker to misquote my words. I did not mention Mr. Wheelhouse, I spoke of *the Committee* which Mr. Ker represents "as acting in opposition," &c.

The election is virtually over, and it is useless to enter into Mr. Ker's explanation. He acknowledges that "the matter dropped." Why? I say because anyone could see that the proposal was against the sense of the meeting. It was so on both days, and therefore the Council, I consider, was not justified in adopting a resolution which the general meeting could not be persuaded to sanction. If such proceedings are to be countenanced—and Mr. Ker and Dr. Carter took care to advertise this resolution in order to influence the election—we may as well hand over all matters to the Council and regard representation in the Association as a hollow pretence.

I am, Sir, yours obediently,
HENRY W. WILLIAMS, M.D.

Chapel-place, Cavendish square, W., Nov. 15th, 1886.

To the Editor of THE LANCET.

SIR,—May I ask you to find space for the subjoined letter, which I have addressed to Dr. Waters, respecting the enclosed circular which I have just received from him?

I am, Sir, yours truly,
FREDERICK J. GANT.

Connaught-square, W., Nov. 15th, 1886.

"Connaught-square, Nov. 15th, 1886.

"DEAR SIR,—With reference to your circular respecting the special qualifications of Sir W. Foster and Mr. Wheelhouse as candidates for election to the Medical Council, I think it due to yourself that I should acknowledge in some way the copy of the circular which I have just received.

"No man is so highly entitled as you are to influence the profession with regard to this question, although I suppose that in this, as in other matters, all thoughtful men will act for themselves. I feel strongly that the direct representatives of general practitioners in the Council should consistently themselves be general practitioners, that they may not only know, but be also personally identified with, their professional position, their claims, and their wants.

"In this light only can there be any justification for the enlargement of an already overgrown Medical Council, and which, chiefly on that account, is almost practically useless for the good of the profession.

"Believe me, dear Sir, very faithfully yours,
"FREDERICK J. GANT.

"Dr. E. Waters, Ex-President of the British Medical Association."

To the Editor of THE LANCET.

SIR,—It is greatly against my inclination to have even the appearance of a difference with an old friend whom I have known so long and so much respected as Mr. Balding, but the letter from him which appeared in your last week's issue places me in such a false position that I have no other alternative but to ask you to publish the subjoined.

On the 2nd or 3rd instant I received a copy of an address from Mr. Balding announcing that he was a candidate for a seat on the General Medical Council. It had been arranged to call a meeting of the Council of the Poor-law Medical Officers' Association on the 4th at 5 P.M., at my house, as I was too infirm to go out. At about 4.30 on that day Mr. Balding was announced. On expressing my surprise at his coming so early, he said he had left the College meeting, as he wanted to have a talk with me about the election, when I at once said, "You have no chance; you are too late. How much I regret you did not come out earlier; our Association would have supported you." He replied: "I have been prevented by sickness in my family, but I

mean to go on now; indeed," said he, "I have called before the meeting, as I do not wish our friends to know I have asked you to nominate me," at the same time producing a nomination paper, on which I said, "I cannot do that; it would be inconsistant for me to do so, as I have publicly recommended Foster, Glover, and Wheelhouse." He replied, "I do not see that you cannot nominate me and still vote for your friends. I want your name." I again strongly objected, but on his stating that it would not be publicly known that I had nominated him, I reluctantly assented. At this conversation no regret was expressed by me that my letter to you of the 30th had been reprinted, and was in process of circulation, for the reason that the merest tyro in electioneering proceedings should be aware that when once a letter has appeared in a public journal, it is competent for anyone, whether friendly to the candidate or not, to deal with such letter as he or they may think fit, so long as the text is quoted correctly. At the subsequent meeting of the Council, no objection was raised to my having written such a letter, nor any insinuation made that I had abused my position as President in writing it, or had written in the name of the Association, as Mr. Balding's and Mr. Cornwall's letters would appear to infer. If such insinuation had been made, it would at once have been indignantly repudiated by

Yours obediently,

JOSEPH ROGERS.

Montague-place, Russell-square, Nov. 16th, 1886.

To the Editor of THE LANCET.

SIR,—I have just received circulars in the name of the British Medical Association, accompanied by the card of one of the secretaries to the Metropolitan Counties Branch, advocating the candidature of Messrs. Foster and Wheelhouse for the General Medical Council. I protest against any such use being made of the influence of the Association generally, or of that of its branch secretaries individually, as a cheap form of advertisement; it is undignified, and, as all the candidates are members of the Association, it is manifestly unjust. It is not a question of the Association candidates as against non-associationists, but of consultants *versus* general practitioners.—I am, Sir, your obedient servant,

Old Burlington-street, W., Nov. 16th, 1886. GEORGE STOKER.

*** Our correspondent is in error in stating that all the candidates are members of the Association.—ED. L,

---

THE BRIGHTON MEETING AND DIRECT REPRESENTATION.

To the Editor of THE LANCET.

SIR,—I withdrew my amendment at the Brighton meeting and seconded Dr. O'Connor's proposal, and was astonished to read the account in the journal. Sir Walter Foster immediately left the chair without putting the resolution. It was unnecessary to do so, as the meeting was so evidently in favour of it. No one could anticipate the attempt now made to throw doubt on the result of the vote. It was understood by all present that the Association was pledged to neutrality. Mr. Ker states that his committee carried out Dr. Dolan's idea of a *plébiscite*. Surely not. I proposed taking the vote of over 12,000 members of the Association. Mr. Ker and his friends took a vote of 340, most of whom were members of the Council or friends of those who started the provisional committee. A vote from such a committee was a foregone conclusion as regards the independent candidates. Out of the 340 I should like to know how many actually voted. I remain, Sir, yours truly,

Halifax, Nov. 15th, 1886. T. M. DOLAN, M.D.

To the Editor of THE LANCET.

SIR,—As my name appears in THE LANCET of the 13th inst. in a letter from Mr. Ker in connexion with what he alleges took place at the recent Brighton meeting of the British Medical Association, with reference to the selection of candidates for direct representation on the General Council, will you allow me to state my very *distinct* recollection of what actually occurred at the general meeting on August 11th? Dr. Carter moved that three names be selected by the Council; after some discussion on this point, Dr. Dolan proposed an amendment which was practically a dilution of Dr. Carter's motion, to which so much opposition was shown by those present that Dr. Carter withdrew it *on the ground that the general feeling was against his suggestion.* Dr. Dolan's amendment then became the substantive motion before the meeting (which at this time numbered at least, if not more than, two hundred members), and as an amendment to it, I moved that the Association take no action whatever in the matter. This proposal was received with an outburst of cheering by those in the body of the hall. Dr. Dolan thereupon withdrew his resolution *in order to second my amendment, which was immediately unanimously carried.* The Chairman, Sir W. Foster—*not* Dr. Withers Moore, the President—said "That settles it," and the meeting then broke up.

Mr. Ker states that my amendment was not seconded? Assuming for a moment that this was so, *why* did Dr. Dolan withdraw his resolution? I remember reading, a few days after the meeting, the *British Medical Journal* report to which Mr. Ker refers. It struck me as being very meagre and not strictly accurate. Yours faithfully,

Nov. 15th, 1886. BERNARD O'CONNOR.

THE RELATION OF THE COURT OF EXAMINERS TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of THE LANCET.

SIR,—In the report of my speech at the recent general meeting at the College of Surgeons, I am represented as advocating the representation of every medical school by examiners *on the Council of the College.* Whilst in favour of the principle of representation of schools on the Boards and Court of Examiners, as well as of election of examiners, as one of the Charters of the Irish College of Surgeons has it, "without hatred, evil will, partiality, affection, favour, or fear," I have always held the view of THE LANCET, that the Council and Court of Examiners should be separated. No Fellow or member of the Senate of the University of London is eligible as an examiner, and at the Royal College of Surgeons in Ireland examiners are incapable of being elected members of the Council, and members of the Council are ineligible as examiners. The large sum annually divided amongst the members of the Court of Examiners increased, as it will be by the operation of Sir Erasmus Wilson's bequest, will render it practicable to deal justly and equally with all the medical schools, a few of which might be amalgamated with advantage. In expressing views of this kind *en passant* at the meeting, I did so in the capacity of an entirely independent Fellow, making observations strictly relevant to the report of the Council then submitted to the meeting for criticism, because this was the only occasion on which I should enjoy the opportunity of speaking openly and without reserve. My remarks would also have been quite relevant to the more immediate matter in hand if I had added, as I intended to do, that the presence of representatives of the Members of the College on the Council was shown to be desirable by the very obvious fact that on all such questions they would be absolutely impartial.

I am, Sir, yours, &c.,

Nov. 15th, 1886. WALTER RIVINGTON.

THE FUTURE POSITION OF THE SOCIETY OF APOTHECARIES.

To the Editor of THE LANCET.

SIR,—It is with both surprise and indignation that we hear that the Council of the College of Surgeons sent last Tuesday a letter to the Society of Apothecaries, expressing its adherence to the policy of excluding the latter body from the Conjoint Scheme. Previous to the memorable general meeting of the College of Surgeons on the 4th inst., a report was in circulation to the effect that the Council of the College would not view unfavourably such a resolution as that bearing upon the question of union with the Apothecaries' Society; and most decidedly that general meeting gave clear expression, by a vote carried *nem. con.*, to the views of the diploma-holders of the College, that it would be most detrimental to the interests of their *alma mater* should the Council still maintain its policy of exclusion. In the short interval of twelve days between the general meeting of the College and the transmission of its letter to the [illegible] Hall, the Council can

neither have had the time nor the opportunity to collect evidence sufficient to justify it in its latest decision. Whose are the interests the most vitally concerned in this question: those of the select body of pure surgeons who sit on the Olympian heights of Lincoln's-inn-fields in a temple raised to other gods, or the general body of the profession which has been relegated to the outer courts? A clear and sharp issue was raised, and an emphatic decision arrived at on the 4th inst.; yet the Council persists in its suicidal resolve to lift no finger to avert an impending catastrophe. When a second corporation has been permitted to grant complete and competing licences in medicine, midwifery, and surgery, within a stone's throw of the College walls, the medical profession will not forget with whom to lay the blame. At the general meeting the Council was requested to report upon this matter "at a future meeting of Fellows and Members to be summoned for the purpose at an early date." That date must be at once.

We are, Sir, your obedient servants,

WARWICK C. STEELE,
W. M. ASHTON ELLIS,
Hon. Secs. Association of Members of Royal College of Surgeons.

P.S.—With reference to our letter appearing in your last issue, we have been asked as to where communications and signatures to the petition of the members of the Royal College of Surgeons should be sent. We take this opportunity of stating that all correspondence should be addressed to us at the Western Dispensary, Westminster, S.W.

To the Editor of THE LANCET.

SIR,—I have read most carefully the accounts given by you and by your contemporaries as to the dilemma in which the profession is supposed to be placed if the Colleges of Physicians and Surgeons do not admit the Apothecaries' Society to a partnership in the Conjoint Examining Board in England. Two questions have arisen in my mind, for plain answers to which I should be obliged, as I shall be materially influenced thereby in my attitude to many of the medico-political questions which are now being forced on our attention.

1. Is not a licentiate of the Society of Apothecaries, *who has taken no other diploma*, at the present time in every practical sense a practitioner of an inferior grade? I refer not to men of thirty or forty years' standing, when the L.S.A. stood in the fore-front, and was an honoured distinction; but to him who has acquired this one qualification only during the past ten or fifteen years, and practises his profession on this diploma only. If he is of an inferior grade, why make this noise? Let us reconcile ourselves to the fact.

2. Will the representatives of the Apothecaries' Society, if admitted to a Conjoint Board, endeavour to keep up the present standard or try to lower it? If the latter, they had better be excluded, and I am not aware that anyone has argued that their admission is necessary, or even advisable, for the former object.

If the Society must be admitted solely for the sake of the penal clauses of the Medical Act, as you seem to urge, then I can only lament over the loss of many well-considered Medical Bills, and the indecent haste with which, for the sake of direct representation only—a mere will-o'-the-wisp and caucus-driven absurdity—the new Medical Act has been rushed through Parliament by our medico-politicians. The lost Bills insisted on a one-portal system, which is the best guarantee for the future of our profession; this Bill has made it impossible. Yours very faithfully,

Nov. 15th, 1886. L.S.A. (with other qualifications).

GERMAN MEASLES.

To the Editor of THE LANCET.

SIR,—I beg for insertion of the following account of an epidemic of German measles on the ground of its being a valuable contribution to the literature of the subject, and perhaps all the more valuable as the product of the observation of one who is not medical, and therefore not obnoxious to the suspicion of bias.

A friend of mine, a clergyman, the head master of a large country school, in a letter he wrote to me a short time ago, says: "We have had a course of epidemics lately: we began the year with mumps; the next term we had German measles; and this term we have common measles of rather a bad sort—31 cases, about half-a-dozen of them rather bad. We find that German measles is no protection against ordinary measles, but of all our cases of measles only one boy has had a second attack. Out of 105 boys, 70 have had measles before; so far 69 have escaped. Of the remaining 35, 31 have got measles so far." Having lately seen a few cases of probable German measles, and being interested in the subject, as I have never had the opportunity of watching an epidemic of this disorder, I wrote to my friend for further particulars, especially inquiring as to the occurrence of measles in those who had had the German malady. I subjoin his answer *verbatim*, suppressing only names of persons and places:—

"What we had last term was said to be ordinary measles of a mild sort, but I, with great presumption, maintained that it was not, and called it German measles. When I was at —— school in 1868, we had a precisely similar epidemic, and I remember that —— (the doctor) called it 'spurious or German measles.' The boys were usually kept in for three or four days, and, just as in the epidemic here, none of them were ill. My reasons for believing the late epidemic here not to be ordinary measles were: 1. The boys were none of them really ill; the worst case out of forty was hardly as bad as the mildest case of ordinary measles. 2. In the majority of cases there was no cough, no sore-throat, no weakness of the eyes, no cartarrh; some few, however, of the patients had 'sneezing' for a day before the rash appeared, and when the rash came out their eyes were rather bloodshot, but not running. 3. The rash, judging from forty cases, is much smaller than the ordinary measles rash, but it is like it in form in the worst cases. (It consisted of very definite spots, round and crescent-shaped, which did not run into one another or form blotches). 4. There was none of the characteristic *smell* of measles which is always patent to my nostrils. 5. In a large number of cases the boys would not have known that they had any disorder if they had not been on the look-out for the rash. 6. The strongest point against the complaint being measles is that the period of incubation is much shorter. This is, of course, a difficult point to establish; but the time at which the boys came in one after another pointed to this; and one boy who came to school after the term began developed the rash *four or five days* after he came back. This last point, of course, is somewhat in favour of the scarlatina theory. One or two boys also had slight sore-throat. In one or two cases the eruption was suspicious, the spots being very small, and there being some slight appearance of a blush over the chest.

"Against the scarlatina theory I note:—1. That out of the forty cases there was not one severe enough to give a suspicion of scarlatina, apart from the appearance of the rash in two cases. 2. In one of those two cases there seemed reason to believe that the rash was different, as the boy had it twice during the term, and once again during the holidays, and his friends said that he had had it once or twice before in hot weather. 3. After the epidemic was over, one boy who had had the 'German measles' eruption did actually have scarlatina; that is to say, although he was not ill and had only a slight sore-throat, he had unmistakably the scarlatina rash. It was about as mild a case as could be, but yet it was in my opinion, and in that of the doctor, clearly different and distinguishable from all the cases of what I called German measles.

"To my mind the rash of German measles is as different from scarlatina rash as the rash of ordinary measles is. I have only twice come across German measles—in 1868 and in 1886. I believe I have seen a great many cases of measles and a fair number of scarlatina. To my lay observation it is different from both. The differentia of the German measles rash, as distinguished from scarlatina rash, is that the spots are clear and definite, and slightly raised, with white skin between them; and although scarlatina rash is spotty sometimes, the spots are not definite in the same way. I remember seeing it stated in the *Saturday Review* that German measles is 'a cross between scarlatina and the domestic variety of measles.' I am told that this is an exploded theory, but there is a great deal superficially in favour of it; at any rate, the complaint has some of the characteristics of both diseases. I believe it to be a disorder *sui generis*; but you will rightly discount all that a layman has to say on these points. Out of thirty-three

boys who have now had measles, ten had German measles last term; and this is almost the exact percentage of cases in the whole school—viz., forty out of about 120. It seems evident that German measles is no protection against 'the domestic variety.' This is a long story, but, as you know, I have a weakness for dabbling in these matters."

I can endorse my friend's remark about the measles *smell*. I think in most cases it is highly specialised. I would add that the writer of the above letter has never studied medicine, nor read much in medical books. But he has been a very observant schoolmaster for many years, is of a thoroughly scientific turn of mind, and took honours in Greats at Oxford at a time when Mill's Logic was almost the Bible of the "ambitious." I am, Sir, yours faithfully,

London, Nov. 4th, 1886. H. B. DONKIN.

ARE SMALL-POX AND COW-POX ONE AND THE SAME DISEASE?

To the Editor of THE LANCET.

SIR,—For many years now, the medical profession in this country seems to be generally agreed that human variola and cow-pox are one and the same malady, the latter being merely small-pox modified through transference to the bovine creature. In books, letters, and lectures there is evidence of this belief, and the latest proof of its existence is to be found in the Harveian Oration recently delivered by Dr. Pavy, in which we find the following statement: "It may now be regarded as an accepted conclusion that vaccine lymph is the virus of small-pox, modified by transmission through the cow." If it be not rank heresy to throw doubts on a conclusion accepted by such high authorities in human medicine as Dr. Pavy represents, will you kindly allow me, a very humble student of animal medicine and comparative pathology, to dissent from this generally accepted conclusion, and to express strongest doubts, or even entire disbelief, as to the one malady being merely a modification of the other. The question would not, perhaps, be of so much moment had not at least three serious accidents resulted from carrying the above conclusion into practice; and as more disasters may yet be due to the same notion, I submit that it is high time the supposed facts upon which it is based should be examined, in order that the truth may be arrived at. The most notable authority for the statement made by Dr. Pavy, in this country at least, was my old friend, the late Mr. Ceely of Aylesbury, who reported that he had succeeded in producing cow-pox by inoculating a cow with small-pox matter. But it must be remembered that he, at the same time, was experimenting with vaccine lymph, and the great probability is that he employed the latter when he thought he was using the former. At any rate, he never afterwards succeeded in repeating his presumed success, though his subsequent trials were made under the most favourable conditions. The last attempt was undertaken not long ago, and only a short time before his death. On that occasion, twelve heifers were purchased by the Local Government Board and lodged in the Brown Institution, where they were inoculated by Dr. Klein, under the supervision and direction of Mr. Ceely; and though small-pox matter was literally poured into the incisions, and the greatest care was observed throughout, yet cow-pox was not developed in any of the animals. Similar failures have attended all other attempts, when these have been made openly and by two or more individuals. I may allude to those of the French Commission, which included some of the most distinguished members of the medical profession in Paris, with the able veterinary surgeon, Chauveau, as operator; and the Italian Commission, whose labours were carried on at Turin on a large scale and for a long time. All in vain, however, for small-pox could not be converted into cow-pox; and the conclusion arrived at was in direct opposition to that which Dr. Pavy asks us to accept.

Dr. Pavy speaks of the small-pox virus becoming attenuated in the cow, and that this attenuation manifests itself as cow-pox. But if inoculation of the former produces the latter, then I contend it is not attenuation, but absolute and permanent transformation of the most startling and complete description, and such as cannot be effected with any virus or microbes known. We are required to believe that by one remove of human small-pox—a most infectious, fatal, and generally eruptive disease—to the cow, we have produced a non-fatal disease, which can only be transmitted by inoculation, with an eruption quite localised at the points of inoculation, and otherwise widely different in its clinical and pathological features, especially with regard to the eruption. Most astonishing of all, however, is the circumstance that this modified or attenuated small-pox, when carried back to its original soil in mankind, never resumes its original characteristics; no matter though it be carried through countless generations of human beings, it remains for ever in its transformed condition. This does not happen with an attenuated virus, nor can any virus, by any artifice of man, become so utterly changed. Again, we all know how readily vaccine lymph, when inoculated in the calf or cow, will produce vaccinia. As I have pointed out, all attempts to develop the latter by inoculating these animals with variolous matter have resulted in failure, when made by those most competent to achieve success, if this were possible.

Surely for these reasons it is, to say the least of it, rash and dangerous to conclude that the vaccine lymph is the virus of small-pox modified by transmission through the cow. But if Dr. Pavy or anyone else will publicly demonstrate the identity of the two diseases by the most convincing of all evidence, then I, with the large number of medical men on the continents of Europe and America who hold the opinion I do, shall gladly reconsider my position in the discussion. In the series of papers on "Human and Animal Variolæ" which you did me the honour of publishing a few years ago, I stated that small-pox and cow-pox were different and antagonistic diseases, and nothing has transpired since then to cause me to change my views; on the contrary, the important discoveries which have been made in microbiology (if I may use the term) have confirmed them in every respect.

I remain, Sir, yours truly,

GEORGE FLEMING, I.L.D.,

Nov. 8th, 1886. Principal Veterinary Surgeon of the Army.

CASE OF SPINA BIFIDA SUCCESSFULLY TREATED BY OPERATION: A REJOINDER.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 2nd Mr. Barton of Dublin published the notes of a case with the above heading. Being absent from town at this date, I have only just read these notes, and beg permission to say a few words in reply. In the first place I would congratulate Mr. Barton on the success of his procedure as a surgical operation; but from every other point of view I consider the method adopted as the one of all others least likely to be of real service to a patient with spinal bifida. Mr. Barton quotes from my article in Heath's Dictionary of Surgery; he confirms by his case some of the diagnostic points there given between meningocele and myelocele, and further shows that the freedom from paralysis is not diagnostic of the latter condition. In describing the operation, it is stated that numerous small nerves passed "into the portion removed, which were of course cut across." I feel sure it will interest Mr. Barton to know that the nerves found within the sac do not pass *into* the sac wall, but that they *arise from it;* and that the median vertical portion of such a spina bifida as the one he describes represents the spinal cord—in fact, that it is the spinal cord modified by the pressure to which it has been subjected. Mr. Barton's operation was therefore equivalent to removal of a portion of the spinal cord. Under such circumstances ultimate success was impossible. I agree with him in his statement that "the treatment of spina bifida is still unsettled." The committee of the Clinical Society of London, which recently reported on this subject, also appeared to think that this question of treatment was not yet settled; but it was laid down by that committee almost as a canon "that any operation involving interference with or removal of the *median vertical portion* of the tumour should be abandoned."

I have written this less in criticism of Mr. Barton's procedure, which was eminently successful considered merely as an operation, than in the hope of dissuading others from following his example.

I am, Sir, yours obediently,

ROBERT WILLIAM PARKER,

Surgeon, East London Hospital for Children.

Old Cavendish-street, W.

ASSOCIATION OF GENERAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—We ask leave to inform your readers that active steps have been taken by the Association to assist general practitioners of this country to give combined and united force to their wishes and interest, especially in relation to the actions of the various corporations, and to the representation of the general practitioner thereon. We desire especially at this moment to assist the licentiates of the College of Physicians to give organised expression to their claim to a voice in the administration of the affairs of their College. We believe their claim to be so strong that adequate representations made by a strong body of licentiates duly organised could not fail ultimately to secure for the licentiates of the College of Physicians a just voice in the management of their own affairs, and in the government of the profession of which they constitute so large a proportion. We should be glad to hear from licentiates of the College of Physicians on this subject, and have names of those willing to take part in securing for themselves and fellows a less contemptuous and more honourable treatment than they now receive at the hands of the self-elected Council of that body. May we be allowed to add that we forwarded yesterday a requisition signed by twenty members of the Metropolitan Counties Branch to the secretaries of the branch calling for a meeting of the Metropolitan Branch to consider the action of the College of Physicians and College of Surgeons in respect to the Apothecaries' Society, which threatens to create a new and competing class of general practitioners throughout the kingdom? We have every reason to believe that that requisition will be favourably considered, and we trust that general practitioners will largely attend the meeting when summoned. Hoping to hear from all who sympathise with our efforts in the objects we have stated,

We remain, Sir, your obedient servants,

H. W. VERDON, M.D., F.R.C.S.,
410, Brixton-road, S.W.
W. GIBSON BOTT, L.R.C.P. and M.R.C.S,
414, Clapham-road, S.W.
Hon. Secs. Association of General Practitioners.

Nov. 18th, 1886.

"DEATH OF A PASTEUR PATIENT."

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to correct a statement in Dr. Hime's letter to you on a Pasteur patient (Wilde), the remarks being made in a postscript that Wilde was not really intentionally bitten by the deceased Oates. I emphatically contradict this hazy piece of information. *Wilde was savagely bitten by Oates*, and the latter had remarked that he should bite someone if they did not mind. I saw the lacerated teeth-marks. I had Wilde's own evidence and my own observations bore out the man's statement. I had several opportunities of questioning Wilde on this point; his statement was always the same. If there had been any doubt in my mind that it was an abrasion only in the struggle, he would never have gone to Paris. This interpolation of Dr. Hime's letter in your annotation also gives an utter misrepresentation of the facts of the case.

I am, Sir, yours obediently,
HARRY O'D. FOOTE, M.D.

Nov. 1886.

THE MEETING OF GERMAN NATURALISTS AND MEDICAL MEN IN BERLIN.

(Concluded from p. 847.)

AT the first meeting of the Surgical Section Professor von Bergmann showed some interesting and rare cases. One of these was a young man who from a fall received compound fractures of the legs and fractures of both the thigh and the patella. In order to unite the fractured patella, some months after the accident, Professor Bergmann chiselled off the tuberosity of the tibia, and placed it between the two fragments of the patella, after which union took place. The patient can now extend the leg very freely, but the mobility of the knee is yet a good deal impaired. The other cases shown were two cases of Actinomycosis. At the second meeting, Krause spoke of the changes in the nerves and in the spinal cord after amputation, and afterwards demonstrated his specimens. The changes consist in atrophy of the medullary substance and subsequent atrophy of the axis cylinder in the sensory peripheric nerves; hence the changes spread to the spinal ganglia. As shown before by Dickinson and others, alterations were also seen in the posterior column and in the ganglia cells of the posterolateral group in the anterior horn. The observations were made under the direction of C. Friedländer. Grünfeld showed an Endoscope of simple construction, which enabled him to make out the exact form, surface, and extent of bladder tumours. Madelung introduced the subject of Diffuse Lipomata, and an interesting discussion followed, in which several surgeons spoke of the neuralgic pains associated with these tumours and the recurrence of these tumours after removal. Madelung described an affection of the sole of the foot corresponding to Dupuytren's palmar contraction; and exhibited some casts. Of the other papers read in this section we wish briefly to notice one by Küster on Stenosis of the Trachea. The author distinguished between traumatic, diphtheritic, and syphilitic stenosis and the narrowing produced by new growths (sarcomata and carcinomata), &c., and recommended, whenever possible, removal of the granulations, dissection of bands, &c., and subsequent dilatation by means of instruments. In very severe cases, especially in cases of new growths, he recommends resection of the trachea. Baumgärtner spoke of the Cachexia following the removal of Tumours of the Thyroid. The cachexia is not present in all cases of thyrectomy, and in six cases no cachexia strumipriva resulted. In the discussion which followed, Semon of London gave an interesting account of Myxœdema, of the cases observed in England, and of Horsley's researches. This disease seems as yet to have escaped the notice of German observers. Bardeleben stated that in more than a dozen cases where the thyroid was removed no symptoms of cretinism followed. Others, however, such as Küster, were less sceptical, and advocated only partial removal of the thyroid, except in cases of malignant tumours. Böker related a case of Enchondroma springing from the cricoid cartilage, for the removal of which he extirpated this cartilage, with successful results. The case, which seems unique, has since been published in the *Deutsche Med. Wochenschrift*, No. 43.

In the Medical Section several interesting communications were given. Of these the more important ones were: Runeberg on Pernicious Anæmia produced by Bothriocephalus Latus; Finkler on the Principles of the Pathology and Therapeutics of Fever; and Immerman on Rheumatism. Lenhartz spoke of the antagonism between Morphia and Atropia. His observations and experiments did not lead him to look favourably upon the administration of atropia in cases of morphia poisoning. In 173 cases of opium poisoning 59 cases treated with atropia showed a mortality of 28 per cent., whilst in 73 cases not so treated the mortality only amounted to 15 per cent. In the discussion Freimuth and Lewin spoke in favour of atropia as an antidote in these cases, an opinion which agrees well with the results seen in English hospital practice, many of which are not published, and thus render the statistics of Lenhartz untrustworthy. Penzoldt reviewed the use of Digitalis in various diseases; this drug acts best in simple muscular insufficiency of the heart and in valvular heart disease, and in insufficiency of the right ventricle in emphysema; its effect is more doubtful in nephritis and in the acute diseases associated with weakness from the heart's action; it has little effect also when there is much fatty degeneration of the heart. Cantani gave an interesting communication on the poisonous properties of the Cholera Bacilli. Experiments on dogs showed that if pure cultivations of cholera bacilli in peptone gelatine after having been heated to 100° C. were injected into the peritoneal cavity, symptoms of cholera poisoning appeared; and he argued that the dead cholera bacilli, if absorbed, have a poisonous effect. As therapeutic agents he recommends enteroclysis with hot solution of gallic acid (which destroys the bacilli rapidly), and large hypodermic injections to increase the elimination of the absorbed poison. Strümpell spoke of Compression-myelitis, and expressed the opinion that in these cases there is simple compression of the cord and no myelitis, and often no descending degeneration.

In the Gynæcological Section a number of interesting specimens (preparations of Extra-uterine Fœtation, Ovarian Tumours, and Diseased Fallopian Tubes) were shown, and

many interesting papers were read, such as the one by Rydygier on Vesico-vaginal Fistulæ (twenty-one cases, all but one cured), and E. Fränkel (Breslau) on the Mechanical Treatment of Retro-deviation of the Uterus. This author is against Alexander's operation, where, out of 118 reported cases, three deaths occurred; in fourteen cases no results; in others a pessary had to be permanently worn after the operation; and in many cases sufficient time had not elapsed to speak of a definite cure of the ailment by the operation. Several papers were read on Castration for Epilepsy, for Neuroses, and for Diseases of the Fallopian Tubes. These led to a long discussion, in which the best known German gynæcologists took part, and several (Freund, Olshausen, Schatz) were either opposed to castration for pure neuroses, or advised the operation only in those cases where all other means failed.

In many of the other special sections, such as those of Neurology, Laryngology, Diseases of Children, Forensic Medicine, and Hygiene, excellent work was done; but it is impossible to do justice to the communications in this short report. The most important papers will be published separately in the special journals, as the Association only publishes short abstracts.

In conclusion, a brief reference may be made to the exhibition of scientific instruments and drugs. Besides the usual collection of microscopes, microtomes, electrical apparatus—all by the best German makers,—the exhibition contained numerous physical and physiological instruments, geological charts, and collections of preserved animals, showing the value of new methods of preservation for museum purposes. The specimens exhibited by Prof. Semper (Wurzburg), were beautifully preserved, and the method seemed specially useful for class demonstrations. The exhibition, besides a practical, had thus also an educational value, and we can only recommend the adoption of a similar arrangement to the exhibitions held annually with our Association meeting. An excellent catalogue was prepared and edited by Dr. Lassar, of Berlin, who worked indefatigably for the museum, and took a conspicuous part in the arrangement of the social gatherings and amusements which passed off so successfully. The English visitors are especially indebted to him for the very cordial reception they received, and the assistance he rendered them.

LIVERPOOL.

(From our own Correspondent.)

HOSPITAL SUNDAY AND SATURDAY IN LIVERPOOL.

THE annual meeting in connexion with the Hospital Sunday and Saturday collections was held in the Town-hall on the 5th inst., the late Mayor, Sir David Radcliffe, presiding. As next January will witness the seventeenth anniversary of this movement in Liverpool, it may be regarded as a well-established institution. In further proof of this it may be stated that although the weather last Hospital Sunday was as unfavourable as it could be, and in spite of the depression of trade being then at its worst, the collections realised the total of £6217. In addition to this there were donations amounting to £158; while the Hospital Saturday boxes yielded a total of £3149, an increase of £500 over last year—a most gratifying proof of the increased interest taken in the hospitals by the working men. It was suggested by Sir William Forwood that the Committee should consider the advisability of changing the Sunday from January to May. There was a much larger meeting than usual, and considerable interest was taken in the proceedings.

THE ROYAL INFIRMARY: RESIGNATION OF DR. WATERS.

Dr. Waters, the senior physician to the Royal Infirmary, has resigned the office of physician, which he has held for a period of fifteen years, having been elected in 1871 in place of the late Dr. Inman, who resigned in that year. It is hoped, however, that the infirmary will not lose Dr. Waters' services entirely, but that he will, as consulting physician, be enabled to give the acting staff, students, and patients the benefit of his large experience. There is a growing feeling in favour of making the offices of consulting physician and consulting surgeon really useful, and not merely ornamental, as it must be confessed they have too frequently been. By this resignation Dr. Thomas R. Glynn, Professor of Physic at the Liverpool University College, becomes senior physician. Dr. Caton is at present the only candidate for the vacant office.

THE VICTORIA UNIVERSITY.

The election of Mr. W. Mitchell Banks as the representative of the Victoria University on the Medical Council has given general satisfaction here. Mr. Banks is well known as one who is deeply interested in all that relates to medical education, in which he has had considerable experience. He is essentially a practical man, and will make a valuable addition to the Council.

FALSE CHARGES AGAINST MEDICAL STUDENTS.

A report was published in the local papers that the medical students of the Liverpool School of Medicine had contributed to a disturbance at the Exhibition on the night of its closure. Mr. Paul, the Vice-Dean of the Medical Faculty, University College, made it his business to investigate the matter, and found that the statement was erroneous. Only three students were present during the evening, and they all left before the disorder commenced. Mr. Paul, in a letter which also appeared in the daily papers, alluded to the fact that the title of medical student is often assumed by young men who have no claim to it, and he describes the local medical students as being as well conducted as any other body of young men. Mr. Paul deserves the thanks of all for thus disproving a charge easily made and not always so easily disproved.

INFECTIOUS DISEASES IN LIVERPOOL.

A temporary hospital has been erected on ground adjoining the Netherfield-road Hospital for infectious diseases. The structure which has just been completed is admirably adapted for a fever hospital. It contains two commodious sick wards for six patients each, a room for nurses, and other accommodation. It is heated by two large ventilating stoves, and will be lighted by a new system of gas illumination. The hospital has been put up in a remarkably short time, and its erection has been superintended by Mr. Gerson Trier, manager of the English branch of the Doecker Hospital and Hut Factory. It has been officially visited by the city surveyor, Mr. Shelmerdine, and Mr. Thompson, clerk of works.

Liverpool, Nov. 16th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

GATESHEAD CHILDREN'S HOSPITAL.

AT a meeting of the Committee of the Gateshead Children's Hospital, held at the Town Hall on Friday last, it was determined to advertise for tenders, and to proceed with the erection of the building as soon as possible, so as to make it at the same time a Jubilee memorial. The hospital is to be constructed on the pavilion principle, on a site of two acres generously given by Lady Northbourne as a free gift to the hospital.

THE NEWCASTLE HOSPITAL SUNDAY FUND.

The collections for the hospitals were taken on the 24th and 25th of last month, and so far it would appear from the lists of subscriptions published that there has been an increased interest taken, as shown by the amounts as compared with last year's.

THE VOTING IN THE NORTH.

A considerable number of practitioners in the north received their voting papers on last Saturday, most of which are as promptly returned to the offices of the Medical Council. I am no "prophet," but still we are "clannish" in the north, and very few scattered votes will be given; fully 75 per cent. of the voters are in favour of three candidates.

NEWCASTLE NATURAL HISTORY SOCIETY.

A very extensive, valuable, and important collection of land shells, Helices, Bulimi, &c., has lately been presented to this museum by Mrs. Angas, Norland-square, Notting-hill, London, collected in various parts of the world by her late husband, Mr. George French Angas, who was a native of Newcastle, but chiefly resided abroad, and was well known as a naturalist and a scientist. Mr. Angas's sketches of the natural history and inhabitants of Australia and New

Zealand, of which at the time comparatively little was known, were exhibited many years ago at the Egyptian Hall, London, and were considered the "sensation" of the season. These sketches were afterwards published in imperial folio, under the title of "South Australia and the Zealanders Illustrated."

A MEDICAL CERTIFICATE OF NO USE.

At the North Shields police-court last week a landlady was charged with selling a bottle of spirits during prohibited hours. She pleaded in defence that the spirits were required for a case of emergency—namely, a confinement,—of which she could produce a doctor's certificate. She was severely cautioned, however, and fined. On the other hand, the kind-hearted landlady, although she has transgressed the laws of the land, may console herself with the thought that she has probably saved a life; for wherever alcoholic stimulants are required at a confinement, as a rule they are urgently wanted.

Newcastle-on-Tyne, Nov. 17th.

IRELAND.

(From our own Correspondent.)

SIR JOHN LENTAIGNE, C.B., D.L.

THIS gentleman died at an advanced age at his residence in Dublin, on Sunday last. Educated at Trinity College, Dublin, he graduated in Arts in 1825, and in medicine three years afterwards, and obtained the Fellowship of the Royal College of Surgeons in Ireland in 1884. His labours in relation with reformatory and industrial schools were well known and appreciated, and he fulfilled the duties of inspector of those institutions in Ireland in a thoroughly satisfactory manner. The deceased was a member of the Royal Irish Academy, ex-president of the Zoological Society of Ireland, member of the Board of Superintendence of Dublin Hospitals, a Justice of the Peace for the County of Dublin, and ex-president of the Statistical Society, &c.

THE PROPOSED CONJOINT SCHEME.

The College of Physicians, I am informed, have elected Mr. Greenwood Pim secretary to the Committee of Management for the conjoint scheme between the two Colleges. Considerable surprise has been expressed that the appointment was not conferred upon a medical man.

ACADEMY OF MEDICINE IN IRELAND.

The opening meeting of the Surgical Section of the Academy took place last week, when Sir William Stokes, President of the Royal College of Surgeons, delivered an address on "Finality in Surgery." A very interesting case was exhibited at the meeting by Mr. H. Gray Croly—that of a lad who by a fall last August lacerated the front of the knee-joint, and chipped off a piece of the cartilage of the internal condyle of the femur. The wound under antiseptic precautions healed satisfactorily, and the patient can now walk well.

CITY OF DUBLIN HOSPITAL.

On the 9th inst. Mr. Fitzgibbon amputated through the left thigh for disease of the knee-joint. The patient for upwards of a year had been under the care of an unqualified man, who, it is stated, applied plasters as the sole treatment. When operated on, the knee-joint was in a fearful state of disorganisation. On the same morning Mr. H. Gray Croly performed a perineal section on a patient who had passed several pieces of phosphatic stone, and who could not retain his urine. The bladder was opened by Allarton's median operation, for drainage purposes, and to give rest to the bladder. Exactly a fortnight since a similar operation was performed by Mr. Croly, and the patient since has been greatly relieved. Mr. Croly also removed a revolver bullet from the chest of a young man who had been shot about a year since, while attempting to rob a house. The bullet had entered the under part of the shoulder, and had penetrated the chest, as shown by the emphysema and congestion of the lung which had ensued. The bullet, however, could not at that time be found. The patient, having served a nine months' imprisonment, was admitted into hospital, when it was found that abscesses had formed at the front of the chest, and a piece of his coat had come out of one of these abscesses. It was thought by some that a hard body could be felt to the left of the sternum, and accordingly Mr. Croly made an exploratory incision, and found the bullet embedded in one of the ribs. The bullet, it may be mentioned, was of the ·380 size.

LISMORE UNION.

Dr. O'Farrell, Local Government Board inspector, on Wednesday held a sworn inquiry as to charges of neglect and ill-treatment of the inmates of the workhouse. The evidence generally showed that there was no foundation for the charges of inhumanity. But the medical officer believed the pauper attendants were unsatisfactory; he had frequently to report them; while the want of proper night nursing was the great drawback at the fever and infirmary hospitals.

Rabies has been of late extremely prevalent in Lurgan, Banbridge, and other places in the north of Ireland; and at a recent meeting of the Banbridge guardians it was determined to send a girl who had been bitten by a mad dog to Paris, to undergo treatment by M. Pasteur.

At a recent meeting of the Commissioners Dr. J. W. Patrick was unanimously appointed coroner for the county of the town of Carrickfergus, in the room of Dr. Taggart, deceased.

Dublin, Nov. 16th.

PARIS.

(From our own Correspondent.)

THE TRANSMISSION OF NERVOUS PHENOMENA.

Two curious communications have been made at the Society of Physiological Psychology, and at the Biological Society, by Dr. J. Babinski, *chef de clinique* at the Salpêtrière, on the transmission of certain nervous phenomena from one subject to another by means of the magnet. Dr. Babinski states that all possible precautions were taken to exclude simulation and suggestion. In the first series of experiments practised upon hypnotisable hystero-epileptics, hemianæsthesia was transferred from one patient to another, and other symptoms induced in the first case by suggestion—such as flaccid or spasmodic paralysis, crural and brachial monoplegia, hemiplegia, paraplegia, coxalgia, and mutism—were disposed of in the same way. The results of these experiments show that the two subjects have the same relationship to one another as regards *transfert* as the halves of one body. In a second series of cases spontaneous hysterical paralyses were passed on to the hypnotised subject, the condition of the original patient being, as a rule, improved. The following observations lead M. Babinski to hope that these practices may be used as a mode of treatment. A young girl with spontaneous mutism was placed *en rapport* with a hypnotisable subject, who forthwith became speechless. No improvement was noted at the first *séance*, but after twelve experiments the speechlessness was replaced by extinction of the voice. The induced mutism was removed on each occasion by suggestion. A patient of the hospital remained hemiplegic and contractured after an hysterical attack. Placed *en rapport* with one of the subjects, the hemiplegia diminished, and disappeared after four sittings. In different cases of organic disease similar phenomena were observed. The person hypnotised was placed in the somnambulic phase of artificial sleep with her back (as in the other cases) to the patient. An infantile cerebral hemiatrophy, characterised by spasmodic hemiplegia and athetosis, was then dealt with, the effect being a sharing of the symptoms between the two, the patient keeping her athetosis and handing over her spasmodic hemiplegia to her companion. Another woman, with right hemiplegia and aphasia due to softening, retained her own troubles, but transferred a numbness to the subject which ended in hemiplegia. In a third case of disseminated sclerosis with paresis of the four limbs, trembling, and the pathognomonic pronunciation, the scapegoat developed all the symptoms, but in an exaggerated degree. I shall not stop to examine M. Babinski's views on the subject, but will contrast with these experiments those of one of the most experienced workers in this field at the same hospital. M. Jules Voisin has tried on two of his patients the action of medicines *à distance*, and also of metals and magnets. A number of dark bottles containing different drugs were sealed and numbered, the contents not being otherwise

known. The subjects being placed in lethargy, somnambulism, or catalepsy, no medicinal effect could be induced. But when awake the production of the bottles was followed by hypnotism, with signs of nausea and vomiting. In this condition the mere mention of the name of any known drug was sufficient to give rise to a representation of its effects, manifestly due to suggestion and auto-suggestion. In the same manner, the subject being placed in one of the three higher phases of induced sleep, her state was in no way modified by the magnet. When awake, however, it produced an attack *if seen*.

THE TYPHOID BACILLUS.

In a recent number the *Gazette Hebdomadaire* gives an interesting account of a localised epidemic of typhoid fever manifesting itself in five members of the same family, and having its cause in the water used by the patients. The bacillus described by Eberth and Gaffky was found both in the water and in the blood removed from the spleen. MM. Dreyfus-Brisac and Widal point out that in a doubtful case the existence of typhoid may be easily determined by a harmless exploration and a simple laboratory experiment.

TANNIN IN TUBERCULOSIS.

MM. Raymond and Arthaud have made some comparative researches on the action of sulphide of carbon, iodoform, and tannic acid in tuberculous patients. Having found that when tannin had been administered to animals for a month, they were more refractory to the effects of the tubercular virus, it was used in more than fifty cases of human tuberculosis in doses of from two to four grammes daily. In less than a fortnight half the patients showed an increased weight, which continued during the treatment. In acute tuberculosis, both of the child and the adult, the symptoms amended, and the disease retrograded in some cases which had been looked on as hopeless.

Paris, Nov. 16th.

MONTREAL.

(From our own Correspondent.)

ENTERIC FEVER.

ENTERIC FEVER, which is endemic in Montreal, has this summer assumed an epidemic type. It generally begins to be more prevalent in October, but this year the increase in the number of cases began in August. This is shown by the number of cases admitted into the General Hospital. This institution is at present full, and the typhoid fever cases amount to 62 per cent. of the whole. There have never been so many cases of this disease in the hospital at one time before, and they come, not only from the city, but from the adjacent municipalities. To meet this increase in the number of patients, the governors of the hospital caused to be erected on the grounds at the rear of the building a hospital tent for the exclusive use of typhoid patients. This tent is oval in shape, forty feet in length by twenty in width, with a board floor four inches above the ground. To carry off any surface water a trench has been dug around the tent. By means of a stove the temperature inside the tent is kept between 60° and 70° F. It contains twelve beds, and is quite isolated, being supplied with separate nurses, orderlies, &c. At the rear of this tent a smaller one has been erected to serve for a kitchen. Although at first patients objected to being removed to the hospital tent, those who are there prefer it now to the wards. Notwithstanding the large number of cases of typhoid in and about the city, the mortality so far has been very low. The annual report of the hospital shows that collections from the city poor-boxes during the year amounted to $200.92, and that twelve churches took up collections in aid of the institution, the total sum collected being $497.54.

PLEURO-PNEUMONIA.

An attack of pleuro-pneumonia has unfortunately been doing considerable damage in the neighbourhood of the cattle quarantine at Levis, opposite Quebec. All available means have been taken to prevent its spread, and lately the Dominion Government purchased and slaughtered a number of suspected cattle belonging to farmers in the vicinity.

CANADIAN MEDICAL ASSOCIATION.

A very interesting meeting of this Association was held last month in Quebec, a large number of delegates from the different provinces being present. A number of valuable papers were read in the different sections, and a long discussion took place *in re* the quarantine stations below Quebec, in the course of which it was announced that the Government had decided not to appoint a port physician at Montreal, as they considered they had a sufficient establishment at Rimouski, Grosse Ile, and Quebec. The Government have, however, lately made some necessary improvements in the way in which these stations are managed.

The stipendiary magistrate has rendered judgment in the case of the Inland Revenue Department, *versus* a firm of coffee and spice manufacturers here. The court imposed a fine of $10 and costs, holding that the compound of coffee sold should have had the word "mixture" stamped on the packages.

A large new school building has just been completed by the Protestant Board of School Commissioners. It is 60 ft. frontage by 90 ft. deep, two and a half storeys high, and will accommodate over 600 children. It has been constructed with due regard to the latest advances in ventilation and hygiene generally, and cost upwards of $40,000.

Montreal has just commenced the plan of cremating all the garbage collected by the scavengers. From 170 to 250 cartloads are cremated every night. The work takes about six hours each night, and it is surprising how little of an offensive nature there is about the process.

Dr. R. P. Howard of Montreal, having resigned the vice-presidency of the International Medical Congress to be held in Washington, D.C., next year Dr. J. A. Grant of Ottawa has been appointed in his place.

Montreal, Sept. 30th.

Obituary.

FREDERIC JOHN FARRE, M.D., F.R.C.P.

BY the death of Dr. Frederic Farre, the Royal College of Physicians has lost one of its oldest Fellows and most honoured officers; for although at one time he was in active practice as a hospital physician, he had spent a large portion of his life in connexion with the College, and it is in this connexion that he will be chiefly remembered, as doubtless he himself would wish to be. He was the second son of the late John Richard Farre, M.D., who died in 1862 at the age of eighty-seven, having been for nearly fifty years physician to the Royal London Ophthalmic Hospital, of which he was one of the founders. Another son, perhaps better known to the profession, is Dr. Arthur Farre, who survives his brother Frederic. Frederic Farre was born in London on December 16th, 1804, and was therefore in his eighty-second year at the time of his death. He was educated at the Charterhouse, where he was Gold Medalist in 1821, and Captain of the School in 1822. He obtained a Foundation Scholarship at St. John's College, Cambridge, and sustained the reputation of that College by being classed a wrangler in the Mathematical Tripos. Having taken the B.A. degree, he chose medicine as a profession, and entered as a student at St. Bartholomew's Hospital. In 1830 he proceeded to the degree of M.A. at Cambridge, and in 1837 obtained that of Doctor of Medicine. In 1831 he was appointed Lecturer on Botany at St. Bartholomew's Hospital, and subsequently on Materia Medica. In 1834 he was elected Assistant Physician to the Royal London Ophthalmic Hospital, and also to St. Bartholomew's Hospital, where he succeeded in due course to the full Physiciancy. On retiring from St. Bartholomew's he was elected a Governor of that institution. Dr. Farre was also Physician to the Charterhouse, and Medical Officer to the Rock Life Office.

His connexion with the Royal College of Physicians dates back to 1838, when he was elected to the Fellowship. He held the office of Censor in the years 1841, 1842, and 1852; that of Lecturer on Materia Medica, from 1843 to 1845; of Councillor, from 1846 to 1848, and 1866 to 1867; of Examiner, in 1861 and 1862, and in 1866 and 1867; of Treasurer, from 1868 to 1883; and of Vice-President in 1885. Thus during a period of nearly half a century Dr. Farre took a prominent and active part in the affairs of the College, and especially during his term of office as treasurer he was indefatigable in guarding its interests and promoting its welfare. As a testimony of his attachment to the College, it may be remembered that

shortly before his resignation of the office of treasurer he presented the College with a manuscript history of the institution, which he had spared no pains to render full and exact. He was most punctual in the discharge of his duties, and his familiar presence and voice will be missed from the comitia meetings, which he never failed to attend. When last year he was nominated by the president to serve as one of the vice-presidents of the year, it was generally felt that no Fellow had a better claim to such a distinction.

Dr. Farre was editor of the first British Pharmacopœia, and of Pereira's Manual of Materia Medica. He also served as examiner in materia medica to the University of London. It is some time since he retired from professional practice, which he had carried on with much success when he resided in Montague-street, Russell-square. He married a daughter of the late R. Lewis, Esq., who survives him, as do also his two daughters, the eldest of whom is married to the Rev. Henry Spencer of Oxford. For the past five years or so he resided at Elsham-road, Kensington, and it was here that about six weeks ago he contracted his fatal illness —pleurisy,—in the course of which he was attended by Sir W. Jenner, and Drs. Brunton, Rayner, and Butcher. He died on the 9th inst., and was buried on the 13th at Kensal Green, where his father's remains also lie.

M. PAUL BERT.

THE death of M. Paul Bert, who has fallen a victim to the climate of Tonquin, has been the chief topic of conversation during the last week in scientific and political circles. M. Paul Bert was born at Auxerre in 1833, and received his early education in the department of the Yonne. His first preference was for engineering, and he entered the College of Saint Barbe with a view to preparation for the École Polytechnique, but, changing his mind, he commenced the study of the law, and passed successfully the examinations for the licence. He was on the point of entering the magistracy when he decided that the application of the Code was not his real vocation, and once more modified his course of study. Becoming acquainted with Gratiolet, then Director of Practical Anatomy at the Museum, he turned all his attention to original investigation, and obtained the doctorate in Medicine in 1863, and the doctorate of Science three years later.

After teaching zoology for some time at the Faculty of Sciences of Bordeaux, M. Paul Bert definitively came to Paris, acting as Flourens' substitute at the Museum, and succeeding Claude Bernard at the Sorbonne. At the same time, during the last few years of the Empire, he made himself conspicuous in the political world by his uncompromising republicanism, and at the fall of the Napoleonic dynasty, he was rewarded by Gambetta with the Prefecture of the Nord. In 1871, elected deputy, he became remarkable for his constant opposition to the religious congregations, which eventually brought about the decrees of expulsion against the Jesuits, Dominicans, and other orders. In 1881, he was made Minister of Public Instruction, in Gambetta's famous *Grand Ministère*, falling with his chief after an ephemeral exercise of power.

After the death of Gambetta, M. Paul Bert found his political influence on the wane, and partially returned to his former pursuits, obtaining a vacant seat at the Academy of Sciences. At the beginning of the present year, the attention of the French Government being forcibly drawn to the very unsatisfactory state of things in Tonquin, it was decided to send out a Resident General, invested with special powers, with a view to thorough reorganisation. The choice of the Ministry fell upon M. Paul Bert, who had always been a supporter of the present French colonial policy, and he left Paris for the East last February. The disorder in all the branches of the administration was so great that it required all the energy of the Resident General to set things right, a task which was rendered all the more difficult by the want of cordiality between the civil and military officials. It was this task that he seemed to be on the point of accomplishing when his health, already undermined by the deadly nature of the climate, gave way, and he died of dysentery on the 11th inst.

As a Member of Parliament, M. Paul Bert was instrumental in bringing about the changes that have been made of late years in teaching and education. In medicine, although a doctor, he was not a practitioner, his ideas on the subject of treatment being often prejudiced by an exclusive experience of the physiological laboratory. It was thus that he took under his patronage the pseudo-sciences of metallo-therapy and dosimetry, and caused some amusement in the medical world by his ardent advocacy of hæmo-pulvine. As a man of science, he was an original worker and an accomplished populariser. He took an interest in everything, and rapidly assimilated all that he studied. But, as a matter of fact, this extreme versatility prevented him from making more than a beginning in whatever he undertook, whether in politics, science, law, or mathematics, and it may be added theology. A striking anecdote of his intrepidity as a *savant* is related. Some years ago he visited Havre while a severe epidemic of small-pox was raging in that port. Noticing on his return to Paris that the mortality was daily on the increase, he began to entertain doubts as to the efficacy of vaccination as a prophylactic, and resolved to solve the problem to his own satisfaction by experiments on his own person. He accordingly got himself vaccinated, and going a fortnight afterwards to the Charité Hospital he had himself inoculated with the virus of a man who was dying from the small-pox. No ill effects having resulted from this terrible experiment, M. Paul Bert was completely won over to the cause of vaccination, which throughout the remainder of his life had no warmer supporter. Of his numerous productions we may mention "La Greffe Animale" (1863), "Notes d'Anatomie et de Physiologie" (1867-79), "Recherches sur le Mouvement de la Sensitive" (1867-70), "Leçons sur la Physiologie comparée de la Respiration" (his best work), and "La Pression Barométrique" (1878).

ARTHUR WYNN WILLIAMS, M.D. ST. AND., M.R.C.S.

ON Monday, Nov. 15th, at Brooklyn, West Drayton, Middlesex, Dr. Wynn Williams, aged sixty-seven, formerly of 1, Montagu-square, London, and consulting physician to the Samaritan Free Hospital for Women and Children, passed away. The following brief details of his life will be of interest to the many friends who now grieve over their loss. Dr. Wynn Williams was born at Bangor in 1819, and was a descendant from an old Welsh family, being great-grandson to John Freke, surgeon to Queen Anne. He was educated at Shrewsbury School, and, early determining to enter the medical profession, he was articled to the late Dr. Clements of Shrewsbury, and commenced his professional career at St. Bartholomew's Hospital and the University of St. Andrews, where he graduated as Doctor of Medicine. He married in 1843 Elizabeth Anne, daughter of the late W. Limell, Esq., of Dublin, by whom he had nine children. Settling in Carnarvon, he soon obtained an extensive practice, and became physician to the Carnarvon and Anglesea Infirmary, being beloved by all around him, especially the poor, to whom he was ever kind. He left Carnarvon owing to his health, and came to London in the year 1859, and started as a physician in the West-end; he soon gained distinction, and was appointed Physician to the St. George's and James's Dispensary, after retiring from which he was appointed Physician Accoucheur to the Western General Dispensary, and then became Physician to the Samaritan Free Hospital for Diseases of Women and Children, which post he held for over twenty years, and was finally appointed Consulting Physician to the above hospital, which appointment he held at the time of his death. As he found his duties were becoming too heavy for him, he decided to leave London and reside in the country, where he might enjoy a few hours' recreation, as he was a passionate lover of horticultural pursuits. He came up to London for consultation only—this he did for exactly one year; but at length, owing to having sustained severe bereavements in the loss of his son and daughter, both within a few months of each other, his constitution began to give way, and in spite of the skilful attention of several of his professional brethren, he died on Monday last of a somewhat obscure disease.

He was the author of many treatises, notably on the use of Iodine as an Antiseptic, and Bromine as a Remedy for Cancer, which led to their very general adoption by the profession. He invented a new method for operation on ruptured perineum, also a special uterine stem. His friends are

scattered all over the world, and we are sure there is not one of them who will hear of the death of "poor Dr. Wynn" (as they used to call him in Wales) but will regret his sudden demise, and will sympathise with his widow and family in their sad bereavement. He leaves a son and also a son-in-law in the profession to mourn their loss.

Dr. Wynn Williams was a medical man of great ability, and a skilful physician and operator, especially in diseases of women. Being the possessor of a handsome face and a commanding presence, he was all the more capable, by his tact and powers in recognising disease, and his great success in treatment, to win the full confidence of his patients. These qualities made him eminently popular among both rich and poor, owing to their being accompanied by a heart truly kind and ready to help all those who came to him in sickness or distress.

ROBERT NAIRNE, M.D., F.R.C.P.

WE regret to record the death of Dr. Robert Nairne, the much-respected Commissioner in Lunacy, which occurred at his residence, Mossley, Beckenham, on Nov. 5th.

Dr. Nairne received his education at Edinburgh and at Trinity College, Cambridge, becoming M.D. of that University in 1832. In 1838 he was elected F.R.C.P. of London; in 1839 he was appointed Physician to St. George's Hospital, where he had previously studied, and to which institution he subsequently became senior physician and lecturer on Medicine. In 1857 he was made a Commissioner in Lunacy, which office he held till July, 1883, upwards of a quarter of a century, when, having judged it advisable to resign his office, Lord Shaftesbury (then Chairman of the Board) was pleased to appoint Dr. Reginald Southey, one of the physicians of St. Bartholomew's Hospital, to be a Commissioner in his place. Subsequently, Dr. Nairne was appointed by Lord Shaftesbury to be an honorary member of the Board of the Commissioners. He married in 1856 a daughter of John Gott, Esq., and has left a widow and four children to lament their loss. In person Dr. Nairne was tall and of commanding appearance. His classical features must have been well known to many passers-by in Whitehall, where he was ever constant to the office, unless engaged in the laborious duties of visiting asylums. Of rather reserved character, yet he was kindness itself to those in whom he took an interest. His politeness and polished address both to superintendents and patients were points which might well be copied by any official holding a Government appointment. Dr. Nairne was a great stickler for etiquette, both in his relations to those whose asylums he was bound to inspect, and also on the Commissioners' Board, where naturally his indefatigable labours and length of service rendered him an influential and experienced adviser.

About a year ago Dr. Nairne was knocked down by a cab, and it is quite possible that the shock which he then sustained may have indirectly led to the fatal result which we here regret to record. By his death the profession and the public sustain a great loss.

JOHN GRIGOR, M.D.

A MAN of distinctly prominent mark has passed away from the north of Scotland in Dr. Grigor, who died at his residence, Larkfield, Nairn, on Monday, the 18th ult. He had had a severe attack of hepatic congestion accompanied with profuse hæmatemesis and melæna in November of last year, and though he made a fair recovery he was never quite himself again. During the summer he suffered from successive small boils about the face and from much breathlessness on exertion. Some three weeks before his death a small boil on the upper lip developed rapidly into a facial carbuncle, involving the lip and a considerable portion of the left cheek. The carbuncle was attended with severe pain and depression, which, acting on a constitution already enfeebled, gradually brought about the end. He was skilfully treated by Dr. Cruickshank, reinforced in consultation by Professor Ogston of Aberdeen, Dr. Macnee of Inverness, and Dr. Cameron of Nairn, but without avail.

The son of an Elgin solicitor, Dr. Grigor was educated at the Academy there till he entered on medical study at Aberdeen and Edinburgh Universities, taking the Licentiateship, and later the Fellowship, of the College of Surgeons at the latter school, and the degree of Doctor in Medicine at the former. He began his professional career in 1835 by serving as surgeon in Indian and Chinese waters; then, in some two years' time, he settled in Nairn in general practice, and soon earned a high reputation as a sound and successful practitioner. About thirty years ago he decided on making Rome the sphere of his labours, partly induced by his fondness for the artistic society and the historical associations of the place. There, again, he rapidly gained the esteem of the Anglo-American community as a skilful medical adviser and genial friend, till advancing years counselled his retirement from active professional life, and in 1881 he returned to Nairn. Of that town he was the Mæcenas and a great deal more heading every movement for its moral, intellectual, and social development, and munificently promoting at his own expense institutions of his special devising and founding. It is to him that Nairn owes her hospital as it now stands, her museum, her public swimming-baths, her public hall, her marine hotel, and many similar undertakings for the benefit of the town and district; while the wise and kindly spirit that animated him throughout life is perpetuated by his bequests. Among these amounting to about £12,000—are £2000 to the poor of Nairn; £2000 to the Nairn Academy, with the addition of £1500 for bursaries; £1000 for an Edinburgh University medical bursary, and £1000 for an Aberdeen University medical bursary, both to be called after the name of their founder; with a number of smaller sums for local charities and interests.

Dr. Grigor was a type of the northern practitioner; robust in body and mind, hearty in address, and hospitable to all well-accredited comers; with an intellect clear yet not cold, and solid yet not hard. He had many friends among former patients and among professional brethren, such as the late Sir J. Y. Simpson, Dr. Stewart, and Dr. Arthur Mitchell, all of whom were bound to him not only as an able and energetic physician, but as sharing kindred tastes in archæology and art. His memory will long be cherished with affection and gratitude in the north, as well as in Italy and Rome, where many a meritorious painter and sculptor owes to him life and health and substantial aid in his career.

THOMAS MIDDLETON, F.R.C.S.

MR. T. MIDDLETON, who recently passed away in his seventy-fourth year, during an attack of angina pectoris, was a descendant of Hugh Oldham, Bishop of Exeter, the founder of the Oldham Bluecoat School. He began the study of medicine some fifty-six years ago, when he was apprenticed for five years to Mr. John Boutflower of Greengate, Salford, who yet survives him. He then attended the Manchester Infirmary, and afterwards studied a few years in London and Paris. On his return to England he married and settled in Salford, where he practised for a quarter of a century, until failing health caused him to retire to the clearer air of Didsbury. Here he lived for the last twenty years, his unostentatious benevolence and other estimable qualities winning for him the respect and kindly regard of his neighbours and friends. One who knew him well describes him thus: "He was a quiet, reserved, kind-hearted practitioner, greatly respected by his patients, and able in the management of his cases; his practice was never large, but it was select. During the latter part of his life in Salford he interested himself very much in Church matters, and was a constant attendant at Christ Church upon the ministry of his intimate friend the late Canon Hugh Stowell. In his dealings with his brother practitioners he was always scrupulously professional, and he commanded the esteem not only of his patients, but of all who were acquainted with him." He will long and sorely be missed in Didsbury, where he was a generous contributor to good and charitable objects.

CHARGES FOR DISINFECTING IN BERLIN.—A public disinfecting station has been established by the Berlin civic authorities, where as far as possible high-pressure steam is employed. For such articles—leather goods, for example—as would be injured by this process, chemicals are substituted. The charge is 4*s.* for each cubic metre of space occupied in the disinfecting chamber, while the articles requiring chemical treatment are charged at the rate of 80 pfennings, or less than 1*d* each per hour of treatment.

Medical News.

UNIVERSITY OF LONDON.—The following is a list of the candidates who have passed the recent M.B. Examination:—

FIRST DIVISION.

Bright, Eustace Frederick, University College.
Burghard, Frédéric François, Guy's Hospital.
Carless, Albert, King's College.
Dobson, Leonard Charles Talbot, St. Bartholomew's Hospital.
Gabriel, Leonard Maurice, St. Bartholomew's Hospital.
Goodall, Edwin, Guy's Hospital.
Gow, William John, St. Bartholomew's Hospital.
Halstead, George Ezra, B.A., B.Sc., Guy's Hospital.
Johnson, Raymond, University College.
Kauffmann, Otto Jackson, Manchester, Owens College, and St. Mary's Hospital.
Permewan, William, University College.
Spencer, Walter George, St. Bartholomew's Hospital.
Trevelyan, Edmond Fairtel, St. Bartholomew's Hospital.
Voelcker, Arthur Francis, University College.
Washbourn, John Wychenford, Guy's Hospital.
Wild, Robert Briggs, Manchester and Owens College.
Young, Charles Wheeler Forrest, St. Bartholomew's Hospital.

SECOND DIVISION.

Alexander, Sidney Robert, Guy's Hospital.
Bahadhurji, Kalkhosro Nasarvanji, University College.
Burrell, Arthur William, London Hospital.
Carpenter, George Alfred, St. Thomas's Hospital.
Corbin, Eustace Rhodes St. Clair, University College.
Cox, Frederick Augustus, St. Mary's Hospital.
De Chazal, Edmond Lucien, University College.
Gardner, Henry Willoughby, St. Bartholomew's Hospital.
Gardiner, William Thomas, St. Bartholomew's Hospital.
Hart-Smith, Franke Chamberlain, University College.
Horrocks, William Henry, University College.
Hutton, John Stuart, St. Thomas's Hospital.
Jones, Samuel Cromwell, University College.
Muspratt, Charles Drummond, Guy's Hospital.
Prall, Samuel Esmond, Guy's Hospital.
Rivers, William Halse Rivers, St. Bartholomew's Hospital.
Smith, John Anderson, St. Bartholomew's Hospital.
Taylor, Alfred Ernest, Guy's Hospital.
Toogood, Frederick Sherman, University College.

CAMBRIDGE UNIVERSITY.—At the biennial election of members of the Council of the Senate, Professor Michael Foster, Sec. R.S., and Dr. Donald MacAlister, F.R.C.P., were elected to hold office for four years.

At a congregation held on the 12th inst. the degree of M.B. was conferred on the following gentlemen:—

Adam Rivers Steele Anderson, Caius; Sydney Arthur Monckton Copeman, Corpus; William George Holloway, Sydney.

COLLEGE OF PHYSICIANS IN IRELAND.—At the November examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—John Hornsey Casson, Louis Buggy, George Burkitt, Marcus Eustace, John Joliett, Maunton Meadows, Samson Hope Newland, Francis Glancy O'Donohoe, Alfred Ross, Francis Edward Thompson, Frank Thorpe, Arthur Thomas Wills.

MIDWIFERY.—Louis Buggy, Marcus Eustace, Francis Glancy O'Donohoe, Bartholomew O'Regan, Francis James Reid, Alfred Ross, Edward Johnson Williams.

The undermentioned have been admitted Members of the College:—

Joseph Duggan. | Gabriel O'C. Redmond.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners, held last week, the undermentioned were admitted Fellows of the College:

J. B. Fishbourne. | Thomas Donnelly.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery and received certificates to practise, on Nov. 11th:—

Cory, Guy Chamberlin, Disraeli-road, Putney.
Frese, Carl, Oxford-street, All Saints', Manchester.
Garrett, John Henry, Kineton, Warwick.
Glanville, Mark, M.R.C.S., Fulham-road, South Kensington.
Graham, John, Lower-place, Endsleigh-gardens.
Jarvis, William Charles, Southampton-street, Camberwell.
MacCallum, James Metcalfe, Carlton-street, Toronto, Canada.
Martland, Charles, M.R.C.S., Standish, Wigan.
Smith, Henry Sandford, Leamington-road Villas, Westbourne-park.
Walker, Benjamin, Eaglescliff, Yarm, Yorkshire.

BEQUEST.—The late Alderman Thomas Rose, whose funeral took place on the 15th inst., has bequeathed £25,000 to Manchester charities, including £10,000 to the Royal Infirmary, £5000 to Salford Hospital, £2000 to St. Mary's Hospital for Women, and £1000 each to the Eye Hospital, the Lock Hospital, and the Clinical Hospital.

ANTHRAX has appeared on two farms in Kent, one being near Maidstone and the other near Canterbury.

MOSCOW WORKMEN'S HOSPITAL.—The Moscow Town Council has decided to discontinue the subsidy it has hitherto paid towards the maintenance of the syphilitic department of the Moscow Workmen's Hospital.

RUSSIAN FEMALE PRACTITIONERS.—The Council of the Military Medical Academy in St. Petersburg has decided that a female qualified practitioner is entitled to proceed to the higher degree of doctor.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The Library of the College will be closed on Thursday and Friday, the 25th and 26th inst., for the purposes of the final examination for the Fellowship, for which 28 candidates have entered their names.

EDINBURGH HEALTH SOCIETY.—The seventh session of this Society was opened on the 13th inst., when Professor J. Cossar Ewart, in the Free Assembly Hall, delivered a lecture, on "The *Rôle* of Bacteria in Health and Disease," to a large audience.

SALFORD AND PENDLETON ROYAL HOSPITAL AND DISPENSARY.—At the fifty-ninth annual meeting of the trustees of this charity on the 17th inst. it was reported that the income of the institution during the past twelve months had been £4429, and that the expenditure had amounted to £4119.

PASS AND PLUCK IN PRUSSIA.—During the past *annus medicus* in Prussia, of 434 candidates for the State examination for practitioners, the "one portal" to the profession, 175 were rejected, while 259 passed, 16 of them with the distinction "very good." Of 220 candidates for the pharmaceutical licence, 190 passed, 30 being rejected.

REMISSION OF SENTENCE OF BANISHMENT.—Dr. Busch, formerly a surgeon of high rank in the Russian Fleet, who was sentenced four years since to the loss of civil rights and to banishment to Tomsk in Siberia, has, on account of his age, which is more than seventy years, been permitted to return to European Russia, on condition of his avoiding the capital.

MUNICIPAL HONOURS FOR MEDICAL MEN.—Mr. T. Vincent Jackson has been chosen as Mayor of Wolverhampton for the current year, and Mr. R. R. Daglish has been re-elected chief magistrate for the borough of New Romney, Kent. For the first time in its history, the Town Council of Darlington has two medical men among its members—viz., Dr. Drury and Mr. R. T. Manson.

THE EDINBURGH GRADUATES' CLUB.—A very pleasant meeting of the Club, at its quarterly dinner, took place at the Holborn Restaurant on Wednesday evening. Mr. R. B. Finlay, M.P., presided, and well sustained his reputation as a speaker. There were present as guests: Mr. Maunde Thompson, Mr. Edward Scott, Dr. Norman Moore, General Silver, Dr. Stokes, and others.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A meeting of the members of this Association was held on the 11th inst., when Dr. Kenyon read a paper in which he dealt with the difficulty of legal action for the abatement of insanitary conditions in an old church in which interment had taken place for a number of years. A lengthy discussion followed the reading of the paper.

FALLING OFF IN THE ENTRIES IN THE MADRID UNIVERSITY.—The number of first-year's men who have just matriculated in the medical faculty of the University of Madrid is only twenty. This is probably mainly due to some recent regulations enforcing a year of preparatory study before entering the medical school, and rendering the knowledge of two living foreign languages obligatory. The leading Spanish medical journal remarks that the great falling off in numbers "shows that fathers of families and students have recognised, what we have so frequently insisted upon, the small hope of a prosperous future which is offered by a medical career to the large majority of those who enter upon it."

BY the will of the late Mr. Thomas Pope the Leeds General Infirmary has benefited to the extent of £750, and the Leeds Public Infirmary has received £300.

DONATIONS TO HOSPITALS.—Mr. Joseph Shaw has given £100 to the Meath Hospital; Mr. Gervas Taylor, £50 to Adelaide Hospital; and Mr. Richard Carey, £200 to the Convalescent Home, Stillorgan.

HUGHES *v.* LANGMORE, ARMSTRONG, AND HUGHES.—This case, to which we shall probably have to refer in our next issue, was concluded on Thursday last, when Mr. Justice Manisty gave judgment for the defendants with costs.

HOME-MADE WINES.—The drinking of home-made wines made in glazed earthenware vessels has, according to the testimony of medical practitioners in Alcester, Wilts, resulted in the serious illness of several of their patients.

ENTERIC FEVER AT BARNSLEY. — Enteric fever having been seriously prevalent in the district of South Yorkshire, it has been decided, on the recommendation of Dr. Sadler, that the suspected sources of water-supply shall be closed at once.

BRITISH HOME FOR INCURABLES.—The report which was read on the 11th inst., at the twenty-fifth annual meeting and election of this charity, showed that there were at present 49 in-patients and 280 out-patients dependent on the funds of the Home, while during the year six in-patients and 14 out-patients had died. The year's receipts amounted to £17,549, and the expenditure, after deducting the amount credited to the general trust fund, left a balance of £69. The number of candidates for election was 95, and of these 11 were selected.

HOSPITAL SATURDAY FUND.—During the past week the council of this fund have issued their yearly reminder circular to the various friendly societies, vestries, clubs, and such departments of the various railway companies and the Woolwich Arsenal as have as yet made no return, intimating that all outstanding amounts should be forwarded to the central office, 41, Fleet-street, before the 30th inst., the date fixed for the close of the fund for the present year, in order that the same may be included in their thirteenth annual report. So far this year 2400 receipts have been issued.

PRESENTATIONS.—On the 11th inst., at a public meeting, Dr. Morgan (Treorky), was, on the occasion of his departure for Llandilo, presented with an illuminated address, five cases of surgical instruments, and a microscope, subscribed for by the inhabitants of the upper part of the Rhondda Valley.—Mr. Webb (Blakeney) has been presented with a silver inkstand, two silver candlesticks, and an illuminated address by the residents in the Forest of Dean district as a token of their regard and their regret at his departure. A travelling clock was also at the same time presented to Mrs. Webb.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BAILEY, J. JOHNSON, M.D., F.R.C.S.E., has been appointed Certifying Factory Surgeon for Marple District.

BREVOR, Sir HUGH, Bart., M.B., has been appointed Sambrooke Medical Registrar to King's College Hospital.

BUCK, LEWIN A., M.R.C.S., L.S.A., has been appointed Sambrooke Surgical Registrar to King's College Hospital.

COHEN, A., M.A., M.D., has been appointed Honorary Physician to the Jewish Convalescent Home, Lower Norwood, vice A. Asher, M.D., resigned.

CURREY, R. H., F.R.C.S.Ed., L.R.C.P.Ed., L.M., M.R.C.S., has been appointed House-Surgeon to the Liverpool Royal Infirmary.

DRINKWATER, CHARLES, M.R.C.S., L.S.A., has been appointed House-Surgeon to King's College Hospital.

EVANS, W., M.R.C.S., L.K.Q.C.P.I., has been appointed House-Physician to the Liverpool Royal Infirmary.

EWENS, G. F., M.B., has been appointed Physician's Assistant to King's College Hospital.

GIFFORD, G. T., M.R.C.S., L.S.A., has been appointed House-Surgeon to King's College Hospital.

KELSALL, C. J., M.R.C.S., L.R.C.P., has been appointed House-Surgeon to King's College Hospital.

LISTER, C. E., B.A.Cantab., L.K.Q.C.P.I., L.M., has been reappointed House-Surgeon to the Liverpool Royal Infirmary.

MANNING, T. T., M.B., has been appointed Ophthalmic Clinical Assistant to King's College Hospital.

MARIETTE, E. T. A., M.R.C.S., L.S.A., has been appointed Assistant House-Accoucheur to King's College Hospital.

O'MEARA, F. A., M.R.C.S., L.R.C.P., has been appointed Physician Accoucheur's Assistant to King's College Hospital.

PITT, G. N., M.D., M.R.C.P., has been appointed Assistant Demonstrator of Morbid Anatomy at Guy's Hospital.

SANDWELL, EDWARD, L.R.C.P.Ed., M.R.C.S., has been appointed Public Vaccinator to the Westminster Union, vice J. Rogers, M.D., resigned.

SMITH, FRED. J., M.B.Oxon., M.R.C.S., L.R.C.P.Lond., has been appointed Medical Registrar to the London Hospital, vice Dr. James Anderson, elected Assistant Physician.

THOMAS, W. THELWALL, L.R.C.P.Ed., M.R.C.S., has been appointed House-Surgeon to the Liverpool Royal Infirmary.

WARKE, C. L., L.K.Q.C.P.I., has been appointed House-Physician to the Liverpool Royal Infirmary.

WHEATLEY, J., M.R.C.S., L.S.A., has been appointed Assistant House-Physician to King's College Hospital.

Births, Marriages, and Deaths.

BIRTHS.

FRASER.—On the 9th inst., at Romford, Essex, the wife of James Alexander Fraser, M.R.C.S., L.R.C.P., of a daughter.

HARRIS.—On the 14th inst., at 149, Cold Harbour-lane, S.E., the wife of Henry Harris, M.R.C.S.E., of a son.

SMITH.—On the 10th inst., at Christ's Hospital, London, the wife of Alder Smith, M.B.Lond., F.R.C.S.E., of a daughter.

THEW.—On the 14th inst., at 12, Bondgate Without, Alnwick, the wife of Edwin P. Thew, M.B., C.M., of a son.

WALLER.—On the 21st ult., at Abbey-road, N.W., the wife of A. Waller, M.D., of a daughter.

WILLIAMS.—On the 16th inst., at Greenhill, Sherborne, Dorset, the wife of W. H. Williams, M.R.C.S., L.R.C.P.Lond., of a daughter.

MARRIAGES.

BEALE—FIELD.—On the 16th inst., at Lillington, Warwickshire, E. Clifford Beale, M.B.Cantab., of Upper Berkeley-street, W., to Mary Elizabeth, daughter of A. Sidney Field, Esq., of Blackdown-hill, Leamington.

CUMMING—SWAN.—On the 17th inst., at St. Chad's Church, Far Headingley, Leeds, Alex. S. Cumming, M.D., F.R.C.P.E., to Florence, daughter of the late Thomas Cole Swan, of Morpeth, Northumberland.

DALBY—SHEPPERSON.—On the 10th inst., at St. Andrew's, Harberton, South Devon, Augustus William Dalby, L.R.C.P.Ed., to Kathleen Mary, youngest daughter of Allin T. Shepperson, Esq., of Winsland, Harberton.

FIELD—SHIELDS.—On the 10th ult., at Sidney, Nebraska, Charles Hampden Field, M.D. (U.S.), Assistant Surgeon U.P.Ry.Co., late of King's (Lond.), to Henrietta, youngest daughter of the late John Shields, Esq., of Ottawa, Canada.

FITZ-HENRY—COOPER.—On the 18th inst., at St. Margaret's, Westminster, William G. Fitz-Henry, M.R.C.S.Eng., son of the late Capt. Fitz-Henry, to Isabella, second daughter of John Cooper, of Snaresbrook, South Sydenham-park, Forest-hill.

HARDWICKE—TILL.—On the 10th inst., at the Parish Church, Wolstanton, Staffordshire, Richard Reece Hardwicke, L.R.C.P., M.R.C.S., to Marion Elizabeth, youngest daughter of Edwin Till, Esq., of Wolstanton, Staffordshire.

HILL—COMYN.—On Wednesday, the 10th inst., at St. Luke's, Westbourne-park, George William Hill, M.B., B.Sc.Lond., to Flora Hastings, daughter of Capt. David Robert Comyn, R.N.R., and late of the Ottoman Imperial Navy.

DEATHS.

BIDWELL.—On the 15th inst., at St. Leonards-on-Sea, Herbert Bidwell, M.R.C.S.Eng., L.R.C.P.Lond., youngest son of the late Charles Muriel Bidwell, of Ely, Cambridgeshire, aged 24.

FARRE.—On the 10th inst., at Elsham-road, W., Frederic John Farre, M.D., aged 82.

FENTON.—On the 2nd ult., at Sandy Point, Straits of Magellan, Thomas Fenton, M.D. (many years Medical Officer in charge of the Chilian Colony), aged 35.

M'DOUGALL.—On the 16th inst., at Winchester, the Right Rev. Bishop M'Dougall, Canon of Winchester and Archdeacon of the Isle of Wight, aged 64.

PHILLIPS.—At Jamaica (of congestion of the lungs), John Mortlock Phillips, M.D., Surgeon of H.M.S. *Goshawk*, aged 26.

SANKEY.—On the 10th inst., at Boreatton-park, Shrewsbury, Arthur Octavius Sankey, aged 34.

WILLIAMS.—On the 15th inst., at his residence, Brooklyn, West Drayton, Arthur Wynn Williams, M.D., late of Montagu-square, W., aged 67.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, November 22.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. John Lowe: A case of Sarcoma of Stomach and Pancreas extending from the site of the right kidney, which had been injured eleven years previously, and which was found to be obliterated.—Dr. Samuel West: On a case of Subacute Atrophy of Liver of probably Syphilitic Origin.

Tuesday, November 23.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. T. Dixon: Ricinus Communis (communicated by Dr. Lauder Brunton).—Mr. Langton and Mr. Bowlby: A case of Multiple Embolism of the Arteries of the Extremities followed by the Formation of Aneurysms, with remarks on the relations of Embolism to Aneurism.

Wednesday, November 24.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Mondays and Thursdays, 9.30 A.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 2 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Conversazione.

HUNTERIAN SOCIETY.—8 P.M. Dr. Stephen Mackenzie: On Pemphigus.—Dr. Herman: On Pessary Treatment.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Dr. Bedford Fenwick and others.—Dr. Francis Imlach: The Relations of Digestive Disorders with Uterine Disease. Council at 8 P.M.

Thursday, November 25.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, November 26.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Sir Henry Thompson: Six cases of Tumour removed from the Bladder during the last twelve months, with a brief *résumé* of their histories and results.—Mr. B. Pitts: Supra-pubic Cystotomy for Tumour two years after the removal of growth by the perineal operation.—Mr. B. Wainewright: A case of Vertical Fracture of the Head of the Radius, complicated by Fracture of the Coronoid Process of the Ulna, and possibly a Split between the Condyles of the Humerus.—Dr. Herringham: Two cases of Diphtheritic Paralysis. Living Specimens:—Dr. Hughes Bennett: A case of Severe and Long-continued Epileptic Attacks, with Mania; complete recovery after trephining the skull.—Dr. Savill: Multiple Peripheral Neuritis.—Dr. James Anderson: A case of Intra-cranial Murmur, with history of relapsing optic neuritis.—Mr. Mansell Moullin: Complete recovery from Gunshot Wound of Foot.

Saturday, November 27.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

A GLIMPSE OF THE PAST.

"Vaccination was little practised, and seldom at the hands of a medical man. Mothers who sought it for their children generally kept them till the Rev. Mr. Nichol of Traquair came over on the Saturday of the Communion. He made a point of arriving a few hours before the service began, bringing lymph and inserting it. It was long believed that phlebotomy twice a year was conducive to health; and in spring and autumn, Mr. Ballantyne, Dryhope (old 'Phawhope' he was called) came an hour earlier to church with his lancet. Other great bleeders afterwards were old Robert Hogg, Yarrow Fens, and Mr. Morton, from Ettrick Bridgend, who continued the practice even after their hands had got shaky. Mungo Park gave Mr. Morton his lancet when he last left for Africa, and he presented it to the Rev. John Gibson, who became minister for Kirkhope." —JAMES RUSSELL, D.D., *Reminiscences of Yarrow*. (1886.)

A Constant Subscriber (Middlesbro').—We have no information on the subject beyond that comprised in our advertising columns.

THE APOTHECARIES' SOCIETY AND THE CONJOINT BOARD.

To the Editor of THE LANCET.

SIR,—Will you kindly notice in THE LANCET that I do not wish the decision of the Royal Colleges of Physicians and Surgeons to in any way stop replies being sent me from Poor-law medical officers. Up to the present time all the answers have been in favour of the Apothecaries' Society forming part of the Conjoint Examining Board.

I am, Sir, yours truly,

London, Nov. 17th, 1886. J. WICKHAM BARNES.

Mr. Wm. Berry.—1. Yes.—2. Probably, Maclehose, or through any medical bookseller.

SUNDAY AT OUR POST-OFFICES.

MR. ELLIS LEVER writes to suggest that, in celebration of the jubilee of Her Majesty's reign, the performance of Sunday labour by the post-office *employés* throughout the provinces be discontinued. He thinks that a little consideration for these useful and industrious public servants, and a small personal sacrifice on the part of the public, would lead to the total abolition of Sunday labour at the post-office, excepting in the telegraph department, and even this would be reduced, as the inclination to send telegrams is very frequently occasioned by the receipt of business letters.

Mr. T. L. K. Davies.—Without a copy of the rules of the institution it is hardly possible to give an opinion of value on the matter mentioned.

Mr. F. Treves.—In an early number.

"ON THE TREATMENT OF SNEEZING, HAY FEVER, ASTHMA, &c., BY THE GALVANO-CAUTERY."

Mr. Lennox Browne, in a letter to us on the above subject, complains that Dr. De Havilland Hall, in our issue of the 13th inst., quotes Hack of Freiburg, but omits to state that in the *British Medical Journal* of June 21st, 1884, he (Mr. Browne) advocated, as the result of experience, the galvano-cautery for exactly the same symptoms as are described in the solitary case on which Dr. Hall bases his dicta regarding its value. Also that Dr. De Havilland Hall specially mentions having used Schech's *cautères*, which, Mr. Browne states, in no practical respect differ from those he exhibited at Manchester in August, 1877. Lastly, that Dr. Hall ignores the fact that more than ten years ago Mr. Browne published a formula for the preparation of the carbolised smelling salts recommended in the article referred to for use in coryza.

Mr. C. J. Stocker.—1. Catarrhal jaundice not infrequently affects several persons, especially children, in the same neighbourhood at the same time, and is then probably due to climatic causes.—2. It would be most unwise to give solid food in enteric fever, even if the abdominal symptoms are not severe.

Dr. Brookhouse.—1. We do not see any inconsistency in the admission of such a case under the rule quoted.—2. This is a purely legal question.

University College.—The fee mentioned does not seem excessive; but it would be better to agree with the executors than to go to law.

Bona Fides.—We fear the agreement is binding.

ENGLISH MEDICAL CLASSICISTS.

To the Editor of THE LANCET.

SIR,—Allow me to supplement your list of these worthies with the names, *inter alios*, of Gideon Harvey, M.D., whose book on the "Morbis Anglicus, or The Anatomy of Consumption," appeared in 1666; William Salmon, whose "Compleat System of Physick" appeared in 1686; and Daniel Turner, whose book, "De Morbis Cutaneis," appeared in 1714. This last was recommended to me many years ago by the late Mr. Startin, who highly prized it; and, if we except the terminology and the therapeutics—portions of which, however, are still retained in practice,—it does not appear to me that it has been so very much improved upon, as some of our jaw-breaking dermatologists of the present day would assert or imply. To these I would venture to add Mead on the Plague, 1720; Erasmus Darwin's Zoonomia, 1794; and Cheselden's Osteology (the date of whose publication I have mislaid). And should any of your readers be willing to adopt your suggestion, and bring out an edition of Sydenham's Treatise of the Gout, I would strongly advise him to incorporate with it Cheyne's Essay, 1720, and Cadogan's Dissertation, 1771. Were I such an editor, I would use as a motto for such a publication the well-known line of Horace—

"Vixere fortes ante Agamemnona multi,"

and, believing as I do that there is nothing new in either the technique or in the literature of our art, I would clinch this with the following forcible words from Ruskin:—"There are few thoughts likely to come across ordinary men which have not already been expressed by greater men in the best possible way; and it is a wiser, more generous, more noble thing to remember and point out the perfect words than to invent poorer ones wherewith to encumber temporarily the world."

I am, Sir, your obedient servant,

Cedars Club, West Kensington, W., Nov. 15th, 1886. WM. CURRAN.

CONCERNING PHARMACOPŒIAS.

THE *British and Colonial Druggist* of Nov. 13th has the following:—"France has 2000 medicines in its Pharmacopœia; Spain and Belgium, 1500; Russia, 1080; Greece and Switzerland, 1010; United States, 1010; Great Britain, 815; Sweden, 746; Denmark, 720; Holland, 665; Germany, 606; Austria, 580; Hungary and Roumania, 545; Norway, 530."

Mr. O. B. Shelswell.—The attention of the Colleges should be directed to the matter.

M.R.C.S., L.S.A.—What would graduates say to such a proposal?

A. E. B.—We have no information.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

To the Editor of THE LANCET.

SIR,—Some time ago you kindly inserted a letter in THE LANCET informing all old students of the Meath Hospital, no matter in what quarter of the globe they were, that I was about to publish a Medical History of the Meath Hospital, and intended to insert therein the names of all former students who would favour me with the following information—viz., full name, address, date of study, present and past medical appointments. Former students who are serving in the army, navy, civil, and colonial services are earnestly requested to attend to this notice, if they have not done so already. As the work will soon be published, former students omitting to send me the information required may be annoyed by finding their names left out.

I am, Sir, yours truly,

L. HEPENSTAL-ORMSBY, M.D., F.R.C.S.,
Surgeon to the Meath Hospital.

22, Merrion-square West, Dublin, Nov. 16th, 1886.

"TWENTY DOCTORS."

WHO that has suffered from the recurrent worries of long-standing gout or rheumatism, or has even witnessed their tyranny in others, could withhold his sympathetic attention from the narrative of one who during seventeen aching years fought an uphill battle with the forces of "rheumatic gout." Such a narrative is afforded us, wherein the author in a short paper describes in a free and humorous style, without prolixity and with good sense, and the intelligence of one who has carefully watched the tactics of his enemy, and has been abundantly primed with skilled opinion, the painful course of that battle, which is now for him no more than a memory. A good deal of shrewd advice is informally conveyed in this little pamphlet as to diet and other considerations which are now part of the routine regimen of the disease. The remarks on the value of exercise (which the author used in the form of tricycle-riding) in restoring freedom of movement where joints have been stiffened by chronic rheumatic changes are well put, and have been justified in this case, as in many others, by the happy effects of what some may think a heroic treatment. The little paper which bears the above curious h[illegible] is singularly free from the presumption of empiricism, and s[illegible]what a gouty man can do for his own comfort if he will consent [illegible] by the rule of his constitution.

Dr. Ingle (Cambridge).—Placenta prævia: Behm, "Zeits. f. Geburtsh. u. Gyn.," Band ix., Heft 2, S. 373. Lomer, "Amer. Jour. Obst.," Dec. 1881, p. 1233. Cæsarean section: Sänger and Leopold, recent numbers of the "Archiv für Gynäkologie."

Nemo.—The best text-books are mentioned in the article "On Books" contained in our Students' Number published in September last.

Dr. Mackay (Huelva).—The paper has been received.

CRUELTY TO CHILDREN IN THE STREETS OF LONDON.

To the Editor of THE LANCET.

SIR,—I would desire to draw public attention in the journal of the late lamented Dr. Wakley, the humanitarian medical journalist, who wielded his powerful pen for the good of his fellow-creatures, to the cruelty inflicted on children by wilful exposure to inclement weather—the cold and wet which now prevail—by lazy and intemperate men and women, who take them about the streets of this, the world's greatest, metropolis, and by playing on a concertina and singing excite the sympathy of the passers-by and residents on the spot for the baby in arms or children by the side, who, by the way, very often are not their own, but borrowed on payment for the purpose of begging. Ought not the Legislature to step in and put a stop to such gross cruelty—a cruelty which not infrequently produces disease, and is a direct cause of death? Begging generally is not permitted in the capitals and other cities of continental countries, and it is time it should be put a stop to in this country by prosecution of these idlers and punishment for the offence. It would be a good thing if the public were to abstain from giving alms to such persons, as thereby they put a premium not only on the cruelty, but likewise on idleness, not to speak of the intemperance to which such idleness leads. These people, after getting a certain bag of coppers, adjourn to a neighbouring public-house for the purpose of imbibing gin and other alcoholic beverages, instead of food for themselves and children. It is to be trusted that your contemporaries will take the matter up.

I am, Sir, yours truly,

London, Nov. 12th, 1886. JOHN LUCAS, M.D.

THE BOSTON COTTAGE HOSPITAL.

CERTAIN of the statements made use of by the speakers at the annual meeting of the subscribers of the above hospital on Oct. 8th have caused considerable indignation amongst some of the members of the medical profession in the town. It was injudicious for the secretary to say "that their present staff included the three best medical men in the town;" but such a statement should be looked upon as expressing the complete satisfaction which the governing body felt in those officers who attend the institution. We do not know what the circumstances were "which if they had been repeated would have damaged the reputation of the hospital," and cannot therefore say anything about this part of the speech made by Dr. Adam. But it was certainly unwise, as well as unkind, to say in a public meeting that there were "doctors and doctors," when the statement could only be applied to the disparagement of a brother practitioner. We are informed that several of the clubs in the town attended by one gentleman are anxious for him to be placed upon the working staff of the hospital. This is but natural; it shows their entire confidence in him, and their desire to continue under his care. But it appears to us that the subscribers of the hospital have the right to determine the question.

Mr. F. Raymond, F.R.C.V.S.—We do not think there was a breach of professional etiquette in the case, though it would perhaps have been better for the physician to have had the corroborative testimony of a veterinary surgeon.

Mr. J. P. Thomson.—We cannot extend our exchange list at present.

EXPENDITURE FOR MEDICAL AND SANITARY SERVICE IN RUSSIA.

MANY of the provincial governments in Russia have evinced of late years an increasing desire to attend to the health and sanitary condition of their respective populations. In the thirty-four provinces into which "provincial institutions," or local governments, have been introduced, the sum expended on medical and sanitary matters has gradually increased from £206,000 in 1871 to £850,000 in 1883. The sums expended for this purpose are about 25 per cent. greater than those expended on education; but it must be remembered that all the population are benefited by the sanitary service, while only children require instruction. In seventeen of these provinces the mortality has diminished; in eight it has remained stationary, while in seven it has increased. It is instructive to compare the sums expended for medical purposes in the provinces with and without local institutions. In the former class of provinces the sum expended per head varied in the different governments from 2*d.* to 9*d.*, while in the latter the maximum was 2*d.* and the minimum a farthing!

Hector is justi[fied] withdrawing from the club appointment, after reasonable [notice] seeing that he took it under misapprehension.

D.—A certai[n] per day during the session and travelling expenses.

ALBUMINURIA IN PREGNANCY.

To the Editor of THE LANCET.

SIR,—Whilst the controversy is going on as to the value of the induction of labour in cases of albuminuria in pregnancy I would wish to call the attention of the profession to the administration of small doses of iodine of potassium as an almost certain remedy. I can speak from practical experience, and would strongly urge its claims to be tried before induction of labour is attempted.

I am, Sir, yours faithfully,

Harrogate, Nov. 10th, 1886. THOS. BRITTON, M.D.

COCAINE ADDICTION.

DR. J. B. MATTISON, of 314, State-street, Brooklyn, New York, asks us to state that he will be obliged if any of our readers who may have met with a case of cocaine addiction would send him the fullest possible details.

LUNACY IN KENT.

THE returns relating to lunacy in the county of Kent, which have just been presented to the Court of General Sessions by the medical superintendents of the Barming and Chartham asylums, show a large increase in female insanity in the county. At the present time there are in the two asylums as many as 1225 females to 882 males.

Cutis Parasitici.—We have no recollection of the treatment having been recommended in our pages, though we believe it has been adopted by experienced practitioners, sometimes with success.

Mr. G. J. Williams and *D. P. S.*—Mrs. Worthington G. Smith has written a useful book on the subject, published by Hardwicke and Bogue.

Northumbrian.—The holder of a commission only is entitled to the affix.

A Glasgow Surgeon is referred to THE LANCET of last week.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Pugin Thornton, London; Dr. Hughlings-Jackson, London; Mr. T. Bryant, London; Dr. Hale White, London; Dr. Thorburn, Manchester; Dr. J. Rogers, London; Mr. W. Curran, London; Dr. Whitelegge, Nottingham; Mr. J. F. Gant, London; Prof. Humphry, Cambridge; Dr. Britton, Halifax; Mr. Chesshire, Birmingham; Mrs. King, Upper Clapton; Dr. Mattison, Brooklyn; Mr. W. Fowler, London; Mr. W. Jago, Brighton; Dr. Quinlan, Dublin; Dr. Dolan, Halifax; Dr. John Lucas, London; Dr. F. Dale, Scarborough; Mr. Lever, Manchester; Mr. W. H. Pearce, Bromley; Mr. Sheiswell, London; Mr. Lennox Browne, London; Rev. Arthur Robins, Windermere; Dr. Arthur Farre, London; Dr. Downes, Tiverton; Dr. Collie, London; Mr. W. Gem, London; Mr. W. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

A Lecture
ON
DISLOCATION OF THE HIP.

Delivered in the Cambridge Medical School,

BY G. M. HUMPHRY, M.D., F.R.S.,
PROFESSOR OF SURGERY.

GENTLEMEN,—Here are two specimens of dislocated hip which we have recently had the opportunity of examining, and which will be placed in the Pathological Museum.

The first occurred in the practice of Mr. Balding of Royston, who was good enough to present it, and it has been dissected by Dr. Anningson. A boy aged thirteen was riding on the back of a horse drawing an empty cart. He lost control of the horse, and, so far as could be ascertained, fell astride the shaft to the left, with his *right* lower limb between the shaft and the horse. Dislocation of the right femur on to the dorsum of the ilium was recognised by the shortening of the limb, the position of the thigh across the lower part of the opposite thigh, the prominence caused by the head of the bone in the gluteal region, the fixity of the limb, and the intense pain caused by attempts to move it. Under chloroform reduction was soon effected by manipulation. The lad was suffering at the same time from bleeding from the right ear and the nose, and though he soon recovered from the effects of the chloroform, he became unconscious, convulsed, and died in two days. Fracture was found through the base of the skull. There was much extravasated blood beneath the gluteus. The gemellus inferior was torn from its attachment to the ischium. The obturator internus and quadratus femoris were lacerated, and the obturator externus was also lacerated and bruised. There was a valvular rent in the under and back part of the capsule, commencing just behind the pubo-femoral ligament, midway between the acetabular and the femoral attachments, as a single tear which divided and extended upwards and backwards to the tuber ischii, and upwards and forwards to the trochanter near the attachment of the obturator externus; or it might be described as a tri-radiate rent, the rays diverging from the apex of the valve, which was situate opposite the lower part of the tuber ischii. There is no fracture and no injury of the cotyloid ligament. The round ligament has been torn through obliquely, one part remaining attached to the femur and the other to the ischium. The ilio-femoral ligament was intact.

The second specimen is from a lad aged thirteen, who was admitted into Addenbrooke's Hospital, on July 30th, in a state of profound collapse, having been run over by a heavy cart a short time previously, sustaining serious injuries to the chest and abdomen, as well as a dislocation backwards of the left hip, the symptoms of which were as usual. He died in three hours, no attempt having been made to reduce the dislocation. The hip has been dissected by Mr. Francis. The displaced head of the bone was situated below the level of the pyriformis and obturator internus muscle on a level with the upper part of the tuber ischii, the sciatic nerve being pressed backwards between it and the tuber. The pyriformis and gluteus maximus and medius are intact. Some fibres of the middle part of the gluteus minimus are torn. The upper gemellus is much torn at its middle, and the lower gemellus is torn nearly through. The fibres of the internal obturator are slightly torn within the pelvis about an inch from the small sacro-sciatic notch. The quadratus femoris is torn quite across at the middle, and the external obturator is also torn across at a little distance from its tendon. Some of the superficial fibres of the pectineus are torn near the attachment to the os pubis. The three adductors, the gracilis, the ilio-psoas, and the tensor vaginæ femoris, are intact. There is a large valvular rent in the capsule, commencing at the pubo-femoral ligament as a single tear, about midway between the acetabular and the femoral attachments, and diverging into two, one running backwards and inwards towards the upper part of the ischial region of the acetabulum, the other backwards and outwards towards the femur near the attachment of the obturator externus. These enclose between them an angular or valvular portion of the capsule, which was reduced to shreds at its extremity. The round ligament has been torn from the dimple of the femur, and has carried with it a scale of the bone and a thin film of the cartilage. The ilio-femoral ligament is intact and quite lax in the dislocated position of the bone; but there are some small rents in the under part of the capsule near the thigh-bone, between the ilio-femoral and the pubo-femoral ligaments. The bone was easily replaced in the acetabulum by the ordinary method of manipulation.

A third example of backward dislocation of the hip which I have here—a dried specimen from the museum—is from a strong well-made man, aged thirty-four, brought to Addenbrooke's Hospital, many years ago, having been knocked down by a railway bank, which he was excavating, falling upon him. There was dislocation of the left femur backwards, which was reduced by the method then usually adopted—viz., traction across the opposite thigh, accompanied by slight inversion of the limb, with difficulty, the man being in a much depressed condition, and he had received injuries to the abdominal viscera, of which he died three days afterwards. On dissection I found that the head of the bone had occupied a position behind the acetabulum near the upper part of the great sciatic notch, in a cavity formed in the gluteus maximus by laceration of its fibres. The pyriformis was partly torn. The gemelli were both much torn, and the tendons of the obturator internus were torn from the muscle and hanging from the great trochanter. The quadratus femoris and obturator externus were intact, as were also the muscles in front of the hip. There is a great vertical rent along the back of the capsule nearer to its femoral than to its acetabular attachment, extending from the pubo-femoral ligament to the level of the fore part of the great trochanter, and there is a transverse rent under the position of the gemellus inferior running from the vertical rent to the cotyloid ligament. The ligamentum teres is torn through near its attachment to the femur. There is a fracture of the pelvis traversing the bottom of the acetabulum.

I think it is certain that, in each of these three cases, the head of the thigh-bone passed out of the acetabulum, not at the notch where the capsular ligament is weakest and the resistance to its escape is least, but further back, opposite the tuber ischii, at the part where the rent in the capsule radiates in three directions, and where, accordingly, the first strain upon the capsule must have been greatest. In the first and second cases this was just below the level of the obturator internus and the gemelli. In the third case it must have been rather higher—i.e., beneath the obturator internus, the tendons of which were torn away from the muscle by the force of the head of the bone thrust out beneath it. All three cases were, in short, examples of direct dislocation, and in none of them was the cotyloid ligament or the margin of the acetabulum injured. It has lately been maintained, upon insufficient grounds I think, that the dislocations of the hip backwards are always, or almost always, indirect, that the head of the bone escapes from the acetabulum close to the transverse ligament, and is then, if the limb be in an inverted position, carried backwards and, perhaps, upwards. Furthermore it is held that the accident occurs during the *abducted* position of the limb. I quite grant that the capsule is weakest and least supported by muscles in this situation, and that dislocation is easily caused here, in the dead body, by forcible abduction of the limb. But it is to be remembered that the capsule is weakest here because, in the living body, it is least liable to be strained in this direction. It may be observed with regard to some other joints, that the dislocations do not commonly take place in the direction in which they may be most easily produced. Notably is this so with the ankle. The configuration of the surfaces, which are wedge-shaped, the greater width being in front, and the disposition of the ligaments in that joint, are such as especially to resist the dislocation of the foot *backwards* and to permit its displacement *forwards*. Nevertheless, the former more commonly happens than the latter, because the direction of the forces which act upon the part, more especially when the foot is planted on the ground, are usually such as are calculated to drive the leg forwards upon the foot rather than backwards, so causing dislocation of the foot backwards. In the case of the hip-joint, the resistance of the acetabulum and the capsular ligament to displacement of the femur is greatest at the upper and back

part which is the part where strength is most required for the purpose of resisting the pressure and impulses in standing, walking, and running; and it is least at the under part because resistance to displacement in all ordinary positions and movements is there least required. The ligamentum teres comes into service when the thigh is flexed and adducted; the pubo-femoral ligament is put on the stretch when the thigh is abducted in any position of flexion or extension; and the strong ilio-femoral ligament is tight when the thigh is extended, its chief office being to prevent the rolling of the pelvis backwards, and so to give steadiness to the trunk, in the erect position. It may be here remarked that the construction of the several joints and of the skeletal framework generally is such as to withstand the *naturally* applied forces—the forces resulting from muscular contraction and the ordinary movements and impingements upon the ground—rather than the forces which are extraneous, unusual, and accidental. These last, indeed, could not be provided against without encumbering the frame with an amount of material which would involve, in too great a degree, the principle of lightness, and with it of ease and celerity of movement.

Now the natural and almost constant inclination of the thigh from the pelvis, in standing, lying, and in movements, is inwards—that is to say, the thigh is almost always adducted (whether in standing, walking, or running); and accordingly an external, driving, or wrenching force is far more likely to come upon it in that position than in the state of abduction. This is especially so when the limb is bent, for the tendency to adduction is then increased by the coordination of the adductors with the flexors; and it is in the bent position that the hip is commonly dislocated. In the fully erect posture the hip-joint may be said to be hyperextended, for it is then slightly bowed forwards, rendered convex in front, and the ilio-femoral, which is the strongest ligament in the body, being now on the stretch, bears the brunt of the weight, and of the forces that would increase that extension; and a driving force sufficient to overcome its resistance in that position is hardly ever applied, hence this ligament is very rarely torn. Indeed, the hip-joint is seldom subjected to much violence in any way in the extended position. It is in the more or less flexed state that injuries are generally sustained. In this position, as I have said, the thigh is not often *ab*ducted, and it is still less likely to be *ab*ducted and *in*verted, for *ab*duction is naturally and usually associated with *e*version, as adduction is commonly associated with inversion. A force applied to the limb or the pelvis, with the thigh so flexed—i.e., abducted and everted—could not throw the head of the bone behind the joint, but would throw it forwards into the obturator hole, or forwards and then upwards into the os pubis, and the pubo-femoral ligament would necessarily be ruptured. Indeed, a dislocation by *ab*duction in the flexed position, whether the limb be inverted or everted, must be attended by rupture of that ligament, which, be it observed, has not taken place in any of the specimens I have shown you. The probabilities, of course, are that a limb will be in a habitual or natural position when an accident occurs; and the position of flexion, *ad*duction, and *in*version is both a habitual position, and is the one in which the head of the femur is pressed against the part of the capsule (the under and back part); and this is the part which gave way in the specimens before you. A violent strain in this position, and in this direction, increasing the adduction and inversion and carrying the knee across the opposite thigh, would throw the head of the bone, through such a rent in the capsule as we see in each of these specimens, into the position it occupied, and would be likely to be productive of such laceration of muscles as we have found to have taken place in them. If in either of the more recent specimens the head of the bone be replaced in the acetabulum, it can easily be thrown out again when the femur is flexed, adducted, and inverted; whereas, if the femur be abducted, the dislocation is resisted by the pubo-femoral ligament, and the more the joint is flexed, the more obvious does this resistance become. In our third case, and in all the cases in which, as in it, the obturator internus is torn across, and also in those in which the head of the bone is placed under that muscle, the dislocation must have taken place beneath it, and must have been effected in the adducted position of the limb. I am of opinion, therefore, that the view formerly entertained is correct—namely, that the backward dislocations of the hip, whether accompanied by fracture of the edge of the acetabulum or not, are commonly direct, and produced by force applied to the limb in its flexed, adducted, and inverted position. And although it may be said that there is a natural tendency for the head of the femur to be displaced during abduction of the thigh, owing to the shallowness of the acetabulum and the weakness of the capsule at the under part of the joint, it must be added that there is not a tendency for forces to be so applied during that position as to drive the head of the bone backwards; and such displacement could scarcely be effected by muscular action. I find, in most of the described cases in which the manner of the accident could be ascertained and the position of the person and the limb is given, that the thigh is stated to have been adducted at the time of the dislocation. According to the direction of the force, the head of the femur will be driven to some extent upwards, with more or less laceration of the muscles and other tissues, the limitation of its course that way, and also backwards, being given chiefly by the untorn part of the capsule, and partly by the stretched muscles and other tissues. But it is not probable that in this or other dislocations of the hip, or in dislocations of other joints, further displacement, with the necessary attendant laceration, is effected by muscular action. I mean that the amount of displacement and of damage to the parts involved is proportionate to, and due to, the first shock of the injury, and that the immediately following, or subsequent, contraction of the surrounding muscles does not produce much, if any, additional displacement. The effect of muscular action in this respect in producing so-called *s*condary dislocations or displacements has, I think, been much overestimated, not only in this joint, but also in the shoulder. For instance, the subcoracoid dislocations of the shoulder are by some believed to be primarily subglenoid, the head of the humerus, according to that view, being first thrust through a rent in the lower part of the capsule and subsequently drawn up beneath the coracoid process. That this view is not correct is proved by the fact that in the ordinary subcoracoid dislocation the head of the humerus occupies a position beneath the subscapular muscle, between it and the inner surface of the scapula, a position into which it could scarcely be drawn by muscular action from the subglenoid region. The position of the limb in the dislocation of the hip we are considering—shortened, adducted, flexed, and inverted—is therefore that, or nearly that, in which, as I believe, it is when the accident occurs, and it is maintained by the head of the femur being placed behind and above the acetabulum, and held there by the pressure of the surrounding soft parts rather than by the tension of the ilio-femoral ligament, which, as seen in our specimens, may be quite lax. The points of attachment of that ligament—the fore part of the trochanter and the os pubis—may be rather approximated in the dislocated position. The flexion is maintained by the tension of the ilio-psoas muscle, which causes an increase in the lumbar arch if an attempt be made to straighten the limb.

Among the many and great improvements which the last half century has introduced into surgery is that of the treatment of dislocations, especially those of the hip, by manipulation under anæsthetics. I remember the case of a man, aged twenty-eight, in the Norwich Hospital under the care of the then well-known surgeons Dalrymple and Crosse, who was treated the day after he had incurred a backward dislocation of his hip by wrestling. Pulleys were applied, the limb being drawn across the opposite thigh, and force amounting from four hundred to four hundred and fifty pounds, as indicated by the dynamometer, was applied for two hours and a half, during which the man was bled to thirty ounces, and five or six grains of tartar emetic were given, with the view of producing faintness, before the dislocation was reduced. A large extravasation of blood took place into the buttock; but the patient ultimately did well, and recovered a useful limb. The following sudden case, at the same hospital, made a deep impression upon my youthful mind. A man aged twenty-six fell whilst carrying a sack of potatoes with his right leg doubled under him, and was brought to the hospital the next day. There were the ordinary symptoms of dislocation backwards, upon the dorsum of the ilium as it was considered. The usual means for reducing it were resorted to with, and without pulleys, for four hours, during which time thirty-six ounces of blood were taken from the arm, and twelve grains of tartarised antimony were given without inducing faintness, and with no good result. Each of the surgeons present tried in vain; and, finally, the attempts were desisted from. The position

of the bone it was thought was altered; but reduction of the dislocation could not be effected. Subsequently, abscesses formed and burst. The man was removed from the hospital, and died soon after. No post-mortem examination was made. These cases occurred before the blessings of anæsthetics were dreamt of. Under that influence the muscles would have been relaxed far more quickly, as well as more effectually, than by antimony and the lancet; and, with the methods of manipulation now adopted, it is probable that in both these cases reduction would have been easily effected by the able surgeons under whose care, with the appliances and knowledge of that time, the treatment was so severe and so prolonged, and in one of the cases so disastrous.

By the method of flexion, adduction, circumduction, abduction, and rotation in succession, under an anæsthetic, now commonly used, the following ends are attained. By flexion the head of the femur is carried down near to, or opposite to, the rent in the capsule; and, at the same time, the chief flexor of the hip—the ilio-psoas—is relaxed, and some of the extensors—the hamstring muscles—are relaxed at the knee, the relaxation thus produced in these muscles at the time more than compensating for the tension given to them by the flexion at the hip. By circumduction, abduction, and rotation outwards, the limb being at the same time lifted forwards by the hand under the knee, the head of the bone is brought to and slipped through the capsular rent into the acetabulum, which result is facilitated by the relaxation of the glutei and the external rotators. Moreover, by the tension given to the ilio-femoral ligament during abduction the trochanteric part of the femur is held firm and made to act as a fulcrum, while the head of the bone is carried under it, over the edge of the acetabulum, into the socket. Thus the reduction may, under an anæsthetic, often be effected with ease. But I must not lead you to suppose that this is invariably so. Difficulties which are not always easy to account for may occur, and may require patience and varied manipulation. The aperture in the capsule through which the head of the bone has been driven may be too small to admit of its easy return, or the head of the bone may be carried by the efforts at reduction to some other part at a distance from the opening in the capsule, or a torn muscular tendon may intervene and require modifications of the process. Moreover, the method is not altogether without risk to the integrity of the structures, and instances have been recorded in which the neck of the thigh-bone or the shaft of the bone has been broken in the forcible manipulatory efforts to reduce dislocations. Such events are, however, rare, especially in cases of recent dislocation, and are less likely to ensue from this method than from the severe procedures formerly adopted; and recorded cases show that a failure to effect reduction is less frequent under anæsthetics and manipulation than it used to be before those measures were resorted to. After the dislocation has been reduced there is no fear of its being reproduced while the limb is extended, whether it be abducted or adducted. In several instances the bone has been thrown out of the socket again during examination made to ascertain whether the dislocation was completely reduced. This is especially likely to occur when the dislocation has been left unreduced some weeks, not in the case of the hip only, but in dislocations generally, and most especially in those of the shoulder; the reason being—first, that the return of the bone into its socket is in such cases often not recognised by the usual snap or sound, and therefore more examination is needed to satisfy the surgeon respecting the reduction; and, secondly, that the parts have become adapted to, and more readily resume, the abnormal position. After the reduction of an old dislocation, it is therefore necessary to beware of this, and to use more care to prevent a return of the displacement than it is when the accident is of recent occurrence.

The points in connexion with the backward dislocations of the hip, to which I have wished more especially to direct your attention in this lecture, are—1. The position of the rent in the capsule through which the head of the bone escapes from the acetabulum—viz., at the lower and back part, behind the pubo-femoral ligament, therefore not at the lowest part, although the weakness of the capsule here may seem to predispose it to give way in this latter situation. 2. That the dislocation occurs commonly, not, as recently suggested, when the limb is abducted, but when the thigh is adducted, flexed, and inverted. 3. That the dislocation is not indirect, but direct, the head of the bone being driven through the rent in the capsule at the lower and back part of the joint, and then carried up to a variable extent by the force which caused the dislocation. 4. The *rationale* of the reduction by manipulation. 5. The liability to reproduction of the dislocation in cases which have remained unreduced for some weeks.

We must not allow ourselves to infer too much from experiments on the dead body, seeing that the conditions differ in so many respects from those in the living. In each of two strongly made male subjects I dislocated the left hip in the position I have referred to—viz., with the limb adducted, flexed, and inverted. This is not so easy as with the limb abducted and straight, because there is less leverage to work with, and it is less easy to fix the pelvis. However, with the aid of two men, I did it without any great difficulty. In both the bone was returned to the acetabulum before dissection.

In one, which was dissected by Mr. Francis, it was evident that the head of the femur had been driven [illegible] through the back of the joint under the obturator internus. A quadrilateral flap had been formed at this part of the capsule, the rent reaching from the trochanter, near the ilio-trochanteric ligament, to the back of the acetabular notch and extending along the edge of the circular ligament. The flap thus formed was found wedged into the joint between the head of the bone and the acetabular surface. The ligamentum teres was torn across near its acetabular attachment. The obturator internus was torn through within the pelvis; and its tendons, together with the trochanteric parts of both gemelli, which were torn nearly through, were wedged into the joint together with the flap of the capsule. The pyriformis was torn nearly through, and the obturator externus was torn through near its attachment to the pelvis. The upper edge of the quadratus femoris was slightly torn. The hinder edge of the gluteus minimus was much torn, and that of the medius slightly. The gluteus maximus was intact.

In the second, which was dissected by Dr. Griffith, the head of the femur had escaped from the joint rather lower down, passing through a rent in the capsule, which extended from the hinder margin of the notch, one-third of the circumference of the joint, near the cotyloid ligament, which was itself also partially detached from the edge of the acetabulum. The gluteus medius was slightly torn; but the gluteus minimus, the obturator internus, and the gemelli were intact. The obturator externus was torn from its pelvic attachment, and a portion was in the joint between the head of the femur and the acetabulum. The upper fibres of the quadratus femoris were also torn; the ligamentum teres was torn from the acetabulum, and remained attached to the head of the femur.

In one of these instances, therefore, it appears that the head of the bone passed in what may be called the favourite direction—in the interval between the obturator externus and the gemellus inferior,—which also took place in Cases 1 and 2 that I have given. In the other instance, as in my third case, the head of the bone passed out at a higher level under the tendon of the obturator internus.

It is noteworthy that in both these instances portions of the torn muscles, and in one the flap of the capsule, became entangled in the joint between the head of the bone and the acetabulum during the process of reduction; and I may remark that this was so in my second case, in which also the reduction was effected after death, and in which the trochanteric portion of the torn obturator externus was found in the joint. It is quite probable that a similar event may occur in the living subject, and account for some of the inconveniences which are now and then felt after reduction; and one can suppose that it is more likely to take place when reduction is effected by manipulation under an anæsthetic.

In both these instances the ligamentum teres was torn near its cotyloid attachment. This was so in Case 1, whereas in Case 3 it was severed near to the head of the femur, and in Case 2 it was torn out of the dimple in the head. In all dislocations of the hip this ligament is severed or detached. In a dislocation downwards, the traction upon it being in a direction the reverse of that which it is constructed to bear, it is, in common with other ligaments and tendons, likely to be detached or torn away from the bone; and I thought therefore that this might enable us to distinguish, after death, the downward dislocations from others. I found, however, by experiments upon the dead body that [illegible]

a reliable test; for, in some of the instances in which by forcible abduction I produced dislocation into the obturator hole, it was seen the ligament had not been torn out of the dimple, but had been severed at some point between its two attachments.

Lectures
ON
DISEASES OF THE LACRYMAL APPARATUS.

Delivered at the Royal College of Surgeons.

By HENRY POWER, F.R.C.S.

LECTURE III.—PART III.

IN now proceeding to give a short account of the mode of treatment that may with most advantage be adopted in cases of complete obstruction of the lacrymo-nasal passages, I place before you in the first instance a synopsis of the different plans that have been at various times devised and practised, from which it appears that they may be reduced to four principal methods—viz.:

1. Obliteration of the natural passages.
   - (1) By cauterisation.
     - *a.* With actual cautery.
     - *b.* With potential cautery.
   - (2) By excision of sac.
2. The formation of a new passage.
   - (1) Through os unguis.
3. Restoration of the natural passages.
   - *a.* By antiphlogistic means.
   - *b.* By injections.
     - α. Into conjunctival sac.
     - β. Through canaliculi.
     - γ. Through slit canaliculi.
     - δ. Through fistula or artificial opening into sac.
   - *c.* By compression.
   - *d.* By seton passed through duct.
   - *e.* By catheterism.
     - α. Downwards from the eye.
     - β. Upwards from the nose.
   - *f.* By incision of sac.
   - *g.* By excision of outer wall of sac.
   - *h.* By gradual dilatation (laminaria and other probes).
   - *i.* By rapid dilatation, slitting up canaliculus, and immediate introduction of large probes.
   - *j.* By lacrymotomes, after slitting up canaliculus.
4. Removal of the lacrymal gland, either wholly or in part.

The first method of treatment—that, namely, by obliteration of the natural passages—is of very ancient date; it is, in fact, described by Celsus, who lived, and probably practised, in Rome in the first years of the Christian era. He used the actual cautery, and the same proceeding was adopted by Paulus Ægineta 700 years later. It was again revived by Nannoni at Florence in 1748, and spread thence to Germany and France. It was commonly practised by Desmarres and by Jobert de Lamballe; and M. Blot, writing in 1865,[1] states that it was then in general use at that date in France. Reference need only here be made to the very clear accounts given by the two first-named writers, as their works are in everyone's hands. The alarm which this method excites in the patient's mind, as well as perhaps its apparent roughness and want of precision, cause it to be seldom practised in this country, though it is certainly effective, and in the few cases in which I have tried it the results have been very satisfactory.

Hirschberg[2] has recently recommended the use of his galvano-cautery for the cure of fistula of the lacrymal sac. In one case which had lasted for two years, and which might fairly be regarded as incurable, Paquelin's thermo-cautery led to an instant and permanent cure. The mode in which it was employed was that a metallic sound was introduced into the lacrymal duct in the ordinary manner from above, and a special burner, bent at right angles and ending in a pointed beak, was inserted into the capillary opening of the fistula until it touched the sound, when the current was passed.

Extirpation of the sac by means of the knife has been practised in some rebellious cases, and in modern times by such distinguished surgeons as Berlin and by v. Graefe. If determined upon, it is important to remember that the whole sac must be removed, or there is a risk that a cyst will form. The dissection should be conducted with care. Time should be given that the bleeding following the first cut should subside, and the sac should be separated as far as possible without injury from its surroundings. After it has been removed as completely as possible the interior of the naso-lacrymal duct should be well scraped with a Volkmann's spoon.

The chemical caustics that have been employed for the purpose of effecting complete obliteration of the sac are numerous. Amongst others are nitrate of silver, caustic potash, zinc chloride, antimony chloride, Vienna paste, and Canquoin's paste. The objection which naturally presents itself to the obliteration of the sac or to the complete artificial occlusion of the canaliculi is obvious. It is that it may naturally be expected to lead to permanent epiphora, and that it destroys the last chance of ultimate recovery. Passages lined with mucous membrane are notoriously difficult to close. The distal portion of the intestine, of the urethra or of the duct of a gland, into which a fistula opens, and which never transmits any of the normal contents of the tube, remains pervious for years, ready to resume its functions when the fistula is closed, and the course of the contents is no longer diverted from their natural channel: and it may well be, therefore, that in cases of epiphora, when the inflammatory trouble has subsided, to which the overflow of tears is due, the canal may once more become pervious, and the whole apparatus resume its functions. By obliteration of the canaliculus or of the sac this hope is abolished, and if the operation prove unsuccessful the patient is doomed for life to suffer from the disease for the cure of which he has applied to the surgeon. The reply that is given, however, by those who advocate this method of treatment is not unreasonable, and is to this effect: By abolishing the ducts which convey the tears to the nose, the reflux of unhealthy secretion, inspissated tears, and mucus through the puncta is also prevented; the conjunctiva is consequently freed from a permanent source of irritation. Moreover, after such obliteration, the lower part of the sac and the naso-lacrymal canal, no longer discharging their functions as ducts, become atrophied.

Considerations of space render it impossible that I should describe in detail the various methods of restoring the communication between the conjunctival sac and the nose. The plan proposed by J. L. Petit, the great French surgeon, who as a boy dissected so deftly that at the age of twelve he was made a prosector, was to plunge a bistoury into the sac through the skin below the tendon of the orbicularis; a channelled sound was forcibly pressed down the duct into the nose, after which a conical wax bougie was introduced. This plan was adopted by Lecat, Desault, and Boyer, in France, and I have often seen it practised by both the Guthries, who generally left a style in the duct with the head resting on the cheek. The results were not very satisfactory. The edges of the wound were inflamed, and much discharge took place from them. Mejean passed a needle armed with a thread through the canaliculus and down the duct, thus forming a kind of seton. Bianchi,[3] and after him Laforest and Allovel, endeavoured to clear the passage by attacking it from below; but the difficulties that present themselves to this operation from the varieties in the anatomical disposition of the parts are almost insuperable, and were strongly insisted on by Morgagni, who was opposed to this plan.

The method now commonly practised was introduced by Sir William Bowman, and has scarcely been modified since the time when his memoir on the subject appeared in the first volume of the Ophthalmic Hospital Reports. It consists essentially in passing a small probe grooved for the last half inch of its length into the canaliculus, and slitting it up along its whole length, converting the canaliculus into a groove or channel; room is thus afforded for the introduction of a large probe into the sac and duct, and all treatment by injections and by dilating instruments can be much more easily applied.

[1] Thèse de Paris, 1865. [2] Archives of Ophthalmology, 1879, p. 269. [3] De Dustibus Lacrymalibus Novis. Turin, 1728.

The introduction of a probe into the lacrymal sac and down the duct with normal canaliculi is often spoken of as a common and proper proceeding; in reality it is exceedingly difficult, and can only be accomplished by a very delicate and very practised hand, and not always by even the most skilful surgeon. The first part of the act is easy enough, and the recognition of the patency of the puncta and canaliculi requires no special skill; but to conduct the probe down the nasal duct without inflicting harm on the mucous membrane is a rare feat. The difficulty arises from the sudden change in direction which is required at the point where the canaliculi open into the sac. By stretching the lower lid outwards the canaliculus can be rendered nearly straight; the punctum is dilatable, and with a little management probes from one-twenty-fifth to one-tenth of an inch in thickness can be made to pass along the canaliculus till it strikes against the mucous membrane lining the groove of the os unguis, but its further progress is generally barred. A veritable *tour de maitre* has to be performed: the upper part of the instrument has to be brought upward and inwards till it is from 4 to 6 mm. to the inner side of the supra-orbital notch, and then gently pressed into the duct. It will be found in practice, however, that the point of the instrument becomes engaged in one of the folds of the mucous membrane; and if the finest probes be used no force can be exercised, since they can be felt to bend against the obstacle; whilst if one of the rather thicker, but still fine, probes be used, although more pressure can be exerted, yet it can be felt that the point is not making its way down the axis of the tube, but that it is impinging on the mucous membrane, and that there is imminent danger of perforating it and producing a false passage, a result which not unfrequently betrays itself by hæmorrhage and pain. There can be little doubt that considerable damage is often done by forcible and injudicious attempts to introduce fine probes, the mucous membrane being riddled with false passages, and the bone being in parts stripped of its periosteum, whilst the whole proceeding is productive not only of intense pain and discomfort to the patient, but of very little after-benefit to recompense him for the suffering he has undergone. I quite admit that in some cases the most satisfactory results follow the adoption of the plan suggested by Sir W. Bowman. I have no doubt that such instances as this might be quoted from the in-patient book of every ophthalmic hospital: F——, aged forty-four, eight years ago suffered from a lacrymal abscess on the right side. Has had repeated attacks of inflammation on this side since, with constant epiphora. Admitted into hospital on Nov. 14th. The lower punctum was slit up, a probe was passed, and a style retained for one day in the duct. This patient returned to the hospital one month afterwards quite well.

But is it not also true that there are many cases of failure to record—many cases in which, after the canaliculus has been slit up, and a probe, even a large probe, passed, or even when a style has been retained for many days, and the passage appears to be perfectly free, epiphora still continues? Do we not sometimes, instead of improving our patient, do him positive harm? I think I have seen force enough used to cause an ordinary probe to penetrate the membrane of the sac or duct. I think I have heard the os unguis or the maxillary bone crack. I am sure I have seen inflammation and caries follow injudicious attempts to introduce a probe. What has happened to me might, I imagine, happen to others. I remember an instructive case in this respect. A gentleman called on me complaining of epiphora. I found the eyelids, the teeth, and the refraction healthy. I was able to pass a fine probe into the sac along the canaliculus of the lower lid. No improvement resulted, and a few days afterwards I slit up the canaliculus and attempted to pass a Weber's probe down the duct. I was unable to find the bony canal, and in searching for it, and pressing the point of the probe here and there without, as I thought, undue violence, I have no doubt I perforated the mucous membrane and made a false passage. The result of this was that an abscess formed in the lower lid, which was opened and gave exit to some pus. The patient was not relieved of the epiphora by these proceedings, and I have no doubt felt, and felt truly, that he had gone through much suffering with very little advantage. It may be said I ought not to have made a false passage, and this is very true, but I would appeal to every ophthalmic surgeon whether it is not, in some instances, extremely difficult to strike the opening of the duct. An examination of some of the skulls in the College collection will show that the direction of the passage and the extent to which the forehead projects render it almost impossible to pass a probe in the usual direction. The failures, which we must admit not unfrequently occur, are probably sometimes due to want of patience both on the part of the surgeon and of the patient in the application of remedies; we expect to cure, and he expects to be cured of an affection that has been slowly developing, and which has produced profound structural changes in the course of a single, or at least of a few sittings. Many cases present themselves of the kind which I have here extracted from our in-patient book: "F——, aged thirty-one, admitted Oct. 20th. Three years ago, swelling at right inner canthus; two months ago, abscess at inner angle of eye, which slowly matured and burst one month ago. The opening healed, but tears have continued to run over the cheek since this time. The canaliculus was slit up, and a style was introduced. Nov. 14th: there is still trouble at the inner canthus; the canaliculus wound has closed. It was again slit up, and style passed. There was but little improvement on Nov. 30th, and the patient, declining to submit to further treatment, left the hospital." Here the disease was of three years' date. The walls of the sac and duct were probably greatly thickened and their cavity distended, and, although styles and probes could easily be introduced, a long course of injections and of remedies, both local and general, would probably have been required to effect a permanent and perfect cure.

When a style is used, care should be taken that it does not slip into the nasal duct or antrum, since in both instances it is extremely difficult or even impossible without a very serious operation to extract it. The accident is, to a certain extent, guarded against by the head or hook with which the upper part of the instrument is provided; but additional precaution should be taken by fastening a thin piece of silk or catgut to the neck, and fixing the thread on the forehead by a piece of sticking-plaster. I have seen one or two instances where the style has disappeared altogether—I have little doubt into the antrum, as the patient stated afterwards that he could feel it moving about when he ran or moved quickly; and I have once or twice myself lost the instrument in the duct, recovering it again with the greatest difficulty. I remember a case in which Mr. Guthrie (senior) laid open the sac and upper part of the duct, exposed the head of a style, and had to apply very considerable force to extract it. When removed, it was thickly coated with calcareous salts. Considerable diversity of practice exists, if I may judge from personal communication, in regard to retention of a style in the duct after it has been slit up. Some merely pass one and immediately withdraw it, directing the patient to return for a few days, and on each occasion separating the edges of the wound. Some keep the style in for a few days, and some for a much longer period. Each plan has some advantages and some very considerable disadvantages. If the style is retained for some weeks in the duct, there is no doubt that the channel is kept patent, which, it may be said, is the main object of the whole operation or proceeding; but, on the other hand, the upper opening into the sac becomes strangely misplaced towards the inner canthus, and although a probe may easily be passed down it the tears do not readily drain away from the conjunctival sac. Moreover, a kind of fungous granulation rises round the head of the style, and in former days, when leaden styles were used, the skin was often discoloured around it. If the style is immediately withdrawn, it is requisite that the patient should return for several consecutive days in order that the lips of the little wound should be separated, as they have a strong tendency to reunite. When the patient is unable to return, the plan suggested by Mr. Haynes Walton of snipping off a small portion of the posterior edge of the divided canaliculus may be practised with advantage.

The simple forms of obstruction should always be treated gently and tenderly at the outset. In many instances relief or a cure may be obtained by removal of carious teeth, and by the simple proceeding of injecting a little pure water into the sac by means of an Anel's syringe, the nozzle being introduced into the punctum lacrymale. Mr. Myrtle, the late house-surgeon of the Royal Westminster Ophthalmic Hospital, took infinite pains with a series of cases of obstruction, and effected in some cases great improvement and in others a permanent cure by this means, and has given me the notes of several patients where these results were obtained. Nevertheless, it must be admitted that the treat-

ment of lacrymal obstructions is, and must always remain, a difficult and unsatisfactory part of ophthalmic practice. The great variety in the proceedings that have been suggested by a multitude of practical and unpractical surgeons is sufficient evidence of the truth of this statement. I have adduced and exhibited drawings taken from the works of more than twenty authors, which, however, are for the most part only worthy of a passing notice, as they have passed into oblivion and are not likely to be resuscitated; but I may remark, in conclusion, that the larger my experience has been, the less disposed I am in trifling cases to resort immediately to the knife. Slight overflow of the tears is not a very great evil to endure, and conditions may be present which are absolutely incurable. Thus, in the first head which I brought to the College, the lacrymal organs of which have been beautifully dissected out by Mr. William Pearson, though there were no external marks of injury or any indication of disease, the nasal duct throughout its whole length was converted into a fibrous cord. What would incisions and the introduction of probes have effected here? In severe cases, especially where a fistula is present, the canaliculus should be slit up on Sir W. Bowman's plan, and a probe of moderate size passed down the duct. If this prove impracticable, the sac may be opened and the cause of the obstruction sought; but under these circumstances neither surgeon nor patient should be too sanguine of success, though this may sometimes be obtained by perseverance and skill on the part of the surgeon and by obedience and patience on the part of the patient.

ON

RHYTHMIC CONTRACTION OF THE PUPILS AND MUSCLES OF THE LIMBS WITH CHEYNE-STOKES RESPIRATION.

BY ALEX. ROBERTSON, M.D., F.F.P. & S., GLASGOW,
PHYSICIAN TO THE ROYAL INFIRMARY AND CITY PAROCHIAL ASYLUM, AND CONSULTING PHYSICIAN TO THE TOWN'S HOSPITAL, GLASGOW.

IT is well known that evanescent contractions and dilatations of the pupils may be induced by many other agents besides light and darkness. A sudden blow on the general surface of the body will cause a momentary widening; so sometimes will a powerful muscular effort. The same effect may result from violent mental emotion, and in a less transient form it may accompany dyspnœa, particularly if it has set in rapidly. These illustrations indicate how intimate and widespread are the connexions between the nerve-centres that control the movements of the iris and the great encephalic ganglia. With the exception of the last one, they are drawn from a state of health, but similar associations are present in many morbid conditions. My object in this paper is to direct attention to a marked instance of this relationship in the rhythmic movements of the pupils and even of the limbs, which in some cases accompany the peculiar modification of breathing that bears the name of two eminent physicians of this country, Drs. Cheyne and Stokes. Two patients have been under my care in both of whom this combination of symptoms existed in a typical form. I shall give a short account of their cases.

CASE 1.—T. S——, aged twenty-three, soldier, of drunken habits, was admitted into the Town's Hospital on Nov. 3rd, 1883, with a history of ague and suffering from rigor. On the night of his admission he became unconscious, and he was so next day about 12 o'clock, at the time of my visit. The respiration was then distinctly Cheyne-Stokes in its character. When I began to examine him both his arms and his legs were extended and rigid, but they did not continue in this condition, as they soon relaxed, though directly afterwards they again got stiff. I noticed that it was only when the breathing was fullest and most vigorous that the contractions were maintained, and that during the brief cessation of the respiration the muscles were soft and the limbs quite supple. These combined rhythmical movements continued during all the time of my examination of the patient—about twenty minutes. The state of the pupils also attracted my attention. When the breathing was full and laboured the pupils were distinctly dilated; as soon, however, as the descending process had fairly set in, pupillary contraction began, and it continued to progress *pari passu* with the descent of the respiration, until, when the latter temporarily ceased, they had become obviously but not minutely contracted. His pulse was 70, and regular; it was not observed to change with the alterations in the breathing, as has been noted in some cases. The temperature in the axilla was 102·6°, and he perspired profusely. The tâche cérébrale was well marked. There were no râles in the chest. At 6 P.M. the ascending and descending respiration was very typical, the interval of abeyance being longer than in the morning. With a view to test the strength of the morbid dilating action on the pupils, I exposed them to the bright light of a candle while the breathing was ascending, and found that, instead of contracting under light, their width continued to increase till the acme of the breathing was reached. On the other hand, during the descent of the breathing the contraction of the pupils went on even when the eyes were shaded. I watched these rhythmic movements during many successive cycles. At this visit the contractions and relaxations of the extremities, synchronous with the breathing, were still present, but were much more decided in the arms than in the legs, which did not altogether relax even during the pause of the respiration. He crunched his teeth when his limbs contracted. There was no retraction of the head. At 10 P.M. he was much worse, and the special phenomena had disappeared. He died the same night at 3 A.M. At the necropsy the cerebral pia mater was found to be injected everywhere, but particularly at the sides and the base. The chief lesions were two sanguineous effusions in the right hemisphere. The larger was about the size of a walnut, and was situated just external to the anterior extremity of the corpus striatum. The seat of the smaller, which was about half this size, was an inch and three-quarters from the anterior extremity of the right frontal lobe, near the longitudinal fissure. The heart weighed thirteen ounces and a half; there was no valvular disease, but there was hypertrophy, apparently concentric, of the left ventricle.

CASE 2.—M. A——, aged seventy-eight, was admitted into the Town's Hospital on Dec. 7th, 1883. Her friends stated that this her second attack of palsy on the right side set in three days previously. The day following its onset she became unconscious, and has continued so ever since. On admission, all the ordinary symptoms of right hemiplegia were well marked. Her breathing at first was quiet and regular, but on the 10th it became Cheyne-Stokes in character. At the same time the power of swallowing was greatly impaired. I extract the following entries in my note-book, chiefly respecting the pupils:—1 P.M. (10th): "The pupils gradually dilate during the ascending stage of the breathing, and contract when the respirations become shallower. These changes are best marked in the right pupil. The dilating pupils contract under strong light, unlike the case of T. S——." In the latter case the breathing was more typically ascending and descending than in the present one. 2.50 P.M.: The respiration was found to have become regular, but in about five minutes after this observation was made the previous rhythmic irregularity accompanied by the pupillary changes recurred. "The pupils become very small when the breathing gets feeble and dies away, and gradually dilate as it becomes deeper and more pronounced. While they are wide, light causes an immediate contraction. 7 P.M.: Cheyne-Stokes breathing and associated rhythmic movements of the pupils still present." 11th, 12 noon: I found her lying on her side breathing quietly and regularly, the respirations being 30 per minute, the pulse 100, hard, and the axillary temperature 100·2°. The pupils were wide, and responded feebly to light. I caused her to be turned on her back, and immediately the Cheyne-Stokes breathing and also the pupillary movements returned, though not in so marked a form as previously. She was again put on her side, but the rhythmic irregularities of respiration and pupils continued. Patient's condition now got gradually worse, and she died next day (12th) at 3 P.M. A post-mortem examination was not obtained.

Remarks.—Since these two cases occurred I have seen a number more in which the Cheyne-Stokes respiration was present, both in my own practice and that of medical friends whom I had spoken to about the associated pupillary movements. In only one, however, was there rhythmic contraction and dilatation of the pupils, and the symptom was not so well marked as in the cases I have here described. I had hoped to have met with others by this time, and that together they might have yielded some indication of the

special morbid condition in the brain on which this peculiar combination of symptoms is directly dependent; but I have been disappointed, and now put the above cases on record so that the attention of other observers may be directed to the subject. The first of the two has the additional interest, that the disposition to rhythmical contractions was not confined to the pupils, but also affected the muscles of the limbs. It was certainly very striking to notice, while the breathing was ascending to its acme, the limbs gradually become more and more rigid and the pupils more and more dilated; and, on the other hand, in its descent, the limbs slowly relaxed and the pupils steadily contracted.

GENERAL NEUROSES HAVING AN OPHTHALMIC ORIGIN.[1]

By H. BENDELACK HEWETSON,
OPHTHALMIC AND AURAL SURGEON, GENERAL INFIRMARY, LEEDS.

IT is now some years since I first observed symptoms, many and varied, occurring in neurotic persons who were also the subjects of uncorrected optically defective sight. In investigating more particularly the relationship between the various optical errors and sick headache, or simple headache, I was occasionally startled by the apparent direct relationship between the long uncorrected disorder (with all its immediate train of nervous disorders) and general conditions of ill-health which seemed to be the direct outcome of a thus already demoralised nervous system. It is now well established that many cases of migraine or sick headache are directly attributable to the reflected irritation of the brain (and thence the gastric functions and heart's action) from some uncorrected optical state, chiefly on the side of hypermetropia, and always in a neurotic subject. It is also well proven that many of these cases are entirely relieved from their periodic attacks by the use of properly selected glasses; or, having passed an age when the activity of the accommodation ceases more or less, and the eye becomes presbyopic, the severity of the headache or migraine becomes greatly modified. It is further well known that a patient the subject of hypermetropia is liable, according to varying circumstances, such as extent of defect and use of the eyes, to more or less constant "head pains," not necessarily associated with very obviously defective vision or aching eyes, but always peculiar in their position and character, and aggravated by close application of the sight. Although I have very fully published my observations some time ago on the relations between sick headache and optical defects, and utilised what was previously discovered as to the relation between headache (broadly defined as such) and hypermetropia, I had not felt my footing sufficiently to enable me to bring forward that which it is now my desire to show—viz., that the neuroses growing and arising from congenital optical error are more subtle in their nature, more varied in their distribution, and more demoralising to the right evolution of the nervous system than I was at first led to suppose.

The most common forms of headache associated with that optical error known as hypermetropia are—either simply a heaviness or pain over the brows (this may or may not be combined with general headache), or very frequently a tender place on the top of the head, making it particularly painful to dress the hair—such a pain as occurs after a lock of hair has been "slept on the wrong way," in common parlance; there is also frequently pain at the back of the head. All these pains may be present together, or they may exist singly, but they all occasionally occur in conjuction with severe neuralgia at the back of the neck. This I have frequently noticed, and where it occurred, whether associated with the other head pains or not, it, as well as they, soon disappeared with the systematic use of accurately adapted correcting glasses. This symptom of pain at the back of the head and neck is not one which has long been associated with optical defect, but I have now seen a sufficient number of cases to show without doubt that such may be safely regarded as one of the symptoms of (frequently latent) optical error, perfectly remediable by the use of glasses, and, when such, by glasses only.

Dr. Lauder Brunton writes me that he has seen several cases of neuralgia of the back of the neck cured by glasses. It would not appear to need demonstration that with symptoms so severe and depressing to the general nervous system as are the various forms of headache—vertigo, which is associated with astigmatism; vomiting; possibly, as I have noted, palpitation, or neurotic dyspepsia between the attacks of migraine—other conditions should arise as a sequel in many constitutions. One which I particularly wish to draw attention to is insomnia. This particular symptom I observed in one or two cases, the subjects of astigmatism. In one instance in particular, where the eyes had given much trouble during the examination period of an Oxford man's life, it was particularly remarked to me that after the astigmatic trouble was corrected by suitable glasses, *with an equal amount of work*, the insomnia disappeared and the whole physical and nervous state of the gentleman improved greatly. One object of my paper will be to show what an important factor these optical errors are in, as it were, moulding during childhood and early life the nervous and constitutional state of the individual. As a proof of this I will quote two cases, both in ladies of education and refinement, which seem to give us some sort of clue to the possible effects on the constitution of persons who conscientiously struggle through a severe scholastic career with important optical errors entirely uncorrected.

The first case was that of a lady aged twenty-two, whom some few years ago I found to be the subject of confirmed hypermetropic astigmatism. Her health was not good, but she particularly complained of headache and general feelings of malaise. I corrected the astigmatism after very patient testing, since here great nervousness made it a very trying process for myself as well as the patient. There were other symptoms such as would be ordinarily covered by the convenient but too easily accessible term hysteria, which showed itself in subjective pains at the back of the neck, tenderness of the spine, and frequently of the skin generally. There was no apparent lesion in any important organ, and she appeared to be the possessor of a greatly demoralised nervous system, which was easily overwrought, no matter what amount of moral pluck appeared to be put forth to resist an attack. After wearing the glasses for three years constantly her whole being seemed to change, so great was the relief. All headaches and difficulty in obtaining sleep disappeared, the appetite improved, and she became more companionable at home. But there was evidently with all this improvement a disordered state of the nervous system not yet removed, the tenderness of the spine remained more or less, and the health was still subject to variable and unaccountable fluctuations. I made up my mind that though the head pains had been so far recovered by the use of glasses, yet the long struggle in pain and toil of educational work had so far damaged the peripheral nerves that some other means of cure must be attempted. I may say that drugs had long since been given up as useless. It occurred to me that a course of medical rubbing would probably be productive of some good in the form usually called "massage." I accordingly sought and obtained a consultation with Dr. Fletcher Little at Ben Rhydding in the early part of last winter, and, although the weather was so severe, we decided that the patient should undergo this treatment under Dr. Little's supervision at Ben Rhydding, and I have greatly to thank that gentleman for assisting me to obtain the excellent result, for in two months she went home perfectly well, and I may also add she remains so.

I have in the second case received great encouragement from the treatment above adopted, but its expense necessitated an early abandonment of the massage, yet I have heard that the patient is much improved in general health.

I could multiply instances in which varying degrees of this kind of nervous demoralisation occurred; but generally there is either nerve-resisting power or neurotic recuperation sufficient to enable the individual to recover, if the sight be fully corrected, without having to resort to the massage treatment for the rest. I am perfectly convinced that until the sight had been corrected all such treatment as I have indicated would be useless. If carefully looked into, this appears to me to suggest some very important conclusions in relation to the community at large. I see children driven to do their work although suffering from defective sight, constant headache, and restless nights, which result

[1] Read before the meeting of the Yorkshire Branch of the British Medical Association held at Bradford.

in great exhaustion of the nervous system, disturbance of the various functions of the body, and a disinclination to innocent and beneficial child-play, all of which is with perfect ease set to rights by a correction of the optical defect which causes it. But supposing that a naturally nervous subject grows up under these conditions, the right evolution of some of the nervous system is undoubtedly endowed with morbid action, as well as the formation of the character disturbed. The causes are evident; the consequences, I believe, will be found in some of the neuroses which I have endeavoured thus imperfectly to describe. As the practical outcome of these observations, I trust it may not be considered a superfluous precaution to suggest that all children's sight should be tested by the ophthalmoscope before they commence their educational career.

Leeds.

FATAL CASE OF "MUSHROOM" POISONING.

BY H. HANDFORD, M.D., M.R.C.P.,
PHYSICIAN TO THE NOTTINGHAM GENERAL HOSPITAL.

E. W——, aged thirty-two, a fitter, gathered about a quarter of a pound of what proved to be Agaricus (Amanita) phalloides (Fries) on the afternoon of August 20th. On returning home he fried them in fat and ate them, about half an hour after taking his usual meal of tea and bread-and-butter at 7.30 P.M. (These apparently trivial details are mentioned for the following reasons. First, thorough cooking appears to weaken or destroy the poisonous active principle of many kinds of fungi. Secondly, it has been stated that in the closely allied Agaricus (Amanita) muscarius the action of water is necessary to produce the active principle muscarin, which does not exist preformed, and therefore cannot be extracted by alcohol. As no water was used in cooking, the time required for the production of muscarin by the action of the watery fluids of the stomach may account for the delay in the onset of symptoms. And thirdly, the presence of an undigested meal in the stomach may also partially account for the slow onset of symptoms.) While eating the "mushrooms" he gave *part of one* to his little daughter, aged three years and a half. He went to bed at 10 P.M., and slept well all night. He got up at 5 A.M. and complained of a weight and sense of constriction at the chest; he had pain in the bowels, and passed an ordinary motion. He went to work at 6 A.M., and between then and 8.30 vomited three times. At first he brought up the "mushrooms" very little changed, and afterwards a yellowish mucous fluid. He was purged several times. Sweating was profuse. His sight was not affected. He had some tea, but no solid food for breakfast, and worked on till 11 A.M. The vomiting and purging had continued, and he felt weak and faint, but was able to walk home after taking some brandy. The sweating continued, and in the afternoon his sight became dim, and he suffered from headache. He lay on a sofa all the afternoon, and, becoming worse, came to the General Hospital about 8 P.M. on Aug. 21st, and was admitted under my care.

On admission he complained of pain in the abdomen. His pulse was very small, and he was in a condition of collapse. He was given an emetic of sulphate of zinc, followed by mustard and warm water, and vomited freely. He then had an ounce and a half of compound senna mixture, with a small dose of tincture of opium to relieve pain, and three ounces of brandy. He passed a restless night, vomiting and being purged continuously, and I saw him for the first time at 11 A.M. on Aug. 22nd. He was then he was very exhausted. His voice was husky. Pupils equal, visit. The size, and reacting readily to light and accommo- its character. The skin was moist, but the sweating had ceased. and his legs only just perceptible at the wrist, and could tinue in this c[ondition]. The heart beats were weak, but regular, afterwards the 92 per minute; respiration 17 per minute, when the brea[th] He complained much of pain in the abdomen, contractions the left lumbar region, which was tender on sation of the [abdomen]. He lay on the right side, with his knees drawn quite suppl[ied] very drowsy. His temperature was 97°, though tinued duri[ng] hed of feeling hot and threw off the clothes. He bout t[en] d a small quantity of urine with his motions be admission, so that it could not be examined. For hirty hours of his life he passed no urine. A catheter was introduced into the bladder at 9.30 P.M., but the bladder was empty. [At the necropsy the bladder contained only half a drachm of urine.] He was ordered to have warm fomentations to the abdomen, and to have the extremities, which were rather cold and clammy, kept warm by hot-water bottles, and to take brandy and milk. After the application of warmth his pulse improved in volume very slightly, but could not be counted with certainty; heart beats 88 per minute. As I considered the case to be essentially one of muscarin poisoning, I gave him, at 12 noon, atropine (gr. $\frac{1}{75}$) hypodermically. An hour later the pulse was still difficult to count; the heart was beating regularly, 136 to the minute. He was less drowsy. The pupils were unaffected.—3.30 P.M. (three hours and a half after the first dose of atropine): Pulse much better and easily counted; 104 per minute. Pupils slightly dilated, but react to light. Patient has slept for a short time, and says he feels much better. The abdomen is flat and somewhat retracted, and he still complains of pain. He has vomited once, and the bowels have been moved twice since 1 P.M. His face, which in the morning looked pale and pinched, has improved in colour. He was ordered to have a second dose of the atropine (gr. $\frac{1}{75}$) hypodermically, and to take twenty minims each of spirit of ether and aromatic spirit of ammonia every two hours.—8 P.M.: Patient became rather worse at 5 P.M. He was restless and slightly delirious. The diarrhœa and vomiting continued. The pupils were slightly dilated, but reacted to light. He has passed no urine. He vomited each dose of the ether and ammonia medicine, and it was consequently discontinued and an increased dose of brandy substituted. Pulse very small and wiry, 128 per minute.—9.30 P.M.: Catheter passed; no urine in bladder.

Aug. 23rd.—10 A.M.: Patient passed a very restless night; the pupils are not dilated; the face is slightly flushed; temperature subnormal; tongue moist, and coated with a thin yellowish fur. Bowels moved twice during the night. Vomiting has ceased, and he has taken the brandy well. Urine still suppressed. Abdomen retracted, and pain in bowels worse; tenderness on palpation in both lumbar regions. Pulse cannot be counted at the wrist; heart beats 104. He was ordered a hypodermic injection of one-sixth of a grain of morphia. No morphia had been given before because of his drowsiness, but this had now disappeared and the abdominal pain was extreme.—2 P.M.: Patient was not so well. Pulse could not be felt at the wrist at all; heart beats 84 per minute.—2.30: Heart beats 120; respiration sighing.—4 P.M.: Death.

On Aug. 24th, at 2.30 P.M., a necropsy was made, twenty-two hours and a half after death. Rigor mortis well marked. Punctiform ecchymoses on the surface of the left lung, scattered about under the visceral pleura, and grouped together in large numbers where external support was least, especially along the margins of the base. Lung substance congested, but crepitant. Right lung so firmly adherent as only to be removed piecemeal; base and posterior part of upper and middle lobes in a condition of hypostatic pneumonia. Punctiform ecchymoses numerous under the visceral pericardium, especially along the interventricular septum and at the roots of the large vessels. Weight of heart 11¾ oz.; muscular substance pale; left ventricle firmly contracted, empty; the right contained a small quantity of recent black clot; valves healthy; abundant post-mortem staining. The liver weighed 4 lb., and was in an advanced condition of fatty infiltration; weight of right kidney 4 oz.; capsule easily stripped; section pale and *anæmic*. The left kidney weighed 4¼ oz.; capsule easily stripped; pyramids not quite so pale as right; weight of spleen 6 oz. The bladder contained scarcely half a drachm of urine. The stomach contained about three ounces of milk curd and brown-coloured fluid. The mucous membrane was covered with tenacious mucus, and was much congested. There were numerous points of capillary hæmorrhage, and at the cardiac end numerous superficial excoriations about the size of a millet-seed. The whole of the small intestine was slightly congested, and this condition was very marked in the lower two feet of the ileum, where the solitary glands were very conspicuous, and stood out prominently like millet-seeds. The contents of the small intestine were chiefly mucus and intestinal fluid, with a very little curdled milk. The large intestine contained some fluid consisting chiefly of mucus and milk. The brain was not examined.

On the evening of Aug. 20th a little girl, aged three years and a half, the daughter of the above patient, ate part

of one of the "mushrooms." She was a delicate child, suffering from rickets, and had never walked. She was taken ill and vomited at 10 A.M. on the next morning, and complained of thirst. She was purged, but did not suffer from abdominal pain. There was no sweating, no suppression of urine, or drowsiness. She was seen by Mr. T. E. Lovegrove (to whom I am indebted for many of these details) about midnight, and died at 1 A.M. on Aug. 22nd, about twenty-nine hours after eating the "mushroom." The necropsy was made at the General Hospital at 4 P.M. on the 24th, sixty-three hours after death. Decomposition was commencing. The left ventricle of the heart was contracted and empty; the right ventricle and auricle contained recent black blood clot. There was much post-mortem staining, but no punctiform ecchymoses, such as were seen in the previous case. The bladder contained only a few drops of urine. The kidneys were much congested. There were no definite signs of gastro-intestinal irritation. There was abundant evidence of rickets. The brain was not examined.

Remarks.—Though alarming symptoms from "mushroom" poisoning are common, a fatal result is not usual. Agaricus (Amanita) phalloides has previously caused fatal poisoning, notably in some cases at King's Lynn a few years ago. It is most closely allied to Agaricus (Amanita) muscaria, from which the active principle muscarin is obtained. The symptoms, on the whole, so closely resembled those produced by muscarin, that I assume that this was the chief noxious principle. The following points are worthy of attention. Neither salivation nor lacrymation was observed in these cases. Though muscarin, topically applied, at once arrests the frog's heart and slows the heart of mammals, the pulse in this case was not slowed. This corresponds with its action as previously observed in human beings by Morshead and Ringer. Neither was the rapidity of the respiration affected, agreeing again with the experience of Ringer. A more important practical point is the antagonism of atropia. Ringer[1] says, muscarin arrests the heart in diastole, diminishes the blood pressure, depresses the circulation, causes strong contraction of the intestines and bladder, lessens urinary secretion, even to the point of suppression, and contracts the pupil. In all these particulars atropia promptly antagonises muscarin. Schiff believes that poisonous mushrooms produce other symptoms than can be accounted for by the action of muscarin, and he is led to believe that they contain two active ingredients, one having an opposite and the other a simllar action to that of atropia. Lauder Brunton, in his Text-book of Pharmacology, recommends from two to four minims of liq. atropiæ, to be injected hypodermically in cases of mushroom poisoning. In this case one minim was injected twice at short intervals, and after the second dose the physiological effects of atropia were evident. The chief benefit was on the pulse, but the improvement was so slight and transient as to be very disappointing. It is true, the atropia may have been used too late, and that had I had an opportunity of trying it earlier the patient might have had a better chance. The pale, anæmic state of the kidneys shows that the suppression of urine was not due to renal engorgement, notwithstanding the lumbar pain. Whether it was due to contraction of the renal arterioles, to the specific action of muscarin on the renal epithelium, or, as is more probable, to the excessive drain of fluid from the blood by the inordinate watery purgation, I cannot say. I have previously tried atropine injected subcutaneously as an antidote in two cases of opium poisoning, but in each case without success. It is true that both cases were very unfavourable from the length of time that had elapsed before treatment could be commenced. Had they been less serious, probably atropine would not have been used.

[1] Handbook of Therapeutics, Eighth Edition, p. 489.

EDINBURGH MEDICAL MISSIONARY SOCIETY.—The annual meeting of this Society was held on the 18th inst., Mr. William Brown, F.R.C.S., president, in the chair. The accounts submitted showed that the income for the year, including £7024 of a balance from the previous year and legacies amounting to £3472, reached the sum of £15,902. After paying all expenditure, there remained an invested fund of £11,086, which had thus increased by £4012. The secretary, the Rev. John Lowe, afterwards submitted the annual report, which stated that steadily and manifestly the work of the Society continued to prosper.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF TRANSVERSE FRACTURE OF THE SCAPULA BELOW THE SPINE.

BY G. E. DOBSON, M.A., M.B., F.R.S.,
SURGEON-MAJOR, ARMY MEDICAL STAFF.

BOMBARDIER G. J——, Royal Horse Artillery, was admitted to hospital suffering from pain in the right scapular region, increased by motion of any kind, and especially so by motion of the right arm outwards and forwards. While engaged in assisting to move a heavy iron target he slipped and fell, and was immediately conscious of a sharp pain in the back of the right shoulder-blade, so much increased when he attempted to move the right arm that he was unable to continue to perform his duties. He was quite sure that the target had not fallen on him; while helping to carry it he had slipped on some round stones, and he believed that the weight of the target on his arm when he tried to prevent himself from falling had caused something to give way behind his shoulder.

On examination there was not the slightest sign of a contusion, or of any external violence. The form of the right shoulder and scapular region did not differ from that of the corresponding parts on the opposite side. The patient was able to place (though with pain) the fingers of the right hand on the left shoulder. On moving the right arm outwards from the side loud crepitus could be heard in the right scapula, and this with the aid of a stethoscope could be easily localised to the infra-spinous fossa. The case was diagnosed as a transverse fracture of the body of the scapula below the spine.

The right arm was supported in a sling and fixed by a bandage to the side of the body. A piece of gutta-percha, softened in warm water, was closely applied to, and accurately moulded over, the scapula and shoulder, and maintained in position by a bandage. Fourteen days afterwards the bandages and gutta-percha were removed, when some slight crepitus could still be detected with the aid of a stethoscope. The gutta-percha and bandages were replaced and allowed to remain for ten days, at the expiration of which period the crepitus was found to have altogether ceased; the patient had full use of the limb without pain, and he was discharged to duty.

The injury in question was evidently occasioned by muscular force. The patient slipped when engaged in sustaining a heavy weight, and in trying to make good his foothold and also sustain the weight the latissimus dorsi muscle was brought suddenly into violent action, when the inferior angle of the scapula, across which it extends, was also forcibly moved outwards and backwards against the tense body of the muscle, and, the upper part of the bone being fixed, fracture took place at a point between the opposing forces.

Exeter.

PUERPERAL ECLAMPSIA TREATED WITH PILOCARPINE.

BY T. COKE SQUANCE, M.D., F.R.M.S.,
SURGEON TO THE HOSPITAL FOR WOMEN AND CHILDREN, SUNDERLAND.

EARLY on the morning of September 8th I was called to attend Mrs. L——, aged twenty-two, in her first confinement, her ordinary medical attendant being from home. I was informed that the "pains were slow," that she had been very sick, and complained of severe "pain in the head." On examination I found the os well dilated, head presenting, and membranes (which were very tough) unruptured. I ruptured the membranes and applied a binder, but after waiting for some time the pains became very feeble, and the patient showed such signs of exhaustion that I proceeded to deliver her with the forceps, subsequently removing the placenta, which was partially adherent. There was no hæmorrhage worth speaking of, and half an hour after the patient expressed herself as "feeling well." Her pulse when

I left her was 72. Later on I received a message to the effect that she was "going from one fit into another." On my arrival I found her quite unconscious, face flushed, pupils widely dilated, skin harsh and dry, abdomen tympanitic, bladder empty, feet œdematous, pulse 120 and full, and temperature 100°. Her friends informed me that she had had about a dozen exceedingly severe fits, during some of which they thought she was dead. During the "fits" she had passed fæces and urine. As an attack was evidently just commencing, I gave her a hypodermic injection of pilocarpine (¼ grain). The head was then being turned from side to side, the eyelids and eyeballs were moving rapidly, the mouth was drawn up towards the right ear, and the head turned towards the right shoulder, the countenance being of a livid hue. The fingers and thumbs were then flexed on the hands, the latter being strongly flexed on the arms, which were also somewhat flexed, the trunk and legs became rigid. The left leg was raised from the bed, and remained extended for fifteen seconds. There was a peculiar hissing sound on respiration, with convulsive movements of the larynx, the face becoming blue-black in colour, and the patient seemingly on the verge of suffocation. The rigidity, which lasted for fifteen seconds, was followed by clonic convulsions, the face was frightfully distorted, and large quantities of frothy foam slightly tinged with blood came from the mouth. Respiration became restored and the convulsion ceased, with the exception of a little twitching, at the end of three minutes, by which time the patient was in a profuse perspiration. The attendant told me that this attack was barely half the duration of the previous ones. There was no further seizure until shortly before I saw her the next morning, when there was a slight attack. I repeated the pilocarpine then and once subsequently, and no further seizures occurred. She remained unconscious for three days, during which time urine was passed in large quantities. There was an abundant secretion of milk. When I terminated my attendance at the end of a week, her own medical attendant having returned home, she was making most favourable progress. In addition to the pilocarpine, I ordered her a mixture containing chloral hydrate and bromide of potassium, and pessaries of eucalyptus and perchloride of mercury per vaginam.

Sunderland.

REMARKABLE SEQUELA OF MEASLES.

By HARWOOD CASSON, L.R.C.P. LOND.

A BRIEF record of a case personally interesting to myself, as it happened to my own child, may be of sufficient rarity to allow of its insertion in THE LANCET, and prove of interest to others.

L. C——, a tall, well-grown boy of twelve, after a rather severe attack of measles, during which a temperature of from 104° to 105° was maintained for three days, presented symptoms of decided mental aberration, culminating quickly in a condition of dementia. An active, happy, intelligent lad, a companion and comfort to his parents, before this attack, he now wandered about the house in a listless, aimless manner, seizing and consuming anything eatable or drinkable that came within his reach, never speaking unless spoken to, and then in a monosyllabic whisper. His memory was quite gone; and after some absurd reply to a question, when emphatically urged to "think," he would apparently make some weak and transient mental effort, and become exhausted in a moment. His muscular actions were steady and strong, and coördinative power perfect. As a proof of this I may state that he purloined a bicycle (52 in.) which had been left outside, mounted it unaided, and rode it round a stable yard (though in an erratic manner), when a groom ran up and dismounted him. The extraordinary part of this feat is that he had never previously ridden a bicycle of any description (as he now tells us). He slept soundly at night, and had an afternoon *siesta* of two hours daily. On Oct. 5th, twenty-eight days after the appearance of the rash, after remaining in this demented condition for a fortnight, he woke from his afternoon nap, when his voice had become sonorous, his mind clear, and his memory perfect with regard to all the events of the past fortnight, which he imagined himself to have dreamed. At first somewhat frightened to find his late dreams had been actual occurrences, he soon found amusement in recalling all his absurd actions and the equally absurd motives which guided them. He remains well.

The points of interest here seem to be: the abnormally acquired balancing power which enabled him to steer a bicycle without accident; and the sudden and complete recovery of voice, mind, and memory—not least, the recollection of all that had been said to him during his condition of somnambulism (for I scarcely know what else to call it).

ST. THOMAS'S HOSPITAL.

PUNCTURED WOUND OF BRAIN; REMOVAL OF BONE; HERNIA CEREBRI; DEATH FROM DIPHTHERIA SIX WEEKS LATER; NECROPSY.

(Under the care of Mr. MACKELLAR.)

IN small punctured wounds of the skull in children it is not always easy to say at first sight whether the soft bone beneath has been penetrated or not, and the following case shows the importance of careful examination with the view of determining this point, even though the history of the injury may not point to anything so serious. In cases such as this, where the wound is inflicted by a dirty instrument, it is not always possible to clean the damaged part so thoroughly as to prevent suppuration. In the subjoined case the suppuration of the wound was followed by hernia cerebri, and later for a time by the oozing of a thin watery fluid from it. At the time of death, which unfortunately occurred from diphtheria, the child had apparently recovered from the effect of the injury for which she was admitted. For the following notes we are indebted to Mr. Cameron Kidd, late house-surgeon:—

Emily J——, aged two years, was brought to the hospital at 11.45 on the night of July 6th, 1886. The parents stated that at about half-past eight that evening a wooden paling had fallen down on the child, inflicting a wound on the forehead. They consulted a doctor, who put a simple dressing on the wound and sent the child home. On their return, a neighbour, who had been examining the paling, pointed out to them that on a projecting nail in the fence there was sticking a piece of blood-stained bone; being alarmed at this, they applied at the hospital. The piece of bone produced measured three-quarters of an inch long and nearly half an inch wide, and consisted chiefly of the inner table of the skull, with a much smaller area of the outer table.

On examination, the child, who appeared not to be suffering in any way from the effects of the injury, presented on the left frontal eminence a small wound measuring less than half an inch in its longest diameter; the wound had the appearance of having been caused by a pointed instrument. There was a piece of brain substance presenting, and from its centre a small spicule of bone protruded. This being extracted with forceps was found to be a small plate of bone, apparently the inner table, measuring a quarter of an inch by one-third of an inch. A second fragment, a little smaller than this, was then seen and removed. When this had been done, lacerated brain substance was distinctly seen at the bottom of the wound. Two hours after admission, with a view to removing all fragments, Mr. Mackellar enlarged the wound in two directions under chloroform, and removed several small splinters of bone, at the same time chipping off the roughened edges of the fracture. The wound was well washed with carbolic solution (1 in 40), closed with catgut sutures, and dressed with iodoform gauze and salicylic wool. During the operation the dura mater was seen to be punctured, and brain substance was protruding through it.

July 7th.—Slight sickness after the chloroform. Child quite quiet all day. Passed urine and motions in the bed.

The temperature rose steadily all day—was 102° at noon, and 105° at 8 P.M. In the evening the pulse was 200, and the respiration 60. Taking three grains of grey powder three times a day.

8th.—Slept well; sat up this morning and took some milk voluntarily. Temperature in the evening 102°; pulse 150. Wound dressed; quite healthy.

9th.—Slept well. Temperature normal in the morning; 103° at 8 P.M. Child seems wonderfully well, sitting up in bed and asking for milk. Pulse 116, good, regular; respiration 20. Urine and motions still passed in bed.

11th.—Child keeps well. Temperature 100° in the evening. Stitches have given way and the wound is suppurating. There is slight hernia cerebri.

15th.—Child is looking pale and is fretful at times, but sleeps well after being given five grains of bromide of potassium occasionally. Takes about a pint of milk and some infants' food.

19th.—The temperature has kept normal since the 11th. Wound suppurating freely and gaping more, but hernia not more prominent.

23rd.—Wound still suppurating freely; hernia cerebri no longer protrudes; wound smaller. To-day the temperature rose to 102·8°. Bowels not open for two days. Three grains of grey powder ordered. Takes bread-and-butter, custard pudding, and beef-tea; appetite good. Has not needed bromide for some days.

25th.—Temperature normal again. Hernia almost disappeared.

28th.—Wound dressed daily; healing slowly; granulations just level with the surface; it pulsates freely.

Aug. 3rd.—Wound dressed with sulphate of zinc lotion; granulations healthy.

11th.—Wound healing well; no pulsation.

12th.—Temperature went up to 102·6° at midday. Child seemed ill, not taking food so well as usual. Wound looks glazed, and pulsates again slightly.

13th.—Morning temperature 102·8°. Child restless; wound looks more glazed, with a slight discharge of thin watery fluid. Pulsating distinctly. Temperature in the evening 105·2°. No rash. Three grains of grey powder given at night. Ice-bag to head.

14th.—Morning temperature 104·2°. Breathing rapid and shallow. Some enlarged and tender glands in the neck. Tonsils found to be covered with yellowish sloughs. Wound discharging watery fluid more freely. Temperature in the evening normal. During the day the hands were noticed to close spasmodically without cause.

17th.—Extremely restless all day, screaming, picking the bedclothes, and tossing about. Wound still discharging watery fluid, and pulsating. Right eyelid distinctly drooping, but she can fully open the eye with an effort. Temperature normal.

19th.—A good night after ten grains of bromide of potassium. Throat much better. Temperature normal.

21st.—Better in every way. Temperature normal. Not restless. Wound still pulsates.

23rd.—The temperature yesterday rose to 100·4°, and again to-day. Wound pulsating freely. Some watery discharge this morning.

26th.—Temperature 101·4°. Breathing embarrassed; whitish membrane seen on the tonsils. Transferred to diphtheria ward in the evening.

27th.—Breathing still embarrassed. Temperature 100° to 101·6°. Wound in much the same condition.

28th.—Worse. Considerable retraction of ribs this morning, with lividity of face. The child was placed under the influence of chloroform and tracheotomy performed. Her urgent symptoms were at once relieved. Next day the temperature was 101·8°, but the respirations were again embarrassed, and there was evident obstruction below the wound. She lived until the afternoon of the 30th, and then died from extension of the mischief, the temperature being 102°.

Necropsy.—At the post-mortem examination, the larynx, trachea, and larger bronchi were found completely blocked by a uniform lining of diphtheritic membrane. The wound in the forehead was found almost healed under a scab, the hole in the skull being about the size of a shilling, with irregular outline. The dura mater was generally attached to the interior of the skull. The tip of the left frontal lobe was adherent to the dura mater at the site of the wound, but it was perfectly healthy, though a little pigmented. The rest of the brain was free from disease.

GUY'S HOSPITAL.

CASES OF RENAL SURGERY.

(Under the care of Mr. CLEMENT LUCAS.)

THE following short account of two cases, which have been recently operated on, will prove of interest to our readers. They are illustrative of the renal surgery of the present day, and the fact that they are reported so briefly proves that these operations are becoming more frequently performed.

On Sept. 29th Mr. Clement Lucas operated in this hospital upon a married woman, aged thirty-seven, who had been suffering for some years from a painful movable right kidney, which of late had incapacitated her for household duties. She was sent to London by Mr. Cockell of West Hartlepool. The kidney was exposed through the loin, and stitched to the lumbar aponeurosis. The immediate effect of the operation was to completely remove the pain. The wound healed primarily, except at one spot (where a stitch afterwards escaped), and she remained free from pain up to the time she left the hospital.

On Oct. 29th Mr. Lucas performed nephro-lithotomy upon a patient sent by Mr. Waller from Sydenham. She was an unmarried woman, aged thirty-nine, who had suffered from symptoms of renal calculus for six or seven years. A conical stone, seven-eighths of an inch in its two longest diameters, was extracted from the pelvis of the right kidney. The wound is now healed, and the patient convalescent. Since the operation the amount of urine has doubled, indicating that previously the conical stone was acting as a stopcock to the top of the ureter.

CHICHESTER INFIRMARY.

COMPOUND COMMINUTED AND DEPRESSED FRACTURE OF THE FRONTAL AND PARIETAL BONES; TREPHINING AND RECOVERY.

(Under the care of Mr. SKAIFE.)

IN THE LANCET of October 16th, page 723, we published a case somewhat similar to the following, in which the patient recovered, and with which it may be compared. The cause was alike in each, and also the extent of damage produced by the injury, the chief difference being in the position of the fracture which in the former was situated over the occipital bone. For the notes of this case we are indebted to Mr. J. Rushworth Kull, house-surgeon.

F. L——, a sharp, intelligent boy, about eight years of age, was admitted into the infirmary on June 14th, 1886. It was stated that whilst running after a ball he was struck by a large swing boat. When first seen, the boy was quite conscious and able to give his name. His extremities were cold; pupils equal and acting to light. He had not vomited.

On examination two punctured wounds were found over the lower and left portion of the frontal bone, close to the anterior inferior angle of the left parietal bone, but rather above. A distinct rounded depression could be felt about an inch and a half in diameter. There was a fair amount of hæmorrhage.

The patient being put under chloroform, an incision was made down to the bone connecting the two punctures. The bone was then found to be split into three triangular portions, the pointed ends projecting into the brain. Though there were no direct symptoms of compression, it was thought absolutely necessary to elevate the depressed portions. Accordingly a semilunar piece of bone was removed by the trephine, and a triangular loose piece with an elevator. A small piece of brain matter half the size of a pea came away; otherwise the dura mater was intact. The wound was now thoroughly washed out with a solution of carbolic (1 in 40), the edges drawn together, four wire sutures introduced, and dressed with green protective, salicylic wool, and gauze (carbolised). The edges were powdered with iodoform. The patient was sick twice during the operation. On being put to bed, milk and ice in minute quantities were ordered, but the former making him sick it was discontinued. He was ordered a powder consisting of three grains of calomel one hour after operation. Pulse 68. Looks comfortable. Temperature 99·4° at 11.45 P.M.

June 15th.—Passed a fair night. Wound dressed under spray; looking healthy. No action of bowels. Ordered

three grains of calomel and ten grains of compound jalap powder. An ice-bag was kept applied to the back of the head for the first three days. Takes a teaspoonful of Brand's essence every two hours, with ice at intervals. Morning temperature 98·4°; evening, 100·4°.

16th.—Had again a good night, with a fair amount of sleep. Wound dressed. Patient says he suffers no pain whatever. Bowels acted twice after the powder. Evening temperature 98·4°.

17th.—Wound dressed. Slept well. Takes milk in small quantities. No headache or sickness. Evening temperature 100·4°.

18th.—Wound dressed. Bowels acted freely after simple enema. Evening temperature 99·2°.

21st.—Wound dressed; a little more discharge, otherwise healthy. Had some minced chicken for dinner.

23rd.—Continues to make an uninterrupted recovery.

29th.—Temperature rose to-day to 102·2°; no ascertainable cause. Says he feels quite well.

30th.—Temperature normal.

July 30th.—The wound is now almost healed. A small piece of exfoliated bone was removed.

Aug. 10th.—Wound quite healed. A cast of the head in plaster was now taken for the purpose of providing the patient with a celluloid plate (over the unprotected portion of the brain), which he now wears.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Ricinus Communis.—Embolic Aneurysms.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

MR. THOMAS DIXSON contributed a paper on Ricinus Communis (communicated by Dr. Lauder Brunton, F.R.S.) The object of the present paper was to throw light on the connexion between the activity of the seeds and that of the oil. The published accounts of poisonings and of investigations into the nature of the seeds were recorded. The author gave the results of experiments on rabbits made with the seeds in their natural state, and with an extract prepared after Bübnow's method. It was pointed out that post-mortem examination showed that when the rabbit was poisoned by castor-oil diarrhœa invariably occurred, death never took place before the second day, and the intestine did not show any trace of congestion or inflammation; but after poisoning by the seeds death might occur in twelve hours without positive diarrhœa, and the intestine always showed excessive vascular engorgement. A description of the castor-oil cake as prepared by the author was given, and it was suggested that as this is highly albuminous, and by cooking becomes harmless, it might be useful as an article of food in India in time of famine.

Messrs. JOHN LANGTON and ANTHONY A. BOWLBY contributed a case of Multiple Embolism of the Arteries of the Extremities followed by the Formation of Aneurysms, with remarks on the relations of Embolism to Aneurysm. The authors described the case of a girl, aged twenty, who was admitted into St. Bartholomew's Hospital, suffering from aneurysmal swellings at the bend of the right elbow and in the right popliteal space, respectively of three and four weeks' duration. The heart was diseased, and the aneurysms were considered to be of embolic origin. After a trial of treatment by rest and pressure, which at first appeared to be beneficial, the swelling in the arm rapidly increased in such a manner as to render it probable that the aneurysm was becoming diffused. On this account the brachial artery was tied above the bend of the elbow, the vessel being secured by two ligatures and divided between them. The operation was followed by cessation of pulsation and slight diminution in the size of the aneurysm. Within a few days the popliteal swelling also began to extend; the superficial femoral artery was therefore tied in Scarpa's triangle, in the same way as the brachial, and with similar good results. Six weeks after admission, the patient had a sudden attack of left hemiplegia, with pain in the right thigh and leg, followed by complete cessation of pulsation in all the arteries of the right lower extremity. The aneurysmal swellings gave no further trouble and slowly decreased in size. The patient became weaker and died eight weeks after admission. A post-mortem examination showed that the heart was the seat of ulcerative endocarditis, and that it had been diseased for a considerable time before death. The aortic valves were covered with vegetations and calcareous matter. The sinuses of Valsalva were dilated so as to form aneurysmal pouches. The aorta at one spot was almost completely ulcerated through. The spleen and kidneys were scarred from the lodgment of emboli. Several of the cerebral vessels were plugged by recent emboli. The swelling at the right elbow was found to be an aneurysmal sac formed by condensation of the soft tissues and by blood-clot. It communicated with the brachial artery by an ulcerated aperture, plugged with clot, situated just above the bifurcation of the vessel. The radial and ulnar arteries immediately below the opening contained calcareous emboli. The right common iliac artery contained a calcareous embolus. At the seat of the embolism the arterial wall was ulcerated, thinned, and expanded. The posterior tibial artery of the right leg opened by a small ulcerated aperture, filled by recent clot, into the sac of a large false aneurysm in the calf, formed by condensation of the soft tissues and by blood-clot. The left external iliac artery presented an aneurysmal dilatation, apparently of recent date. Lower down, both this vessel and the common femoral were entirely occluded by calcareous matter and old decolourised clot. The authors consider that the specimens clearly show that the lodgment of emboli has been followed by the development of aneurysms. They point out that the aneurysms are not formed by dilatation of the artery walls above the embolus, but by inflammation of the coats at the place where they are in contact with the embolus. This inflammation has in some vessels resulted in ulceration, in others in softening and dilatation. After alluding to the published cases in which aneurysms have been attributed to embolism, the authors show that in almost all of them there has been present that form of heart disease which is associated with development of large fungating granulations, and frequently with ulceration of the valves; and they argue that the aneurysms in question only occur in connexion with this special form of heart disease, and are dependent upon the specific characters of the emboli. They give their reasons for believing that vessels never become dilated as a result of their mere mechanical obstruction by an embolus or a ligature, and in conclusion submit the following propositions:—1. Embolism may undoubtedly cause the formation of an aneurysm. 2. The aneurysm is developed at the seat of obstruction, and not above it. 3. The aneurysm may be due to an inflammatory softening and consequent dilatation of the artery, or to its ulceration and the subsequent formation of a sac by the surrounding soft tissues. 4. Aneurysms only occur when the emboli are derived from a heart the valves of which are affected by a special form of disease, resulting in the production of fungous growths, and often of ulceration and destruction of the valves themselves.—Mr. G. D. POLLOCK related the particulars of a somewhat similar case. The patient was a boy aged fourteen. There was heart disease. An aneurysm developed at the bend of the right elbow; it became diffuse, and pressure was employed. The necropsy showed a heart in an entirely similar condition to that shown by the authors. He asked whether these aneurysms were not more frequently seated at the division of arteries.—Dr. PERCY KIDD thought that the most sceptical would now be convinced of the connexion between aneurysm and embolism. He referred to two cases of aneurysm of the cerebral arteries in which there was "warty" or ulcerative endocarditis. The chordæ tendineæ were ruptured in the first case. The orifice of the middle cerebral artery in the aneurysm was distinctly narrowed, and pointed to cicatricial contraction at that seat. There was another embolus in the carotid artery of the cavernous sinus. In the second case, in the right frontal lobe there was a large spherical clot; but no aneurysm could be found of any kind there. A small aneurysm the size of a pea was found in the parietal lobule; the arterial tunics were replaced by inflammatory growths. He considered that there could be no doubt at all that the aneurysms were due to emboli derived from the diseased valves. A calcareous embolus was not a *sine qua non*. But Ponfick's third point, that the artery blocked must be situated in soft tissues, was important. The first case of embolic aneurysm is usually attributed to Tuckwell, but perhaps Kirkes had anticipated him. The

position of arrest of the embolus was laid stress on by Ponfick as being at the distal end of the bifurcation of an artery. But cases of embolic aneurysm were to be found on the proximal side of bifurcation.—Dr. GILBART SMITH said that the embolic theory of aneurysm did not commend itself to him. He thought that there was something beyond the septic condition necessary to the causation of these aneurysms. He had seen blockage of arteries and gangrene in chronic cases of valvular disease. He suggested that the size of an embolus might have something to say in the matter.—Mr. R. BARWELL still held the view that mere mechanical obstruction of a healthy artery could not cause aneurysm. He found himself in almost complete accord with the views of the author. He inquired for the presence of micro-organisms in the coats of the diseased vessels.—Dr. GOODHART said that the septic endocarditis was of the most variable intensity, and could not be judged of solely from a clinical point of view. An aneurysm would require some time to form. Death might occur before they could develop. He had never yet found a case of calcareous embolus, so the condition found in the case narrated by the authors was rare. Ponfick's views on this point he did not accept. The proof in favour of aneurysm from embolism was complete.—Mr. R. W. PARKER thought that the paper did not add much to Dr. Goodhart's theory that the emboli were septic. A proof was still wanted of some septic agency being at work in the formation of the aneurysm. He could not believe that calcareous formations were either septic or of acute character. Was it possible to suppose the presence of an arteritis of primary origin and co-ordinate with valvular cardiac changes? Might not some local condition be present and active in many arteries in the case of the boy related, and neither embolism nor septicity be the cause of the aneurysms?—Mr. LANGTON said that the aneurysms were mostly situate above the division of the main vessel. That a sharp point in the calcareous embolus was not necessary to the formation of aneurysm was evident from the specimens shown. He did not maintain that all such emboli resulted in aneurysm. The case read demonstrated the action of the embolus itself in the formation of the aneurysm, and thus supplied a missing link in the chain of evidence.—Mr. A. A. BOWLBY thought that septic infection of the aortic valves might be in progress without any clinical signs. He did not agree with any of Mr. Parker's observations. He claimed that the calcareous formation was old and the ulceration and granulations new. Except in immediate connexion with the emboli, the vessels were free from disease. Micrococci had been found in the diseased arterial areas, but he did not attach much importance to their presence.—Dr. GILBART SMITH explained that he did not question the embolic origin of the aneurysms in the particular case narrated.

MEDICAL SOCIETY OF LONDON.

Sarcoma of Stomach and Pancreas.—Cancer of Pylorus.—Subacute Atrophy of Liver.—Villous Tumour of Rectum.

AN ordinary meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, President, in the chair.

Dr. LOWE read a paper on Sarcoma of Stomach and Pancreas, in which the right kidney had become obliterated as the result of an accident eleven years before the last illness began. The patient, a gentleman aged sixty-two, of temperate habits, consulted Dr. Lowe for symptoms of indigestion in July, 1882. During the eleven years since the accident the patient had complained of aching and shooting pains in the right loin, but only at times. At first no physical signs were detected, but later a firm round tumour was felt in the left hypochondrium, and a loud bruit could be heard over it. At first aneurysm was thought of, but it was clear that the pulsation was due to transmission of impulse from an artery to the tumour, which was apparently connected with the stomach. Later still, the tumour became softer and an abscess was suggested. But Dr. Lowe, taking into consideration the great wasting and debility without rigors or sweating, diagnosed sarcoma. The patient suffered much pain, the tumour grew in extent, and death followed. The necroscopy was made by Mr. Lindeman, of the West Norfolk and Lynn Hospital. A large solid nodular tumour was found, involving the stomach and omentum; many glands were also enlarged. The pancreas was indistinguishable from the rest of the new growth. The growth was composed of dense fibrous nodules and large cribriform masses. Much lymph was thrown out in the peritoneum, which also contained a purulent fluid. It was believed that the sarcoma originated in the injured kidney and spread to the stomach and pancreas. Dr. Lowe considered that the kidney must have been extensively damaged and its ureter blocked in order to explain the appearances found at the necropsy, for this structure had become converted into a soft pultaceous mass of small size. The left kidney was enlarged, but not diseased. Microscopical examination showed that the growth was a round-celled sarcoma.

Dr. PURCELL read notes of a case of Cancer of the Pylorus with Adhesions to the Abdominal Wall, in a woman aged sixty-two. Another case of Stenosis of the Pylorus by a cauliflower cancer was read.—The PRESIDENT narrated the case of a girl aged ten, from whose orbit he removed an indurated lacrymal gland. The new growth recurred in five years, and was then found to be colloid in character. In two years more there was further recurrence, and then the tumour was discovered to be a spindle-celled sarcoma; the whole orbit was cleared out, including the eyeball. Further recurrence took place, and the patient died ten years after the first appearance of the tumour.—Mr. F. B. JESSETT suggested that the growth began in the stomach, and spread across towards the right kidney.—Dr. SAMUEL WEST supported Dr. Lowe's view of the case by the narration of a case of cancer, which began in the gall-bladder and yet was most abundant and extensive at a distance from its site of origin.

Dr. SAMUEL WEST read a case of Subacute Atrophy of the Liver. The case might clinically be called one of malignant jaundice. It was that of a woman, aged twenty-eight, whose illness began with matutinal vomiting five months before admission. Jaundice had lasted one month, and delirium had been present two weeks. She had been married seven years, and five times pregnant; was a barmaid, but not addicted to habits of drinking. Profound prostration was a marked feature. The urine was albuminous and scanty; it contained much bile pigment, but no tyrosin or leucin, and no bile acids. There was some fever, but the temperature was not above 101°. Delirium was more and more continuous, and finally the patient became almost unconscious. At first there was enlargement of the liver, wtih some tenderness. The blood was found to be normal. A typhoid state ushered in the fatal termination, which occurred nineteen days after admission. The liver weighed fifty-three ounces, and appeared smaller than natural. Microscopic sections showed stained and unstained areas in hæmatoxylon preparations. The unstained areas were composed of a kind of connective tissue. A small-celled interstitial growth appeared to have been the essential hepatic process, and its tendency to degeneration was suggestive of gummata. Many of its cells had undergone granular atrophy; others a cystic change.

Mr. ALLINGHAM, jun., read a case of Polypoid Growth of the Rectum in a man aged seventy-three. Frequent defecation and passage of slime, with great debility and sensations of numbness down the legs, were the chief symptoms. The tumour was sessile, and had the dimensions of a fœtal head. It was removed by Mr. Allingham on Nov. 17th by means of ligatures. The growth was not malignant; microscopically it consisted of hyperplasia of the rectal crypts.—Mr. JAMES BLACK had seen a similar specimen, but there was considerable hæmorrhage.—Mr. WALTER PYE asked how the ligatures were inserted.—Mr. BENTON had assisted at an operation for a similar large-sized growth in a woman.—Mr. J. H. MORGAN remarked that the shrinking of the tumour was to be explained by the escape of mucus from its follicles.—Dr. C. H. F. ROUTH mentioned a case of a small hard polypus.—In reply, Mr. ALLINGHAM said that the whole tumour was drawn outside before the base of the tumour was ligatured.

OPHTHALMOLOGICAL SOCIETY.

President's Address.—Tumour of Optic Nerve-sheath.—Proptosis with Pulsation.—Acute Glaucoma.

AN ordinary meeting of this Society was held on the 11th inst., Mr. J. Whitaker Hulke, F.R.S., President, in the chair.

Mr. HULKE, on taking the presidential chair for the first time, expressed regret at not having been able to be present at the first meeting of the Society. He hoped that [illegible] which had occurred in

ophthalmic practice within his own recollection would be of interest. In the days of his pupilage, the opportunities of studying eye diseases were but few; of the general hospitals, Guy's alone had a special department. The Royal London, the Westminster, and the recently instituted Central London were the special hospitals. The ophthalmoscope was then unknown, and its discovery a little later caused a revolution in the treatment of diseases of the eye; and he well remembered the pleasure with which he first saw the fundus through Helmholtz's original ophthalmoscope. Later on, there appeared the instrument of Anagnostakis, and subsequently Zehender's combination of a convex mirror and collecting lenses. Guthrie was the leading surgeon at the Westminster Ophthalmic Hospital when he began his studies in 1848; he was a strict disciplinarian, a clear-headed man, and an energetic, prompt, and dexterous operator. His method of treating severe trachoma by nitrate of silver and lard was widely known, the preparation being called Guthrie's black ointment. For entropion he used to make a scar parallel to the diseased lid with fuming nitric or sulphuric acid. In those days, amaurosis, or one form of it, was supposed to be due to constriction of the optic nerve by the muscle at the apex of the orbit, and accordingly tenotomy of all the recti was performed for its relief. The old operation for squint was very different from the subcutaneous method of modern days. Cataracts were then always treated by discission—an operation that was modified by Dr. Jacob of Dublin. Keratonysis had from very early days been the recognised operation for the soft cataract of early life, and still held its ground. He inclined to the belief that these cataracts were congenital rather than infantile. Extraction was regarded as the test of dexterity in an operator; and, as then performed, required far more dexterity than in the operation of their own days, the linear extraction of von Graefe. Amongst other operations, he mentioned iridesis and iridodesis, which, as performed by its inventor, the late Mr. Critchett, was a beautiful operation, but in other hands had not proved a great success, and had fallen into disrepute on account of the danger of iridocyclitis. A. von Graefe's great discovery of iridectomy as a means of permanently reducing the tension in glaucoma was referred to as the greatest advance of modern times, which would make Graefe's name famous for ages to come. A brief account of the old method of excising the eyeball, and of the changes which have followed the introduction of anæsthetics, brought this interesting address to a close.

Dr. BRAILEY showed a microscopical preparation and drawing of Sarcoma growing from the Dural Sheath of the Optic Nerve. The patient was a woman aged forty-two, whose left eye protruded for three-quarters of an inch directly forwards. Both lids were large, flaccid, and doughy, apparently from enlargement of the subcutaneous veins. The conjunctival vessels on the outer side were also enlarged. The eye-movements were much limited to the inner side, and still more so in other directions. The pupil was without direct reflex or associated action, but the indirect reflex action was present. Perception of light was wanting. The optic disc was rather raised, slightly ill-defined, and whitish; its vessels were enormously tortuous, lying in loops on its upper portion. Some small white striated inflammatory patches were found just beneath the disc margin. The other eye and the rest of the body showed no evidence of any morbid condition. The mass was excised together with the eyeball. It was found to surround the optic nerve, and to be much thicker on its outer side. Posteriorly the nerve tapered off to a fibrous tract in the substance of the tumour. The growth measured about an inch and a quarter in each diameter, and occupied the space within the recti muscles, from the apex of the orbit close up to the eyeball. It was firm and pretty smooth, and but scantily provided with blood-vessels. Microscopically, it was connected in its origin with the extreme peripheral part of the dural sheath. Fibrous trabeculæ started from the latter, and formed by their anastomosis loculi, in each of which was embedded a rounded abundantly nucleated mass. The nuclei were large and oval, and were embedded in a scanty finely fibrillated basis substance. They had a whorled arrangement, as if they had been originally deposited round the sheath, or in the place of a bloodvessel. Two similar rounded, nucleated, whorled masses had extended into the optic nerve in the place of the central artery and vein respectively. Passing further from the dural sheath, the trabeculæ generally became slighter, and the nucleated masses smaller and more rounded. The author thought that [illegible] nerve-sheath was a rarity, and he never remembered to have seen one presenting this character. It must be described as a fibro-sarcoma. Its history, commencing eight years previously, with very gradual proptosis and early loss of sight, and afterwards marked by gradual painless increase, appeared to him remarkable in connexion with the abundantly nucleated character of the mass, and the absence of deposits in other parts.—Mr. HULKE gave an outline of a similar case that occurred in a young woman aged twenty-two. There was marked proptosis. The tumour grew from the dural sheath of the nerve within the orbit. It was of sarcomatous structure, with the fibrous tissue element rather predominant. The tumour had grown very slowly (fourteen years).—Dr. SEYMOUR SHARKEY had seen one case in which the tumour grew into the frontal lobe of the brain. Billroth had also pictured this variety of tumour in his "Surgical Pathology."

Mr. G. E. WALKER (Liverpool) showed some patients illustrative of the Treatment of Glaucoma. The first was a man, aged forty-three, who was seized with acute glaucoma in August, 1885. His illness commenced with chill, pain in the left side of the head, and in the left eye. He was treated for two months with drops, during which time his sight deteriorated, but pain became less. A second attack was also similarly treated for other two months, after which sight was completely lost. In April he came under Mr. Walker's care, when his sight had been extinct for a fortnight, and the eye stony hard; eserine was dropped into the eye, and cyclotomy done with the narrowest possible knife; the pain was stopped at once, and finally. On the third day after the operation, and subsequently, eserine drops were used. There had been no pain since, and the tension of the eye was almost normal. Mr. Walker then proceeded to refer to two cases of glaucoma treated by convex lenses that he had brought under the notice of the Society in April, 1886. One of them was seen in Dublin on the 30th of August, and was found to be quite well then, and is so still. The other who was shown was the same patient who had been brought to London at the time of the former meeting, but who had an attack of glaucoma on the evening of the meeting, and could not be shown. His symptoms had been relieved by his wearing a convex glass of 2 D.—Dr. BRAILEY admitted that the man had improved, but it was not an original treatment. Convex glasses doubtless prevent glaucoma up to a certain point, but it would not always be effective. He mentioned the case of a lady who was greatly benefited by convex glasses, which did not, however, entirely prevent attacks of glaucoma.—Mr. NETTLESHIP had examined the right eye of the case shown. The disc was cupped and the retinal veins engorged. He could not consider that the man was altogether free from increased tension.—Mr. MCHARDY considered that the man still presented all the ordinary symptoms of chronic glaucoma in the right eye. Charts of the field of vision ought to be given. The left eye may have reached a very bad state before iridectomy was performed; so that bad result need not be attributed to the operation. The further history of the case would doubtless prove most instructive.—Mr. JONATHAN HUTCHINSON could not agree that convex glasses were sufficient to cure all cases of glaucoma; for it was the custom to give glasses to correct hypermetropia in cases of threatened glaucoma.—Mr. WALKER, in reply, said he should be happy to give the sequel of the case in due course. The cases showed the correctness of his view that excessive action of the ciliary muscle was the cause of glaucoma. It was not the iridectomy that did good, but the sub-conjunctival fistula which frequently resulted from the incision in the sclerotic. He advocated extraction of cataract without iridectomy by an incision across the upper part of the cornea. As to the question of originality raised by Dr. Brailey, he had conceived the idea more than ten years ago, and had spoken of it at Moorfields again and again, and it was in print eight years ago. If anyone could show a claim prior to this, he would abandon his.

Mr. G. E. WALKER also showed a boy, aged sixteen, with a certain degree of Unilateral Proptosis of the right eye. His history was that he had slipped down some stairs, and had struck his head so as to render himself unconscious for three days. There had been no bleeding from the ears or nose, or other proof of fracture. On recovering consciousness he noticed a swishing noise in his head, and five months later his right eye had become engorged and protruded, the left also was for a little while unduly engorged. The disease had been slowly progressing since it was first noticed.

The diagnosis lay between a communication between the artery and the cavernous sinus and a true aneurysm. He had been in favour of tying the common carotid artery, but Mr. Hutchinson and Mr. Holmes had advised delay, and he was anxious to hear the opinion of the members of the Society.

Mr. JONATHAN HUTCHINSON thought the probable nature of the case was one of communication between the carotid artery and the cavernous sinus. The degree of turgescence in the conjunctiva and in the central vein of the optic disc was noteworthy.—Dr. BRAILEY referred to a case in Guy's Hospital of a boy aged sixteen in whom the pulsation and proptosis developed after an injury to the head.—Mr. EALES related a case of head injury in a coal-miner, which was followed by the development of an orbital aneurysm. Both pulsation and thrill existed. Ligature of the carotid artery was being considered when the humming in the head suddenly ceased. This was a case, therefore, of spontaneous cure. In some cases digital pressure might be followed by relief. Mr. ADAMS FROST mentioned the case of a man aged forty-three who had fractured base at the age of ten. The signs of pulsating tumour still continued, but without increasing.—Mr. HULKE spoke of a case of the kind in which the left common carotid artery was ligatured with a good result at first, but the signs reappeared. It was not certain, therefore, that ligature would lead to a permanent cure. Nélaton had shown that a continuous hum was a feature of the arterio-venous aneurysm, and this was the probable nature of Mr. Walker's case. Such cases often made very slow progress. Thrombosis of the cavernous sinus may cause all the signs of aneurysm. The case of a woman who sustained a blow in the face and in whom proptosis and pulsation followed was related. The common carotid artery was tied, but secondary hæmorrhage and pyæmia resulted in death. There was no communication between any artery or vein, and the only lesion that would explain the clinical phenomena was thrombosis of the cavernous sinus.—Mr. WALKER has since made a prolonged and careful examination, and finds that the sounds under all conditions of the heart's action are divided by a distinct pause, so that the aneurysmal view seemed to be favoured.

Mr. W. LANG showed the following living specimens:—Rodent Ulcer, in a man aged sixty, on the upper eyelid at the inner canthus; Lupus of Conjunctiva in a girl aged sixteen; Recurrent Sarcoma of Orbit in a girl aged ten.

Reviews and Notices of Books.

Lays of the Colleges: being a collection of Songs and Verses by Members of the Æsculapian, Medico-Chirurgical, and other Professional Clubs in Edinburgh. Edinburgh: Maclachlan and Stewart. 1886.

MEDICINE and literature are old allies. The most human of all vocations has ever taken kindly to the "humanities." So it was in ancient and mediæval times; so it was at the Renaissance; so it is in the nineteenth century. An instructive essay might be written on Carlyle's thesis, that the physician, even more than the jurist or the theologian, can develop into the man of letters—ay, even "into the singer." From Goldsmith in the last century to Oliver Wendell Holmes in this, how many figures in literature and poetry recur to the memory as having risen out of the healer's training and career! Scotland alone could furnish examples enough to prove the twinship of the two callings, medical and literary. At the Renaissance and for a century after, when Latin was the favoured medium of prose and verse, she could point to Arthur Johnston and Archibald Pitcairne as at once physicians and poets of European renown. In Smollett as a master of prose fiction, in Mackintosh as a pioneer in historical and political philosophy, she has produced "instantiæ prærogativæ," in Baconian phrase, of the close relation as to culture and authorship between medicine and literature. In all her seats of learning she has maintained the healthy tradition; and even throughout the post-Reform Bill or Mechanics' Institute period, when a *bourgeois* utilitarianism tried hard to expel the graces from school and college, she outrode the materialising storm, and kept faithful to the precept of the brothers Humboldt—"Cherish the beautiful; the useful will take care of itself."

These "College Lays" are yet another proof of this kindly fusion of science and poetry—of culture's "two-celled heart, beating with one full stroke." The volume, as the preface to it reminds us, perpetuates the pleasant custom of more than a hundred years of professional, particularly medical, life in Edinburgh—the custom, to wit, of relieving by literary symposia the strain and stress of work in class-room, in hospital, or by bedside. At least four clubs of this kind are represented by these Edinburgh "deipnolyriats," and, significantly enough, the best songs and verses come from the medical. The editor, however, should have remembered the counsel of the prince of the lyric craft—Pindar's counsel—and put at the head of his choral procession the most worthy of the band, instead of reversing this order, and leading off with Dr. Andrew Wood, mounted on a pony Pegasus that sorely wants clipping. As THE LANCET has shown ere this, the worthy Doctor had no ear for rhythm, and not much for rhyme, while his humour seldom rose above the nadir of the humblest verbal antitheses. It is but fair, however, to admit that in his serious vein Dr. Andrew Wood could reach something like the solemn impressiveness of a hymn—witness the touching quatrains on the death of his son (p. 22), and those entitled, "The Time is drawing near." Very different as to his "mount" and its management is the next performer, Sir Douglas Maclagan, a born troubadour, equally at home in Latin, English, or Scotch, in academic chaunt, or gay sporting song, or stirring war stave, or pensive threnody. For genuine "lilt" and "go," few poems of their kind can be classed with his "Saumon," or his "Heather," which, sung to the appropriate airs of "Cauld Kail in Aberdeen," or "Roy's Wife," will long be favourites at winding-up banquets on the eve of exchanging infirmary ward or sick room for rippled stream or empurpled moor. As a translator, too—particularly from the German—Sir Douglas is not a whit inferior to the great master in that *métier*, Sir Theodore Martin, his renderings of Freiligrath, Hauff, and Vogt (pp. 43–7), being quite models of fidelity, felicity, and force. We need not dwell, however, on merits which have long been recognised, and for the same reason we may pass over Professor Blackie's characteristic "Song on Geology," or his still better, "Capped, an' Doctored, an' a'."

Equal in humour, if inferior in finish, to Sir Douglas are the next two contributors, Drs. J. G. Gillespie and John Smith, whose prolific vein suffices between them to fill two-thirds of the volume. "Et cantare pares, et respondere parati," these rival minstrels leave us pretty much in the dilemma of Palæmon between Menalcas and Damœtas in the eclogue, unable to award the palm of superiority. "The Sulphur Cure" of Dr. Gillespie, remarkable for spirit and sly allusion, and winding up with a highly felicitous pun, may be taken as a specimen of his most effective manner; and yet we are not sure that the majority of readers might not prefer to it Dr. John Smith's "Medical Maid"—surely the happiest of all satires on the curious zeal, or rather zealous curiosity, of many an aspiring "Minerva Medica." Occasionally, however, these phenomenally fluent lyrists touch the lower levels of the music-hall, and no justification drawn from the fact that their effusions were meant to be sung, not read, can make admissible such rhymes as "Nisbet" and "kismet" (p. 92), or as "integrity" and "intrepidity" (p. 161). On such easy terms as they often allow themselves a child might versify! At p. 199, moreover, there is an attempt to render "Comin' through the Rye" into rhyming Latin, which reminds us of Father Prout's caustic saying: "The Scotch are more given to boast of Buchanan than to read his writings." Certainly it is not from compatriots of the "Poetarum Scoti" as "facile Princeps," as Henry Stephens [illegible] lator of the Psalms, that we

should expect anything so unutterably faulty in concord, syntax, and prosody.

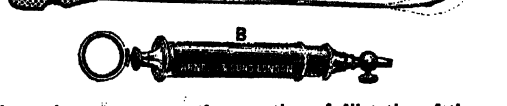
The late Dr. James A. Sidey was a poet and humourist of remarkable powers, to whom fate assigned the routine work of a respected general practitioner. His "Irish Schoolmaster" if well sung, or still better if well recited, never fails to evoke demonstrative merriment; and his "Burnie that wins to the Sea," for the melody of its cadences and the liquid curves of its movement, is equal to the best lyric of the Ettrick Shepherd. Tennyson's "Brook" is not more picturesque, and the concluding lines—

"Till wi' lang fetchin' breath
Thro' the saut faem to death
Warstles the burnie that wins to the sea,"

recalls the lovely "fessas erroribus undas" of Ovid.

Among the other contributors to these "College Lays" the best is undoubtedly Dr. Andrew P. Aitken, whose "Flowrie," "Newhaven Fish Dinner," and "Our Kail Yard" flow in the happiest of metres to the most rollicking of tunes. The "Fish Dinner" particularly, as leading up to and culminating in the "remorse of a guilty stomach," is a peculiarly felicitous performance. A word of praise is also due to Dr. Batty Tuke's renderings and adaptations of German originals, which we much prefer to his "Heart's Autobiography," with its eccentric rhymes of "Ratke" and "dark, sirs," or "avail me" and "ovale," which look as if the accomplished alienist had been plagiarising from some verse-producing patient. Dr. Robert Lawson, Deputy Commissioner in Lunacy, suggests no such literary larceny, whilst warbling agreeably enough on "Modest Aims" and the "Song of the Spores." The volume, as a whole, is a welcome addition to the library of *vers de société* or, rather, *vers de circonstance*—doubly welcome for its demonstration that high medical proficiency and steady devotion to practice are not incompatible with the opportune indulgence of a genial humour conveyed in effective lyrical form.

Manual of Pathological Histology. By CORNIL and RANVIER. Second Edition. Translated by A. M. HART. Vol. II., Part 2. London: Smith, Elder, and Co. 1886.



WE are glad to find that this excellent translation of a justly celebrated work has been completed. At a time when pathological histology was in a fragmentary and somewhat chaotic state, MM. Cornil and Ranvier earned the gratitude of pathologists by their clear but ample descriptions, which did a great deal to stimulate study on the subject, and the influence of which is perceived in many contributions upon it from all quarters. The handy little volumes have given way to a more imposing work; and it is this second edition which the English student has now the advantage of perusing. The section before us comprises such important subjects as the Pathology of the Liver, Spleen, Genito-urinary Organs, and the Skin. All who are interested in the progress of science have only to compare these chapters with those of the first edition to be assured of the fact that the advance is real and extensive. Take, for instance, so well-known a topic as cirrhosis of the liver, the topographical anatomy of which has been greatly elucidated by Sabourin, whose instructive diagrams are reproduced in the text. The authors enter minutely into the changes observed in vessels and ducts in this disease. They discriminate several varieties—e.g., malarial, cardiac, hypertrophic (including biliary cirrhosis, fatty hypertrophic cirrhosis, and hypertrophic cirrhosis of diabetes), and atrophic. It is suggested that the last-named may sometimes be the outcome of the hypertrophic form—a doctrine which used to be almost universally taught. The complication of cirrhosis with adenoma receives detailed description. It is singular to find such eminent authorities stating that amyloid degeneration consists, even in its early stages, of a transformation of the liver cells; for we believe the contrary to be the case, and that the statement of Ziegler that "the liver cells are usually passive throughout the process, or at least they rarely become amyloid themselves," is the more correct. In their remarks on Bright's disease, the authors point out that the hard-and-fast distinction between parenchymatous and interstitial nephritis is one which cannot be sustained on anatomical or clinical grounds. They hold it to be more correct to say that the lesions are always combined with a predominance of one or the other. The classification adopted is that of—(1) diffuse nephritis; and (2) systematic nephritis, which includes the granular kidney. The pathological anatomy of the uterus and ovaries, especially of the former, is fuller than usual in text-books of this class, whilst the chapter devoted to diseases of the skin is of great value; it includes much new matter, and will doubtless be largely referred to by dermatologists.

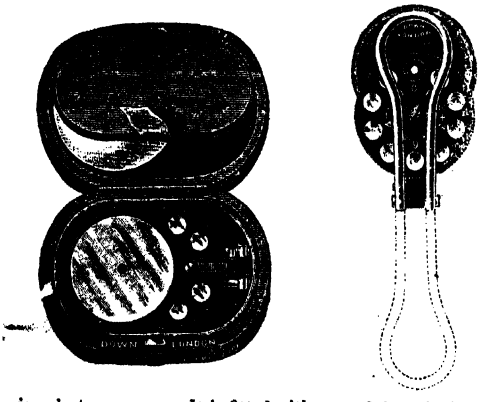
New Inventions.

A NEW CERVIX UTERI DILATOR.

DESPITE the conviction of such an eminent authority as Mr. Erichsen that surgical instruments have reached a state of perfection beyond which they are unlikely to advance, there are few thoughtful practitioners who will not for scores of years to come see the necessity of improvement and modification. For as the treatment of disease is being placed on more scientific bases, so must the art correspondingly advance; and although the armamentarium of the modern surgeon is astounding in magnitude, how short-lived are most of those instruments which but yesterday were considered marvels of ingenuity and effectiveness! How clumsy seem the contrivances of our forefathers. The advancement in surgical art has scarcely kept pace with the mechanism of other arts around us; and the very number of new instruments continually brought out, although in many cases showing more ingenuity attaching to ambition than to intrinsic worth, shows also that there are few instruments universally satisfactory, and few destined for a permanent existence. This is mostly true of special departments—notably, gynæcology and urethral surgery.

In connexion with the former, a good cervix uteri dilator would probably be the most needed of all instruments; and

those who resort most to the operation of dilatation of the cervical canal will be foremost in recognising the *raison d'être* of such an instrument. There are three contrivances at present used for the more or less complete dilatation of the uterine canal—(1) Dr. Barnes's bags, (2) Mr. Tait's dilators, and (3) tents; not to mention others—for instance, that of Dr. P. Smith and Dr. Jones's admirably shaped ones, which, however, are not intended for the condition now in question—viz., a full and complete dilatation. Without in any way trying to disparage Dr. Barnes's means, which are highly efficacious at certain stages of the process, we must refer to the very considerable difficulty attending their use at other stages, and assert that the means of introduction permits of great improvement. Mr. Tait's dilators require an amount of time in use, which cannot often be well spared. Tents are open to the same objection, and, besides, are said to be attended with risk. Moreover, both lack an important provision—viz., elastic force. After a tolerably



fair trial, and thinking over the matter with the help of Mr. Arnold, of Smithfield, we hereby offer an instrument which we think will be accepted by the profession as answering the requirements of a dilator more fully than those hitherto employed. It is simple in construction, easy of application, and has proved in our hands a promising contrivance. (See engravings.) It consists simply of an ordinary hollow sound, which sound can be used for general purposes, over the extremity of which elastic covers (A) of varying capacity slip on. These are easily inflated by the force-pump (B). The surgeon has complete command of the instrument, and may dilate slowly or rapidly as he likes. Mr. Arnold has got up the instrument neatly and well, and can, we are sure, supply it at a very reasonable price. Wetting the sound will make the bags slide on easily. The cut shows one of them *in situ* partly dilated. If any difficulty arise in the introduction of the first bag, we advise Dr. Smith's dilator to be first used; but this will scarcely be necessary. When the dilating process is commenced, the sound must be held firmly and gently in its place.

JAMES MACMUNN.
JOHN MACMUNN.

Finsbury-park, N., September, 1886.

NEW FORM OF OPHTHALMOSCOPE.

A MOST convenient and compact ophthalmoscope has been forwarded to us by Messrs. Down of St. Thomas's-street, Borough, S E, which they have made at the suggestion of Mr. Charles Oldham of Brighton. The instrument can easily be carried in the waistcoat-pocket, as the case which contains it is only 2½ in. by 1½ in., and its weight

is only two ounces. It is fitted with a revolving diaphragm containing five convex and four concave glasses — viz., +1, 2, 3, 4, and 6, and −1, 2, 4, and 8. The hole in the mirror is of reasonable size, and the movement of the diaphragm with the glass is exceedingly smooth and easy. The handle folds, but is quite steady. We have used it repeatedly, and have been quite satisfied with its action.

HARBOROW'S BRITISH WOOL UNDERCLOTHING.

THERE can be no question that from a health point of view wool is more suitable than any other material as the next covering of the skin. The manufacturers claim for the articles submitted to our notice that, having conducted experiments for some time past, they have secured command of a yarn which is perfect in its quality, and beautiful in finish, and that no colouring or deleterious dye of any kind has been employed. The material of the specimens sent to us is fine, soft, and elastic, and well adapted to furnish comfortable and healthy underclothing. The garments can be obtained at Harborow's, 15, Cockspur-street, S.W.

A NOVELTY IN SHOES.

MESSRS. DOUGLAS FRASER & SONS, of Arbroath, have submitted to our notice specimens of their jute and canvas shoes, which appear worthy of attention. They are suitable chiefly for house wear, but may be used with advantage out of doors in warm, dry weather, as they readily absorb perspiration and favour a firm foothold. Their remarkable cheapness renders them especially eligible for in-door workers, such as factory operatives, by whom, we understand, they are coming to be much in request in the north. The stout jute sole also will recommend these shoes to persons who suffer from coldness or tenderness of the feet.

THE "DESIDERATUM" THROAT COMPRESS.

THE throat compress sent us by Messrs. Marriott and Co. of Hastings, is a useful though luxurious application. It has all the properties necessary to constitute an efficient cold or tepid wet compress. It is hardly adapted for hot fomentations, as the compress has to be fixed by being slipped beneath strips of braid.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

WEDNESDAY, NOVEMBER 17TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

THE Minutes having been confirmed,

Dr. HERON WATSON moved: "That the Directors-General of the Medical Departments of the Army and Navy be respectfully requested to afford information on the statement of the degrees, diplomas, and licences of the candidates who presented themselves for examination for commissions in the medical staff of the army and navy respectively, which they have so kindly furnished to the General Medical Council in former years; whether a candidate holding several qualifications on the Medical Register is in these returns entered again and again according to the number of qualifications which he holds, or only under a single qualification; and if entered under more than one qualification, whether he is entered under each qualification he holds or only under two qualifications; and that in asking for this information it be explained to the Directors-General of the Army and Navy Medical Departments that the aim of the General Medical Council is to enable the Medical Council to enforce upon the different licensing bodies the important facts emerging from these reports bearing on the large number of candidates at these examinations who failed to pass, and more particularly as to the special subjects in which they were found deficient." The object of the motion was that the Council might be furnished with some further information to enable them to rightly interpret the tabular returns, which hitherto had not been very clear.

Sir DYCE DUCKWORTH seconded the motion, which was agreed to.

The following report was brought up from the Pharmacopœia Committee.

The Pharmacopœia Committee have to report to the Council that the first issue of 20,000 copies of the work have been disposed of, and that a reprint has been issued, consisting of 3000 copies, from the stereotyped plates, of which 730 have been already sold. The opportunity has been taken during reprinting of introducing into the body of the work such corrections as were found to be necessary. It may be noted that a list of these corrections can be had, without charge, from the Registrar, or from the publishers, by those who have purchased copies of the original issue. The Committee further report that they have arranged with Professor Attfield to prepare an annual report on the revision hereafter of the Pharmacopœia. The following is the plan submitted by Professor Attfield for carrying out this intention, and approved by the Committee:—"Broadly, a reporter should present (annually) to the Pharmacopœia Committee of the Council an abstract of the published researches and opinions which are or may become of importance in connexion with any future revision or edition of the Pharmacopœia—researches, opinions, &c., published by therapeutists, pharmacologists, pharmaceutical chemists and chemists-and-druggists, scientific and analytical chemists, and botanists. Secondly, while leaving purely original [illegible] changes to the workers in the various public

and private laboratories where such researches are conducted, a reporter should perform such experiments as may be necessary for the application of those original researches to the exact purposes of the Pharmacopœia. Thirdly, as regards suggested improvements of official processes, whether synthetical or analytical, a reporter should, when necessary, obtain experimental confirmation, or otherwise, of the suggestions before reporting them to the Committee. All this work, both literary and experimental, should be done regularly year by year; for the large and numerous areas of knowledge laid under contribution in revising a Pharmacopœia are fast getting too extensive to be properly investigated in any short period preceding the issue of a new Pharmacopœia. As for the classification of the annual reports, I think it should pretty much follow the division of matter in the Pharmacopœia itself. That is to say, questions of general construction and literary arrangement, and questions relating to weights and measures, to chemical and general nomenclature and notation, to the uniform disintegration of drugs, to temperature, &c., may be treated first. Then would follow the consideration of new remedies and compounds proposed for addition to the Pharmacopœia, and of old remedies and compounds proposed for omission from the Pharmacopœia. Any suggested alterations in the names of official articles and preparations would next be discussed. Suggested alterations respecting any of the alphabetically arranged articles or monographs in the text and appendix of the Pharmacopœia—nearly 1000 in number—would form the concluding portion, and indeed the bulk, of the annual reports—alterations relating to (*a*) leading names and associated synonyms, (*b*) definitions of articles of the materia medica, (*c*) descriptive characters of those articles, (*d*) mode of preparation of compounds, (*e*) characters and qualitative and quantitative tests of those compounds, (*f*) doses, and (*g*) additions to, omissions from, and alterations in, the cross references. There may also be some matters of importance to be considered which do not fall within either of the foregoing classes of subjects, as, for one example, the question as to whether or not any changes—and, if any, what changes—can be effected in a future British Pharmacopœia to better adapt it to Indian and colonial requirements. The annual reports should, of course, contain clear references to all sources of information; so that the Committee, future editors, and all persons interested in the subject could readily refer to all data. Finally, the hands of the reporter or reporters would be strengthened, and the reports would come before the Committee with greater weight, if draft reports, before presentation, were carefully considered by the three editors of the British Pharmacopœia, 1885, who for this purpose should be regarded as consultants. The designation of a reporter would be, probably, 'Reporter on the British Pharmacopœia to the Medical Council,' the instructions to any such officer being, I presume, to report annually, on some such lines as the foregoing, to the Pharmacopœia Committee of the Council."

RICHARD QUAIN, M.D., Chairman.

Dr. QUAIN moved that the report be received, entered on the Minutes, and adopted. He heartily congratulated the Council on the success which had attended the work of the Committee. It had a most extensive circulation. It had been subjected to some very rigid criticism, and though they might complain of some of the criticism being hypercriticism, the work would be none the worse. Careful notes had been taken of every word and criticism that had been passed, and would be available for revision. He also congratulated the Council on the very satisfactory report presented by Professor Attfield.

Dr. A. SMITH seconded the resolution, which was agreed to.

Dr. LYONS brought forward the subject of the medical examination of women, which was considered in the absence of strangers.

Mr. MARSHALL moved, "That the Executive Committee be requested and empowered to take such steps as may be required in order that the provisions of the Medical Act, 1886, concerning the registration of diplomas or certificates in Sanitary Science, may forthwith be carried out." He thought that, considering the amount of business probably coming before the Council, it would be desirable to ask the Executive Committee to carry out the duty named in the resolution. It was mainly an administrative matter, involving no inquiry except one—viz., whether particular diplomas deserved recognition in the Register. It was certainly desirable that the diplomas should assume a common form in the Register.

Mr. SIMON seconded the motion.

Dr. QUAIN hoped that the Council would express an opinion on the proper amount of fee for registration.

Dr. A. SMITH said that the holders of the diplomas would be grievously disappointed if they did not appear in the Register next year. As to the amount of the fee, he thought that as the diploma was a supplemental one 5*s.* would be a sufficient fee.

Mr. MACNAMARA, while thinking that the matter might be referred to the Executive Committee, was of opinion that there were some points on which an opinion ought to be expressed by the Council—viz., as to where the diplomas should be registered, what the title should be, and what should be the amount of the fee. As to the place of registration, it should be remembered that the different Branch Councils had separate sources of income, and therefore the fees, however small, should be paid to the Branch Council in that division of the kingdom from which the qualification was obtained. As to the title, it would certainly be desirable that there should be a common [illegible] desire that the place whence the qualification was obtained should distinctly appear on the Register. The question of the amount of the fees should not be left to the Executive Committee, but should be decided by the Council itself. His own opinion was that the fee should be a moderate one; and that if the diploma was registered at the same time as the other qualifications, there should be no additional charge beyond the £5.

Sir DYCE DUCKWORTH said this was a matter which the Executive Committee might fairly be trusted to determine.

Dr. BANKS concurred. He did not consider that the question of the name was so important. The Council should decide on the name which was to appear on the Register and then it was not of very much importance if there was a difference in the name adopted by the qualifying bodies.

Mr. TEALE asked whether the Council had power when one form of title was brought forward to put another form of title on the Register.

Mr. SIMON said it was not a question of the Council inventing a title, but of using the title which had been given by law. He thoroughly agreed with the sentiment expressed against troubling themselves needlessly with trumpery distinctions. Let them use the broad language of the statute. He thought that the term "Public Health" was most convenient. Let them use that, and if each body liked to have a title extending to three, six, or ten lines, or that would cover three brass plates, it might amuse them and would hurt no one.

Dr. QUAIN asked Mr. Marshall if he would accept as a rider that the fee be 5*s.* for the insertion of this diploma.

Mr. MARSHALL replied that the fact that 5*s.* was the existing fee would be a guide to the Committee in fixing the fee for the insertion of this new qualification.

Dr. HERON WATSON thought the course suggested was a safe one, since he believed the Committee would in the first instance take the opinion of counsel in regard to the exact meaning of Clause 21 of the new Act. He was a little in doubt as to the prudence of their adopting the second resolution of which Mr. Marshall had given notice, which stated that "the Council would view with great satisfaction the adoption of a common form of title by the several medical authorities which confer them." He hoped that the subject would be generally remitted to the Executive Committee.

The resolution was agreed to.

Mr. MARSHALL withdrew the next resolution on the subject, of which he had given notice (urging the adoption of a common form of title) on the ground of the legal doubts which surrounded the subject.

Mr. MACNAMARA asked what steps had been taken by the Privy Council or the General Medical Council to decide whether the several diplomas deserved recognition in the Medical Register.

The PRESIDENT said that the General Medical Council had certainly taken no such steps, and to the best of his belief the Privy Council had not done so.

Dr. MCVAIL moved, "That the resolution passed by the General Medical Council on May 22nd, 1885—'That the course of medical study after registration should occupy at least five years, if the subjects of elementary physics, chemistry, and biology are included in that period, or at least four years if a satisfactory examination in these subjects has been passed previous to registration,'—be made compulsory in the case of all students who shall be registered on and after January 1st, 1887; and that the word 'biology' in the resolution shall be held to include zoology or natural history and botany." He thought the Council had taken a great step in advance in passing the resolution mentioned in his (Dr. McVail's) motion, and he had hoped that the universities in Scotland would carry out the recommendations therein contained. The specified time in those universities was still four years—four winters and three summers. The custom was for the student to begin in May, beginning a summer session, and then take botany and zoology; taking chemistry in the following winter. Indeed, during the first winter and first summer session the attention of the student was almost exclusively occupied with subjects that bore only in a somewhat indirect manner on his medical course. Even if the student passed the first examination successfully, the time for professional training was diminished; but a considerable number (about 40 per cent.) did not pass the first examination, and then they had to carry on the subjects into subsequent sessions. Then, again, the subjects of hygiene and mental disease were required in the latter part of the course,

which still further shortened the period available for the subjects of anatomy, physiology, surgery, midwifery, and forensic medicine. He maintained that the subjects of botany, zoology, and chemistry should be taken before the study of medicine, and that the resolution of the Council ought to be enforced.

Dr. MITCHELL BANKS, in seconding the resolution, said the first point to be considered was, what was best in the interests of the public in general. The supply of candidates was quite equal to the demand, and it was not necessary that the licensing bodies should offer any inducements. It was their business not to make the standard of education as light as possible, but to raise it. No doubt there were men who could do all in four years that was proposed to be done in five, and also that many poor men would be prevented from entering the profession if they were obliged to stay for five years. But the question was, were the interests of a comparatively small number of men to be set against the interests of the great mass of medical students? He thought not. It was of advantage to the students themselves, because the process of passing the curriculum of five years in four was only carried on at a great cost of brain power, and might give rise to future mischief. He believed that it was not possible to carry out such a system.

Dr. BANKS said he had long advocated the principle that five years ought to be the minimum devoted to medical study. In the university which he represented there were four years of exclusive medical study. The elementary subjects must be learned in the first year, and then the four years were exclusively for medical study.

Dr. MATTHEWS DUNCAN, while concurring in the proposal, said there was one point which Dr. McVail had forgotten, and which was the cardinal point in the matter—viz., that the Scotch universities could not do it. The recommendations were only made last year, and, so far as he knew, the Scotch universities were very anxious to adopt them.

Dr. HUMPHRY pointed out that the Council had already passed a resolution in accordance with Dr. McVail's views, but they were now asked to do that which they had no power to do do—namely, to make it "compulsory."

Dr. MCVAIL said he would withdraw the word "compulsory," and would put the resolution in the form of a recommendation.

Dr. STRUTHERS said the question was discussed very elaborately last year, and he was unwilling it should be raised again. He agreed in the abstract that the course of study should be as long as possible, but, as a teacher of long experience, he thought the fifth year should be put at the end of the curriculum, and not form part of the curriculum.

Sir W. GULL thought it would be better for the Council to wait a little longer before passing such a resolution.

Dr. HERON WATSON said that the Council had already given a distinct declaration on the subject. The motion passed by the Council was undoubtedly so framed as to cover the case of students like those of Trinity College, Dublin, whose studies did not follow quite the same course as that adopted in most other schools. He hoped that the modified motion of Dr. McVail would be agreed to. It would not interfere with the state of things existing in Ireland.

Mr. COLLINS considered that the first year spent by students with an apothecary was in many cases the most important part of medical education. For general practitioners, at any rate, it was far more important than studying such a subject as zoology. Many eminent men in Dublin had expressed to him their belief that the very best way in which a young man could commence was in a respectable apothecary's shop, where he might every day see cases of measles, whooping-cough, scarlatina, bronchitis, and the like, thus learning the rudiments of the profession as well as the rudiments of pharmacy, and also learning how to keep his books as a general practitioner.

Dr. MCVAIL, in reply, said the question for the Council to consider was whether the resolution was a good or a bad one. If it was a good one, it could not come into operation too soon. Had the universities specially affected done anything in the way of preparing to carry out the recommendation of the Council? If such steps had been taken in Aberdeen Dr. Struthers would have mentioned it, but he had not done so. If the Universities of Glasgow, St. Andrews, and Edinburgh had taken any steps, the Council would have been informed with reference to them, but no such information had been given. The fact that nothing had been done in the required direction was a sufficient reason for urging both universities and corporations to begin.

The PRESIDENT, in putting the amendment of the "previous question," adopted the method of submitting the question in the House of Commons, putting from the chair "that the question be now put," and explaining that those who supported the amendment would vote in the negative. On a show of hands being taken, the President declared the "previous question" carried. Several members protested that they had voted under a misapprehension, and after some considerable discussion on the peculiarities of the "previous question," and the various modes of putting it, the President said that there had evidently been a misapprehension on the part of some members, and in order to get over the difficulty he would take a distinct vote, aye or no, upon Dr. McVail's modified resolution—viz., "That it be a recommendation to the licensing bodies to give effect as soon as possible to the resolution of May 22nd, 1885, as follows:—'That the course of medical study after registration should occupy at least five years, if the subjects of elementary physics, chemistry, and biology are included in that period, or at least four years if a satisfactory examination in these subjects has been passed previous to registration be made compulsory in the case of all students who shall be registered on and after the 1st January, 1887; and that the word biology in the resolution shall be held to include zoology or natural history and botany.'" The resolution was then put and declared to be carried, 11 members voting for it and 7 against. On the names being taken down, however, the numbers were declared to be—for, 10; against, 3.

THURSDAY, NOVEMBER 18TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

On the customary motion for the confirmation of the Minutes, the Council spent some time in discussing the mysteries and perplexities of the "previous question," which had been moved on Wednesday, but of which no entry appeared on the Minutes. It was finally resolved that an entry should be made simply recording the fact that a vote was first taken on the previous question, and that some of the members having voted under a misapprehension, the sense of the members was taken on the original motion instead.

The Council then proceeded to the consideration of dental business.

Mr. FARRER (the solicitor to the Council) presented a report from the Dental Committee with reference to the case of Thomas Maden, the entry of whose name in the Dental Register was said to have been obtained fraudulently and incorrectly. The practitioner was alleged to have been articled to Samuel Haworth, dentist, of Mill-end, New Church, near Manchester, the articles expiring on Jan. 28th 1879. Maden was born on Oct. 4th, 1865, and was therefore but eleven years and four months old at the time he was alleged to have been articled, and thirteen years and four months old at the expiration of the articles. During the greater part of the two years of his alleged articles he attended as a scholar at a national day-school, and for another portion of the time he was working at a cotton manufacturer's. Mr. Farrer pointed out that under the Dentists Act the Council had power to erase a name the entry of which had been fraudulently and incorrectly obtained, and that the report of a committee of the Council on the facts of the case might be deemed conclusive for the purpose of exercising such power. It was the opinion of Mr. Muir Mackenzie that the name could be erased without citing the practitioner. Mr. Maden's father, a Yorkshire labourer had been applied to on the subject, and his simple answer was, "Let them as put it on take it off." (Laughter.)

The Council deliberated upon the case in private, and passed a resolution directing Mr. Maden's name and qualification to be removed from the Register.

Dr. BANKS moved: "That, subject to legal opinion, the title of Diplomate in Sanitary Science be adopted as the heading in the Medical Register under which all practitioners duly certified in sanitary science may be placed, the sources of their titles being designated in each case." He thought that the name "diplomate" was the most suitable for the holders of the degrees in question. If the sources of the titles were designated in every case, there could be no objection on the part of those who held diplomas conferred by

[redacted] seconded the motion. The matter

was one which had excited a good deal of attention, and a great desire had been expressed that a uniformity of nomenclature should be adopted. The names given to the diplomas by the different bodies conferring them were very various, and it would be difficult to get all the bodies to adopt a similar title; but the Council might have a general heading for them in the Register.

Mr. TEALE supported the motion.

Mr. SIMON agreed with the principle of the motion; but he ventured to suggest that "diplomate" was not an English word, and he thought that "holder of diploma" would be better. The question of nomenclature ought to be left to the Executive Committee.

Dr. BANKS said he was willing to accept the term "holder of diploma."

Mr. SIMON said the question would next arise whether the diplomas should be in "State Medicine," "Public Health," or "Sanitary Science." The three terms could not be regarded as exactly equivalent. There was also the question of whether a diploma was worthy to be registered. Such diplomas would be mainly required as qualifications for public office, and that might be a test in deciding the question of registrability.

Sir DYCE DUCKWORTH said that it was the opinion of the Society of Medical Men qualified in Sanitary Science that "Diploma in Public Health" would be the most suitable title.

Dr. HUMPHRY thought that the Council had no right to alter in the Register the titles given to the diplomas by the different bodies conferring them. The diplomas should be entered under the titles in which they were given.

Dr. BANKS said he would alter his motion to "Holder of Diploma in Public Health."

Sir WM. GULL said it was incumbent on the Council to follow the Act, and designate the diplomas by the titles given by the bodies conferring them.

Dr. HERON WATSON said that the question had been already decided by the motion passed on the previous day referring the matter to the Executive Committee. The language of the new Act was peculiar. The words were "if such diploma appears to the Privy Council or to the General Council to deserve recognition in the Register." There were difficulties in the way, and he thought that legal opinion should be taken in the matter. He moved as an amendment: "That this matter be referred to the Executive Committee along with the whole questions emerging out of the Interpretation Clause 21 of the Medical Act (1866), with the sanction of the Council to take a legal opinion upon any matter connected with it."

Mr. MARSHALL seconded the amendment. There was so much uncertainty in the matter that he thought the Council was not prepared to act at once in the way suggested. He thought that under all the circumstances the Council would be compelled to register the titles under the names given to them by the bodies. Up to the present time 235 of such qualifications had been given; 125 had been given under the term "certificate," 28 under the term "diploma," and only 3 under the term "qualification"; 60 employed the term "public health"; 142, "sanitary science"; 6, "hygiene"; and 37, "State medicine."

Dr. BANKS said that under the circumstances he would withdraw his resolution, being quite willing that the whole matter should be referred to the Executive Committee.

The resolution was accordingly withdrawn.

A Provisional Report was presented by the Visitation of Examinations Committee.

Mr. MARSHALL said that the subject was so extensive that the Committee had only been able to present a provisional report. His idea had been to bring up a complete report, which should be worthy of the money that had been expended (£2000 or £3000) in collecting the materials. He had devoted a great deal of time to the subject, and had circulated a draft report confidentially among the members of the Council, asking for suggestions and improvements. Some of the members had complied with his request, but others had not, and he felt that it would be premature to present his report during the present sitting of the Council. The object of the report was not to correct immediately any abuses or suggest any immediate improvements. If the Committee had been ordered to sit upon the conduct of certain universities, and if they were anxious to have the decision of the Council upon the matter, it would be a different thing. The object of the Committee however was to take the reports of the visitors, [illegible] concerned and endeavour [illegible] and materials as would be useful for all time. The amount of material was very great, and it required to be very accurately sifted before it was presented to the Council.

Sir WILLIAM GULL said he was not present at the last meeting of the Council, or he should have remarked on the ignorance displayed by the visitors in their report with reference to the London University. He was glad that Mr. Marshall had agreed that the consideration of the subject should be referred to a future meeting. The object was to ascertain what amount of knowledge all students possessed, and not how many lectures they had attended.

Mr. TEALE thought the matter ought not to be gone into prematurely. Between the present sitting and the next the Council would have the opportunity of studying the conclusions presented by the Committee, and would be in a much better position to come to some decision with respect to them.

Dr. MCVAIL thought that the sooner things could be set right the better, and if the matter were allowed to stand over, he hoped it would be with the distinct understanding that the report should be ready for the next meeting of the Council. He should have a good deal to say with regard to the report on the university to which he belonged.

Dr. BANKS said that the report upon Dublin University was in some respects a most unfair one; he did not, however, wish to imply that there had been any wilful misrepresentation. There had been certainly a want of care and attention in regard to some of the statements made.

Dr. HERON WATSON objected to the entry of the provisional report upon the Minutes, which, he said, would have the effect of making it public before any discussion could take place. If the report were entered upon the Minutes, the only proper course would be to proceed at once with the discussion. It would be better, however, that the whole matter should be first well sifted, which, it appeared, could not be done during the present sittings of the Council.

Mr. MARSHALL thought that the general principles embodied in the Provisional Report, in the nature of "conclusions," might be at once made public, no censure being passed upon any member of the body. With regard to the full Draft Report the case was different.

Dr. HERON WATSON said the conclusions were founded upon the report.

Dr. STRUTHERS said that the visitors to the London University were men of the very highest eminence, and the remarks that had been made with reference to them were, he thought, irregular and improper.

Sir WILLIAM GULL said that at the last meeting of the Council, when the matter was discussed, Dr. Quain did not, as he thought, sufficiently defend the position of the London University, and that was the reason why he (Sir William Gull) had referred to the matter.

Mr. MACNAMARA said that, as one of the visitors, he was quite willing to submit to any imputation that might be thrown upon him for crass ignorance; indeed, he accepted it as a kind of commendation coming from the lips of Sir William Gull. There was an old legal maxim, "When you have a bad case, abuse the opposite attorney," and that was the course adopted by Sir William Gull. The visitors were quite prepared to stand by every statement that they had made, and they might perhaps have an opportunity of convincing Sir William Gull of the accuracy of their statements, many of which were derived from the records of the London University itself. He was quite sure that Sir William Gull would regret having charged men of distinction with crass ignorance.

Sir WILLIAM GULL.—I did not say crass ignorance; I said ignorance. (Laughter.)

Mr. MACNAMARA.—"*C'est le ton qui fait la musique.*" With regard to the proposal of Mr. Marshall, there could be no doubt that it was desirable that the consideration of the subject should be postponed until a complete and accurate report could be presented.

After some further discussion the motion and amendment were both withdrawn, and the following entry was ordered to be made in the Minutes:—"The Committee on Visitation of Examinations stated that they had prepared a provisional report, and they were requested to continue their labours till the next meeting of the Council."

Dr. HERON WATSON presented the following report from the Visitation of Schools Committee:—

"The Committee on Visitation of Schools appointed on June 4th, 1886, [illegible] enabled [illegible]ain provisionally to report that in conformity with their [illegible]epor[illegible] of June 7th, 1886 (page 92 of Minutes of Council for June

9th, 1886), adopted by the Council on June 10th, the proposed letters (Minutes, pp. 93-94) to (1) each of the licensing bodies, and (2) to the several medical schools, and to individual teachers not connected with schools whose courses qualify for the curricula of the various licensing bodies in the United Kingdom, were despatched to each of these bodies and individuals on the 25th of June; that replies have been received in answer to these circular letters from all the licensing bodies, from medical schools willing to receive visitors, from hospitals stating that no medical school exists in connexion with them, from private lecturers and extra-mural schools willing to receive visitors, and from the school of St. Bartholomew's Hospital, respectfully declining to receive an official visitation from the Medical Council. Your Committee further beg to report that, having considered the means of arranging for the proposed visitation, they are of opinion that, before developing a scheme of visitation, it may be well to place the matter before the Branch Councils, with the request that they will take the method of conducting these visitations into their consideration and furnish reports thereon to the General Medical Council. Your Committee further beg to suggest that counsel's opinion be obtained upon the legality of an expenditure of any part of the funds of the General Medical Council on the visitation of schools.

Nov. 17th, 1886. P. HERON WATSON, Chairman.

It would be observed, he said, that there was but one body that had thrown any obstacle in the way of the proposed visitation. He proposed, "That the report of the Visitation of Schools Committee be received and entered on the Minutes, and that the suggestions therein contained be approved; that the reports from the Branch Councils on a scheme or schemes of visitation, as well as the opinion of counsel on the question of the application of the funds and the expenses of the visitation of schools, be remitted again to the Committee, with a direction to bring up a further report at the next meeting of the Council."

Sir WILLIAM GULL seconded the motion, and said he hoped that Dr. Heron Watson would press the matter. He had hoped that a great institution like St. Bartholomew's Hospital would set an example to the whole of the medical world and open its doors to a full inquiry into all the matters of education. He did not say that there was any deficiency, but at present their doors were shut. If he were asked to give a reason, he might say something very severe. He was challenged to say it, and he would therefore say that in the year 1856 he was a member of the University of London and on the Senate, and he then proposed that no degree should be given in England unless the man was examined at the bedside clinically. He canvassed all the hospitals personally, and St. Bartholomew's stood out against him for some time.

Sir DYCE DUCKWORTH asked that the reply received from St. Bartholomew's Hospital might be read.

The letter was read, and was as follows:—"In reply to your letter, I am desired to say that the medical officers and lecturers of St. Bartholomew's school are not satisfied as to the public utility of the visitation of schools by the General Medical Council; they must therefore respectfully decline to receive an official visitation from the Medical Council, but desire to add that the school of St. Bartholomew's may be seen by any member *(sic)* of the Council who wished to [illegible] themselves about it, whenever it suits them to come, and I forward a year-book which contains the names of the teachers, the hours of teaching, and other details of the work of the school." The letter was signed by Dr. Norman Moore, the secretary of the school.

Dr. HERON WATSON observed that the letter was rather obscurely worded.

The discussion on Dr. Heron Watson's motion was adjourned at the rising of the Council.

FRIDAY, NOVEMBER 19TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

The adjourned debate on the motion by Dr. Heron Watson with reference to the provisional report of the Visitation of Schools Committee, was resumed.

Mr. MACNAMARA thought that the first thing to be done was to take counsel's opinion as to the application of funds to the purpose in question. Then it would be necessary to consider what the amount of the expenditure would be. Each school would have to be visited in both winter and summer in order that the visitation might be a complete one; the expenditure would therefore be formidable; and it was a serious question whether the funds at the disposal of the Council would be sufficient. Their funds, he thought, would soon be exhausted if even one such visitation were attempted, and he doubted whether the game would be worth the candle. The great point to ascertain was whether the schools were discharging their duty, and the onus of [illegible] that might be thrown upon the colleges receiving certificates.

Dr. DUNCAN deprecated any check being placed upon the progress of the visitation of schools. Mr. Macnamara's objections to such visitations might be raised with still more force against the visitation of examinations. It might or might not be an expensive affair, but he did not know how the money could be better devoted than to the proposed inquiry. The Council was specially charged with the subject of medical education, and that was of much more importance than medical examination.

Dr. QUAIN said that the Council had no authority to interfere with the course of education. It was impossible that it could do what was suggested, even if it had treble its present amount of funds. It would be sufficient for the Council to direct the attention of the licensing bodies to the importance of seeing how the schools were conducted.

Mr. SIMON said that the merits of education and examination were often differently estimated by critics according as they were educators or examiners, and that was perhaps to some extent illustrated by the remarks of Dr. Duncan. He agreed that it was extremely important to see that the education in the schools was efficient, but how was it to be secured? The Council was not in a position to secure it except indirectly. The responsibility rested on the different examining bodies, and in so far as the Council interfered with them it diminished that responsibility.

Dr. HERON WATSON, in reply, said that all that the motion asked the Council to do was to approve of the suggestions contained in the Provisional Report, and to remit the reports from the Branch Councils to the Committee with a direction to bring up a further report. The Committee had not developed any scheme at present, it only suggested that the questions should be referred to the Branch Councils for consideration. The question of expense would depend upon the reports received from the Branch Councils. He hoped that the Committee might be allowed to continue its duties, and that the various reports received might be brought before the Council at an early period.

The motion was then put, and carried by a considerable majority.

The perplexing subject of "the previous question" was again considered by the Council, on a motion of Mr. MARSHALL, seconded by Mr. SIMON—namely: "When in reference to any motion before the Council, a member moves 'the previous question,' the form of the motion put from the chair shall be: 'That the Council (instead of proceeding to vote on the question originally proposed) do pass to the next order of the day.'"

Dr. HUMPHRY maintained that "the previous question was well understood, and that there was no necessity for any alteration.

Dr. M. DUNCAN moved "the previous question." (Much laughter.)

After some discussion on the subject, the PRESIDENT put Dr. Duncan's amendment of "the previous question" in the usual form: "That the question be now put," explaining that those who supported the question would vote in the negative.

A show of hands was taken, and the amendment, "That the question be put," was declared to be carried.

Mr. Marshall's proposal for a new standing order was then put and agreed to.

Dr. MCVAIL moved,—"That it be a recommendation to the licensing bodies that, in admitting candidates to professional examinations, care be taken that attendance on courses of study prescribed for any second professional examination shall qualify only if made *after* the first examination has been passed, and generally that attendance prescribed for any subsequent examination must be made after passing the immediately preceding examination." To the average student, he said, it would be a dreadful mental strain to keep up all the subjects to the end of his curriculum, and to pass them all at once. All the bodies, therefore, now divided the examinations into at least two parts, some into three, and some into four. That worked well in the case of the average student, who was able to pass the examinations exactly when they ought to be passed. But when a man failed to pass his first examination, if he still continued his studies and took classes leading up to the second examination, all the time he was preparing for the second examination he was also working for the first, and he could not give his undivided [illegible] the work of the senior examination. [illegible] men failed in the first examination, did not at once

set about working up for that examination, but took classes in the next session as if they had passed the first examination, hoping to scramble through both examinations together. The resolution would inflict no injury on the student who did his work properly, and it would enormously aid the weaker students, or those who had not given proper attention to the early subjects.

MR. MACNAMARA, in seconding the motion, said that the principle advocated by Dr. McVail had been for some years in force in the Royal College of Surgeons in Ireland.

MR. TEALE thought that the proposal was a retrogressive one. The Council was disinclined to pass minute regulations like that brought forward, and on that account the motion was objectionable. It would, besides, inflict a hardship on some students who failed to pass examinations from causes for which they were not altogether responsible.

DR. BANKS said it would be a great pity to interfere in the way suggested with the course of education.

DR. W. M. BANKS would be unwilling to see anything done that would be unfair or cruel to medical students. He sympathised very much with Dr. McVail in what he had stated. There were, however, cases in which a student very nearly attained the amount of knowledge required to pass, and only just failed to pass; and in such a case it would be a great hardship to put the student back as proposed.

DR. HERON WATSON also thought that a hardship would be felt by many students if the proposed regulation were adopted.

DR. STRUTHERS said that students were often found attending lectures as a matter of form, while they were giving all their attention to other subjects in which they had previously failed. Most of the rejections referred to were due to idleness; really stupid students were generally stopped at the preliminary examinations. A certain proportion of students were always idle, but if they were rejected they were able to go at double pace the next year, and an extra year's study would be too severe a penalty in such a case. He thought it would be a better plan to lay down a definite interval—say two years—between the early examination and the final one. He ventured to suggest that Dr. McVail's proposal would be unworkable, and hoped that he would withdraw it.

SIR DYCE DUCKWORTH also thought that the recommendation would be unworkable, and its adoption would therefore be very undesirable.

DR. MCVAIL said he was content to have introduced the subject, and would be willing to withdraw it if Mr. Macnamara consented.

MR. MACNAMARA declined to consent to the withdrawal of the motion.

MR. SIMON thought that this was specially a case in which "the previous question" or a proposal to "pass to the next order of the day" might be advantageously moved. The principle of the motion was right, but it would be undesirable to adopt at the present time an additional regulation.

DR. PETTIGREW said he would second "the previous question" moved by Dr. Heron Watson.

THE PRESIDENT said he should upon that question (according to the standing order just passed) put the motion —"That the Council do pass to the next order of the day."

MR. MACNAMARA regretted that the Council had not the courage of their opinions. If Dr. Heron Watson's motion were passed the subject would be shelved without any expression of opinion on the subject, and he protested against that course being adopted.

DR. HERON WATSON'S amendment of "the previous question" was then put and agreed to—viz., "That the Council do pass to the next order of the day."

DR. STRUTHERS moved: "That it be a recommendation to the licensing bodies to give effect as soon as possible to the General Council's resolution of May 22nd, 1885, as follows—'That at least four winter and three summer sessions should be passed at a school or schools recognised by any of the licensing bodies mentioned in Schedule A of the Medical Act.'" He said that as the Council had passed the motion proposed on a previous day by Dr. McVail, he thought it was still more necessary to pass the motion which he now proposed, seeing that the recommendation of the Council referred to in it was one of extreme importance. There were some bodies like that represented by Dr. McVail that had not adopted the recommendation. The bodies which he represented had long [illegible] four winter and three summer

DR. PETTIGREW [illegible]

DR. MCVAIL supported the motion. He thought that it had been included in the motion which he had previously brought forward, but if not, he certainly desired that the same course should be followed with reference to the recommendation as to four winter and three summer sessions.

The motion was agreed to, ten members voting in its favour.

A communication was received from the Scotch Branch Council recommending the recognition of the preliminary examinations of the Ontario College of Physicians and Surgeons. It was stated that the examinations were recognised by the Canadian Universities, and it was also stated in a memorandum by the General Registrar that "The Trinity Medical School of Toronto *advises* its students before entering to become matriculated students of the Medical Council of Ontario, and become so matriculated students must pass either the late High School Intermediate Examination or the third-class Non-Professional Examination with Latin. These examinations include the following *compulsory* subjects:—English Grammar, English Literature, Composition, Dictation, History and Geography, Arithmetic, Algebra, Euclid, Latin (which may be taken separately); and as an *optional* subject, Elementary Mechanics."

DR. STRUTHERS proposed that the preliminary examinations be accepted, the certificates to include all subjects required by the Council.

DR. HERON WATSON seconded the motion.

MR. SIMON said it was questionable whether the Council should accept preliminary examinations by a medical body in Ontario. It would be initiating a new policy.

DR. DUNCAN said that there was no preliminary examination by the College of Physicians in Edinburgh.

DR. HERON WATSON said that the preliminary examinations of other similar bodies had already been admitted, and it was unintelligible that the present application should be refused.

The motion was agreed to.

DR. HERON WATSON asked whether a representation to Her Majesty in Council with regard to Clause 21 of the Medical Act, 1886, be or be not one of those duties which it is *ultra vires* of the General Medical Council to delegate to the Executive Committee appointed out of their own body in accordance with the provisions of Section 9 of the Medical Act, 1858.

THE PRESIDENT stated that the question was one of legal construction, and he would take counsel's opinion upon it.

The Council then adjourned.

SATURDAY, NOVEMBER 20TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

On the motion of DR. QUAIN, seconded by DR. BANKS, Mr. Marshall was added to the Dental Committee.

DR. QUAIN moved, "That the attention of the Council be directed to the resolution adopted on April 21st, 1883, as follows (Minutes, vol. xx, p. 71):—'That the Council record on its Minutes, for the information of those whom it may concern, that charges of gross misconduct in the employment of unqualified assistants, and charges of dishonest collusion with unqualified practitioners in respect of the signing of medical certificates required for the purposes of any law or lawful contract, are, if brought before the Council, regarded by the Council as charges of infamous conduct under the Medical Act.' That steps be taken with a view of making public the above resolution." He said that the resolution referred to had been practically a dead letter, and he thought that publicity should be given to it.

DR. HERON WATSON seconded the motion, which was agreed to.

On the motion of MR. MARSHALL, seconded by MR. SIMON, the scheme for constituting an Examining Board in Ireland by the King and Queen's College of Physicians and Royal College of Surgeons in Ireland was received and ordered to be entered on the Minutes.

DR. A. SMITH moved that the scheme be sanctioned by the Council. He said that the scheme was on the same lines as that of the Conjoint Board in England, and a great deal of time had been bestowed on its consideration. He hoped, therefore, the sanction of the Council would be given to it.

MR. MACNAMARA seconded the motion.

MR. SIMON said the Council was now an expiring body ("No, no"); not as a corporation, but as regarded the [illegible] The Corporation, of which it consisted, they were [illegible] condemned set [illegible] ples (laughter), and they were not really in a

position to pass a measure of the importance of the one now proposed. Technically they could do so, but morally speaking they could not at the last minute of their existence adopt a revolutionary measure. Within six weeks the representatives of the profession introduced by the new Act would be entitled to express an opinion on the subject, and in the meantime the Council ought not to settle a question of such immense importance. He was not an indiscriminate eulogist of the mode of election provided in the Act, but it was the law of the land, and they were bound to obey it. If the scheme were adopted, the Apothecaries' Hall of Ireland would be excluded. The Medical Council could under those circumstances appoint assistant examiners; and in that case there would be in Ireland a competing body with the two Colleges, which would be a serious departure from what the Council had hitherto desired. The question was an extremely grave one, and required serious consideration. He did not express any disapproval of the scheme, but he would move, "That the proposal of the Irish Royal Colleges to constitute an examining board in Ireland under Section 19 of the Medical Act, 1858, be not considered by the Council until after Jan. 1st, 1887."

Sir DYCE DUCKWORTH supported the amendment. The question, he said, constituted a pivot, upon which a still larger question would turn, as to which there had been a good deal of agitation. It would be much better discussed in the modified Council of the future. He did not agree with Mr. Simon in his description of the existing Council. He never approved of the introduction of new blood, because he never considered it to be necessary, since the existing members represented the general practititioners throughout the country. The new members introduced would only be a part of the Council; but under the circumstances, so large a scheme as that proposed ought not to be entered into until after those new members had been elected.

Dr. BANKS said that the question was a most momentous one, and on the last day of their sitting it would be highly inexpedient to enter upon its discussion.

Dr. QUAIN said that the question was not a new one. It had been previously discussed, and he saw no reason for the postponement of the subject, except that that was the last day of the sitting of the Council. That was perhaps a sufficient reason for the postponement, and he would therefore not oppose it. As to the scheme itself, he wished to call attention to Clause 15, which contained the extraordinary provision that "the Committee of Management shall annually elect a secretary, the remuneration of whose services shall be *shared* equally by the Colleges." (Laughter.)

Dr. HUMPHRY said he did not think that the Council was prepared under the present circumstances to give full consideration to the scheme. There were some points in it that would require explanation and modification before it could be finally accepted. It would therefore be better to postpone the matter till after Jan. 1st, as proposed in the amendment. It would be remembered that after June 1st no incomplete qualification could be accepted, and steps therefore should be taken to settle the question finally before that date. That ought to be done at a meeting early in the year.

Mr. MACNAMARA said that the arguments that had been adduced were really in favour of the present consideration of the scheme of the Council. If the Council met in January to discuss the subject, the scheme would probably be remitted to the Colleges for reconsideration, and it was hardly likely that the President would summon another meeting of the Council before the month of June, by which time only complete qualifications would be accepted. In that case the College of Physicians and College of Surgeons would be virtually disfranchised. As to the present being the last day of the sittings of the Council, that was the fault of the chairman of the Business Committee, who might have had the subject brought forward on the first day instead of the last. He appealed to the members of the Council to discuss the subject, even though it should require another day's sitting.

Dr. QUAIN said that no body could be disqualified except by the Privy Council.

Dr. A. SMITH supported the amendment. The matter might be fully discussed at an early meeting next year, and that would no doubt be the proper course to adopt. When the time came the College of Physicians in Ireland would have some strong observations to make on the subject.

Mr. COLLINS said that the scheme presented had been reluctantly agreed to by the College of Surgeons [illegible] communication had been received from that College stating the Council regretted that their efforts to secure the co-operation of Apothecaries' Hall in the projected Conjoint Scheme examination in Ireland had not been attended with success. It was the opinion of the Royal College of Surgeons that the union of the three medical corporations would be advisable, so as to reduce the number of licensing bodies in Ireland. He hoped that the matter would be referred back to the Colleges. He should prefer to have a union with the two other bodies, but if that were not carried out application would be made to the Medical Council or the Privy Council to appoint assistant examiners.

Dr. STRUTHERS supported the amendment. The matter ought not to be decided till the new members had been elected. There was a larger question depending on the result of the present motion. He thought that the English Conjoint Scheme ought to have included the Society of Apothecaries. The Council was now placed in a very serious position, and ought to pause before doing anything which would lead to the country being flooded with an inferior order of practitioners.

The amendment was then put, and carried by a majority of sixteen against two. It was also adopted as an original motion.

Mr. MARSHALL said that that concluded the business of the Council.

Dr. STRUTHERS said it was important to members living at a distance to know when they were likely to meet again.

The PRESIDENT said he desired to say a few words before the Council separated. In the first place, he wished to thank the Council for the great forbearance and kindness they had shown to himself and to the other officers of the Council in the conduct of the business of the session. He did not wish to magnify the small difficulties attendant upon an entirely new condition of things. But if members supposed that there had been no such difficulties they were under a misapprehension. When the Act of 1886 was passed, there were many things to be considered. First, he had to consider whether it was his duty to summon the Council for the purpose of deciding whether or not they would appoint a particular returning officer, or whether the President should take the initial responsibility, the Act stating that unless the Council decided otherwise the President was to be the returning officer. At the time he had to undertake the duty his valued friend, the chairman of the Business Committee, was not in England, and the solicitor for the Council was not immediately at hand. Various questions of great nicety arose. Letters of a most varied description, some serious and some very sprightly, were sent to the Registrar and himself with regard to numerous details concerning the mode of conducting the election. They had led to repeated consultations between the solicitor and his partner and himself (the President), and also to correspondence and interviews with the Government. By the kindness of the Secretary of State for War, it turned out to be possible to send voting papers to the large and valued body of professional men in the army, navy, and Indian services. That was not a matter for the General Council, but one which had to be undertaken by the Council's representative, and all he could say was that their representative faithfully did his best. He had refused to fix anything with regard to dates and arrangements, or any other subject connected with the election, except on the advice of the solicitor. He desired next to thank the Branch Councils for their kindness in accepting the arrangements that had been made, and carrying them out with the utmost courtesy and without cavil or question. One difficulty had arisen with regard to the meeting of the Council itself. He held the opinion, which he had expressed on former occasions, that the Council was bound to carry on its work just as if no Act had passed until the day when the additional members were added to it; and he should have been a traitor to their cause if he had not persistently endeavoured to continue the proper work of the Council until that date arrived. If the service of the profession and the country required it, he should not hesitate to summon the Council again before the 1st of January, but no such case was likely to arise. An objection had been taken to the meeting being held at that particular period. Various questions, however, might have arisen, legal technicalities, and so on, during the election, and it would have been most improper on his part to endeavour to carry on business, enabling the Council without interruption in case any such legal

difficulties arose in completing the election. Voting papers had to be counted, and if there happened to be a very close election a scrutiny of votes might be required. It was necessary that an adequate time should be allowed for the counting of the votes before the declaration of the poll, and he believed the shortest time that could be safely allowed had been provided. All the votes would be counted by the end of the next week, and on Nov. 29th it would be his duty to receive the decisions of the Branch Councils and to declare the results. He next desired to express his grateful thanks to Mr. Marshall, the chairman of business, upon whose judgment he implicitly relied, and who was at all times accessible; to the Registrar, who had been indefatigable under circumstances of great difficulty; to the printers, Messrs. Spottiswoode; to all the officers who had been engaged in the work, especially in the later days; and to Mr. Farrer, the solicitor, for the thoughtful assistance he had rendered. With regard to the next meeting of the Council, he could not decide the exact date, but he would do so at as early a period as possible. Before concluding, he wished to say that they were at present ignorant, and intentionally so, as to the gentlemen whom they would meet when they next sat round the Council table. If the present meeting had been delayed a little longer, they would have sat for the transaction of business after the election to the Council of gentlemen who could not sit at it; and one of the reasons which made it necessary for him to fix the particular date he had done was that they might carry on their deliberations without knowing who their future colleagues were to be. They were therefore careful that the business of the session should be concluded before they knew whom they would meet when the enlarged Council sat.

The session then terminated.

IRISH HOSPITALS AND MEDICAL SCHOOLS.

SESSION 1886-87.

Royal College of Surgeons: Medical School.—Professor FRASER said he would claim their attention for the time at their disposal while he endeavoured to unfold to them the lines along which scientific anatomy had developed to its present importance, forming as it did with its sister sciences of physiology and pathology, the basis of scientific medicine. It had followed particular nationalities—the Greek, the Roman, the Arabic; each of these had what was called a canon of medicine taught and disputed upon in the schools down to about a century or so ago. From the Italian its study radiated into France, England, and the Netherlands; passing through the latter, the Italian influence had been inherited and intensified by the German universities of to-day. Galen, the most celebrated of the Roman physicians, studied at Alexandria; and the Arab physicians, of whom the most noted were Rhazes and Avicenna, obtained their anatomy from him. Frederick II. founded the famous Universities of Bologna, Padua, and Pisa. It was in these that modern anatomy was instituted by Andreas Vesalius, born 372 years ago. Pupils of his, direct or indirect, were the teachers of the famous Harvey, the discoverer of the circulation of the blood. Anatomy had been advanced in England also by the two Hunters, by Huxley, Darwin, and the late Francis Balfour. In France the best known among its cultivators were Bichat, Lamarck, St. Hilaire, and Cuvier. In the Netherlands the names of Ruysch, Albinus, and Boerhaave were the most widely celebrated. From their German pupils, Haller, Lieberkühn, and Liebold, the present distinguished teachers of anatomy in Germany dated their origin.

Richmond Hospital.—Dr. NUGENT, in the course of his address, the subject of which was "Fever and Fever Hospitals," said fever was *par excellence* the disease of Ireland. After giving a sketch of successive outbreaks since the year 1731, Dr. Nugent went on to recount the great good done by the Hardwicke Hospital. Striking an average for the last forty years, it had annually admitted 1367 patients, and recently, when no special epidemic was supposed to exist, there had been seventy in it at once. In such a hospital students had facilities for studying fever unparalleled by any other clinical hospital in Ireland. That some students were nervous in the presence of fever he was aware, but he believed them to be an exception to the small minority. The lecturer quoted figures to show the comparatively small number of Irish medical officers who had died of fever.

Meath Hospital.—The address at this hospital was delivered by Mr. Ormsby, and published at length in our issue for the 6th inst.

St. Vincent's Hospital.—Mr. MCARDLE, having detailed some cases of joint disease in which he had obtained very marked results by the use of electricity, entered on the discussion of the influence of electricity on the micro-organisms which cause suppuration and other troubles. He noted the results of experiments which he had conducted in reference to this subject, and exhibited an instrument for introducing medicines through the skin without puncture by means of an electric current passed through it. He next referred to the question of admitting women to the medical profession, and held the belief that, as their engaging in such studies did not infringe any of Nature's laws, a carefully conducted course of medical training would in no wise influence the female character unless for good.

Adelaide Hospital.—Mr. HEUSTON, having given the history of the germ theory of disease, said that the pathogenic bacteria are specific beings, originating from and bringing forth their own peculiar species, gifted with unchangeable attributes, has been now proved by Gaffky; that they do not exist in healthy tissues, as stated by Koch, was proved by Hauser; while Tyndall has shown that no micro-organisms exist in the highest strata of the atmosphere, having exposed culture grounds for as long as twelve months on the higher Alps without their being contaminated. George Klemperer, an undergraduate in the Berlin University, made an important advance in this theory by proving that no suppuration occurs without the presence of micro-organisms. This has been quite recently further elucidated by Dr. Krautzfeld of St. Petersburg, who shows that it was always possible to detect micro-organisms in the pus of acute suppurations both by means of cultivations and direct observation, and the culture of those in the tissues he considers to be the most important factor in the etiology of acute suppuration. In a large number of cases of local acute suppurations the micro-organisms obtain admittance by means of an external wound. Abscesses due to the staphylococcus pyogenes are generally situated near the locality in which the micro-organisms enter, such as is the case in most of the ordinary acute abscesses, while those due to the streptococcus pyogenes are found at a distance from the place of injury, along the course of the lymphatic vessels, as is ascertained to be the case in pyæmia. The bacillus anthracis, described by Pollender in 1855, is the largest of the bacilli met with in disease, and is also the most virulent and difficult to destroy, it withstanding most antiseptics for a long period. These micro-organisms are to be found in large numbers in the blood of animals dead of malignant anthrax, which affection in the human being is popularly known as woolsorters' disease, the usual method of infection being by inhalation of spores. The bacillus tuberculosus was discovered by Koch in 1882 in connexion with phthisis, but since that period it has been proved to exist in a large number of tissues, and has been shown by Demme to be present in lupus. This bacillus may be demonstrated in the sputum, blood, and urine of those affected. The micrococcus erysipelatosus was found by Fehleisen in 1883 to exist in the lymphatics of the superficial layer of the corium and areolar and fatty tissue beneath, but was not to be detected in the capillaries or bloodvessels; this micrococcus is in character a streptococcus, but is distinct from the streptococcus of ordinary suppuration. Fehleisen has inoculated six cases of inoperable tumours with cultivations passed through many generations, and typical attacks of erysipelas resulted in three of the cases; one of lupus, one of cancer, and one of sarcoma. The result was beneficial to the patient. Pyæmia and septicæmia have for a long period given rise to a number of different theories as to the nature of their micro-organisms, some stating that they were bacilli and others micrococci, a number of both being present; but the weight of evidence now points to the supposition that both those affections are due to the streptococcus pyogenes, single, and diplococci, with the occasional presence of staphylococci. The study of these minute organisms opens a new page in scientific surgery, the importance of which we are only commencing to appreciate, and it is probable that succeeding generations of our profession will find ample occupation in their investigation, and the practical application of the knowledge thus obtained to the alleviation and treatment of diseased conditions.

Mr. Heuston's lecture was highly interesting, being illustrated by photographic transparencies and diagrams shown by the Cornu lantern.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 27, 1886.

AFTER having been allowed to slumber through the long vacation, the movement for a degree is again making progress among the London teachers, and the profession in general is beginning to show an interest in the question. The University of London declared through its Registrar in 1881 that its object, so far as degrees in medicine are concerned, is "to establish and maintain the highest attainable standard of professional acquirements. To increase the number of those who might seek the degrees of the University has been, in the estimation of the Senate, quite subordinate to the maintenance of the high qualification of its graduates." At the inaugural dinner of the London University Club in Manchester on the 13th inst., Sir JAMES PAGET, as Vice-Chancellor of the University, most definitely restated the same principle as the present standpoint of the University. "It was bound, not only for its own sake, but in fairness to the Government and the people, to maintain always that its degrees in the future, as in the past, shall constitute *distinct honours*, and that no one who had a degree from its hands should be able to point to it and say that it was not an evidence that he had passed *no ordinary examination*." The average student is still to be ignored, and only the exceptional one is to be considered. The practical outcome of these views was shown in our last issue. Thirty-six candidates only obtained the degree of M.B. Lond. at the recent Pass Examination, and but seven London schools are represented in the list. In 1881–82, the year in which most of these candidates would have commenced their medical education, more than 800 students began their medical studies in the English schools. Less than 5 per cent. of these therefore have obtained the degree of M.B. at the University of London. Can it be seriously argued that this is a due proportion of graduates, considering the ability and industry of the students, the teaching capacity of the professors and lecturers, and the wealth of clinical material and scientific apparatus at their command? No statistics or arguments could more conclusively prove the justice of the present demand for degrees for students in London on equitable terms with those in the other medical teaching centres. This demand is shown to be the more reasonable, and its justice becomes clearer, when we find that in the Scotch Universities 80 per cent. of the students entering in 1871-75 obtained degrees in the years 1876-80. We should also take into consideration that considerably more than 60 per cent. of those who have recently obtained medical degrees from the University of Durham have been educated (except for a year) in the London schools, and that many go from London to Brussels for degrees. The Victoria University has not been in existence sufficiently long for many of its pupils to have passed to the M.B. degree, but it is obviously so planned as to be attainable by every industrious student of average intelligence, and is not intended to be an honours degree.

The only objections that we have heard ho[illegible] against the institution of a new degree for London students are:—1. That any such degree would be confounded with the existing London degree. This difficulty might be easily obviated by the adoption of a distinctive name, such as M.B. Albert University or Westminster, or some similar title. Nobody mistakes the degrees of Trinity College, Dublin, for those of the Royal University of Ireland, though both are conferred in the same city. 2. That the curriculum of the London student is an inferior one to that required by the Universities. In medical studies, properly so called, the requirements of the Conjoint Examining Board in England and the severity of its examinations are quite equal, and in some respects even superior, to those demanded by some of the Universities; and we question if any candidates pass this Board in anatomy, physiology, materia medica, surgery, medicine, and midwifery who would be rejected in those subjects by the examining boards of the Scotch Universities. In the subjects of general education the present minimum should be increased, and a synopsis of the demands and limits in natural history should be added to the scientific part of the curriculum, and then no exception could reasonably be taken to either the thoroughness of the education or the completeness of the examination tests. These points are sure to be attended to by the authorities if a degree be granted. 3. That a degree can only be properly given by a University. In this, which will be found the most powerful objection to the proposed scheme, there is more sentiment than reason. Words are made to do duty for facts. If a stringent B.A. course and examination of the old style were still a necessary preliminary to a medical degree, as was until lately the case at Oxford, we could appreciate the argument. But now even at Oxford and Cambridge candidates can substitute for classical and mathematical training scientific subjects which have a direct bearing on their medical curriculum. In the Scotch Universities the medical department is simply a large medical school, and, except for the necessity of having passed a preliminary examination, a student has no necessary connexion whatever, except when he is capped, with the other Faculties. The University of Durham, except on paper, is quite unknown to the medical student at Newcastle-on-Tyne. Similarly at Liverpool and Manchester he may be ignorant of the name of the principal, or even of a professor in the Faculty of Arts of the Victoria University, and their existence is only made known to him at his matriculation examination, and at the ceremony at which his degree is conferred. The advantage, therefore, of the culture derived from contact with the other Faculties by a residence and training at most of the Universities in the case of a student in medicine, when contrasted with his London competitor, is quite fictitious. Culture and habits depend in both cases on the student himself, his previous education, and his choice of associates, and can be no more claimed as exclusively belonging to the Universities of Edinburgh, Glasgow, and Aberdeen, than to University or King's Colleges, or to St. Bartholomew's or Guy's Hospitals. Not only are the medical and other Faculties quite distinct in our modern Universities, but even in the starting of a new University, unless it is to spring forth fully equipped, a Faculty must be first formed, and [illegible] Faculties must be afterwards

congregated. We hope to see a teaching University in London, as in our other large cities, but the only hope for this seems to us to lie in the vigorous prosecution of the present movement by the London Colleges. If, through inertia or a want of a clear understanding as to their needs and position, the teachers of arts and science in London fail to combine into other Faculties, as at present appears only too likely, a distinct advance will at any rate have been made if this proposal for the establishment of a London medical degree should be successful. An admitted want will thus be supplied and an evident injustice remedied, and no further justification can be required for the scheme and its energetic prosecution.

MR. JUSTICE DENMAN recently gave judgment in a case where the plaintiff was a person who had been confined in a lunatic asylum under a certificate drawn up and signed by the defendant. Malice, of the sort which consists in neglect, was alleged in support of the plaintiff's plea; but on investigation the allegation was reduced to one of inaccuracy of a very slight character in the particulars set forth in the form; and even this plea was unsustained except by the evidence of the plaintiff, who spoke from recollection of what she had done and said eight years previously. The plaintiff was practically nonsuited on the ground that the action was not commenced within twelve months after the commission of the act alleged—that is, the giving of the certificate,—or even within twelve months of the discoverture of the plaintiff by the passing of the Married Women's Property Act; but in some technical way the case was brought under the cognisance of the jury. The jury failed to arrive at a verdict, the Court was moved to give judgment for the defendant, and Mr. Justice DENMAN complied without calling upon the defendant's counsel to argue in support of the plea. It is therefore a specially valuable judgment that was obtained. On the question of malice in respect to the giving of a certificate, Mr. Justice DENMAN adopted the view taken in the recent case of CLARK *v.* MOLYNEUX—namely, that "that which may be a mere want of recollection or inaccuracy ought not to be considered evidence of malice, but only that which exhibits a bad mind and wrong motive in the matter." This is so obvious as to carry the force of truth in its expression. There is, however, one point in the judgment to which we must, with great respect, beg to take exception. "It is not," proceeded Mr. Justice DENMAN, "at all a sound view that if a man is deceived or takes a wrong view in giving a certificate of lunacy, the person who is certified is confined to his or her harm or evil. They are confined for their good, and in this case it would have been for the plaintiff's good to be confined." In so far as this is another way of saying that the end justifies the means, we must take leave to differ from Mr. Justice DENMAN. It may be not harmful, but advantageous, on certain grounds, to a man or woman to be confined in a lunatic asylum. For example, he or she may benefit by rest and relief from work or worry; mind or body, or both, may be advantaged, and yet the means by which this advantage has been gained may be unjustifiable either by fact or inference. It is no justification of a false conviction that the prisoner has [illegible] and moderate diet of life in prison. [illegible] really intended to express this view, we are quite sure that on reflection he will perceive that it is erroneous and untenable. Meanwhile we hail the frank and clear utterance of the judge, limiting the forensic, if not the legal, idea of malice to genuine *mala fides*, as most opportune and useful.

Judgments like this are greatly needed; and if practitioners are not to be driven by fear of vexatious actions at law to refuse the giving of certificates, something must be done to clear away the clouds of doubt and jeopardy which render it perilous to take any step in a case of lunacy, and do not only prompt, but compel, all but the specially bold or reckless among us to stand still. How very undesirable this position of affairs really is will appear when we reflect that *not* to place an insane person promptly under treatment is scarcely, if at all, less opposed to the best interests of the individual and of society than to consign a sane but eccentric person needlessly to confinement. We have counselled and must continue to advise practitioners to decline to give certificates in all but the most obvious cases of madness—in those, in fact, in which certifying is a mere formality—until the question of responsibility is finally settled in such a manner as to secure every medical man who acts honestly and to the best of his ability from the persecution of the convalescent. As the matter now stands, it is coming to be regarded as a point of honour on the part of a certain class of patients to endeavour to rehabilitate what they conceive to be a ruthlessly or recklessly damaged reputation for sanity by taking proceedings against the medical men who signed the certificates on the strength of which they were confined. Anything more mischievous than this position of matters it would be difficult to imagine. It is nothing to the point to say that those who bring actions vexatiously generally lose their suits. The medical man persecuted is injured in mind, body, and estate by the treatment to which he is subjected, and it is a scandal to the cause and interests of public justice that actions of this class are allowed to be brought without the *fiat* of some official whose duty it should be to see that at least a *primâ-facie* presumption of malpraxis or neglect actually exists. No pecuniary award can possibly compensate for the pain and strain inflicted on the practitioner assailed. Something effective must be done to protect the medical profession against this sort of thing, if the very clumsy and dangerous system of "certifying" which at present so strangely satisfies the public and political sagacity is to be maintained in all its elaborate fertility. Until a really radical change is made, we trust practitioners will at any cost or trouble, simply decline to place themselves in peril, and refuse to give certificates at all, leaving the lawyers to find a way out of the difficulty created as best they may.

In another case of wholly groundless action against a medical man who had signed a certificate, Mr. Justice MANISTY has expressed himself in forcible terms against the wrongfulness of the law which permits the bringing of these actions without even adequate security for costs. It was a terrible thing for a gentleman in the position of the signer of the certificate "to be called on to defend himself from a charge of this sort on the chance of a party being [illegible] to get something out of him, and with the certainty [illegible] The Co[illegible] enabled [illegible] successful he could only get his taxed costs, and

would be still out of pocket." Everyone will agree with Mr. Justice MANISTY, though whether the way sketched out by the judge for getting out of the difficulty is the best that could be devised is a debatable question. "He thought it would be well if the Court had a discriminating power to order security for costs to be given in such cases." We venture to think it would be better if, as suggested above, the *fiat* of some public official representing the Secretary of State were made the preliminary condition of proceedings against the medical man, or men, signing the certificate. The question involved is not one of money solely, but of character and professional credit, which are of more than financial importance to the majority of practitioners. There cannot be any doubt on the mind of any observer of the working of our very defective Lunacy Laws, that they need immediate and thorough reconstruction in the interest of all classes of the community, whether sane or insane, to which their influence extends.

IN an article published last week we drew attention to the precipitate act by which the Councils of the Royal Colleges of Physicians and Surgeons have broken off negotiations with the Apothecaries' Society on the subject of a conjoint examination. We mentioned some of the untoward consequences which are likely to follow this high-handed proceeding. Emanating as it does merely from the influential oligarchies of the Colleges, it can represent only in part, if at all, the opinion of the large body of practitioners whose views have been thus summarily anticipated. The Members of the College of Surgeons had recently an opportunity afforded them of publicly expressing their wishes on the subject. They did so in a most reasonable and temperate manner. A resolution was passed in the presence of the President and Council without any evidence of dissent, any expression of opinion, or any information being vouchsafed. Meantime, however, resolutions were adopted and confirmed in the Councils of both Colleges of an entirely contrary effect. It is not surprising, then, that the general practitioners have determined to act for themselves. They can only do so effectually by combining; and it cannot be doubted that an "Association of General Practitioners" such as that which is in process of formation will afford the best and most effectual means of giving organised expression in the future to their wishes.

A full consideration of the whole question must therefore constitute the work of the next general meeting of the Fellows and Members of the College of Surgeons. It is, in the circumstances, only fair to them that a special general meeting should take place at an early date; and it is to be hoped, alike in the interest of the public and of the profession, that the too hasty decision of the Colleges will not prove irrevocable. Meanwhile, the temporary lull in operations affords a fit opportunity for reviewing the relative positions of the parties in this question. The services which have been rendered to medical education in the past by the Society of Apothecaries are undoubtedly considerable. At a time when the Colleges of Physicians and Surgeons were each absorbed in the fascination of its own department of practice and careless of the educational needs of the [illegible] tioner, the Society, alone of London corporations, afforded its *alumni* what was for that day a wide and clear, though imperfect, perception of the field of professional duty. Since then changes have come about. The pattern, modelled with some fidelity on the system pre-existing at the universities, has been recast in a more substantial form in the licensing course exacted by the Colleges; while new and powerful forces have been directed to the same purpose by the University of London and various schools of recent growth. It is therefore, perhaps, not to be wondered at that medical opinion, not confined by any means to leading members of the profession, had come to regard the licensing function of the Society as a power which had done its work, had become unnecessary, and, not without respect, had practically passed away.

It appears certain that one result of the exclusion of the Society will be to excite in it the instinct of self-preservation. At present it is willing to play a part, and a modest part, in the scheme of medical education. Debarred from uniting with the Colleges, it may be relied upon to seek at the hands of the Medical Council—or, in default of that body, of the Privy Council—the addition of such examining powers in surgery as would legally justify its existence as a separate licensing authority. These powers it would in all likelihood obtain without question. Then we should find that another body of legally competent practitioners, attracted by the cheapness and facility of the revived curriculum, would be annually ushered into the already well-contested field of general practice. Nor can we pretend that such a competition would be ineffective. Had we everywhere a discriminating public, able to estimate the relative value of qualifications in medicine, and, on the other hand, a general agreement as to charges on the part of practitioners which would adjust itself to the varying necessities of our population, then perhaps the influence of a less ambitious qualification might be disregarded. Such a Utopian condition unfortunately does not exist, nor is it likely to appear for some time to come. In the meanwhile the probable effects of a reconstitution of the Society's powers in such a form as we have indicated should not be underestimated. The readiest, and indeed the only visible, way of escape from the dilemma is that the Colleges should reconsider the offer of the Society to join its examining function to theirs before it is too late. If we look at the question from the point of view of the Colleges themselves, we fail to see that their professional dignity or their fitness to qualify under the present arrangement is necessarily impugned by the measure we are advocating. Granted that together they are quite efficient for the work, it is still apparent that several subjects included in medical education fall within the sphere of the Apothecaries as much or even more than within their own. Such are Chemistry, Pharmacy, Materia Medica, and part of Medical Jurisprudence. This ought to show that a further division of the labour of education is possible, as well as in the present case advisable. The importance of a thorough and early training in Materia Medica and Pharmacy is not to be ignored. These studies do not now, as in olden times, it is [illegible] tative front of Medicine. Scientific [illegible] ate consequence, and the great

extension of clinical knowledge itself, have placed them in the background. With a great many practitioners in this country, as on the Continent, the tendency is to leave Pharmacy behind in the stage of studentship, and the tendency seems rather to increase than to diminish. There is on that account, in our opinion, all the more reason why education in this branch should be thorough both in theory and in practice; and why not entrust it, with allied matters, to the Society of Apothecaries? We shall not now, however, pursue this part of the subject further. A good deal has been said of the power of prosecution for unqualified practice, which at present rests largely in the hands of the Society. We do not profess to be satisfied with this arrangement, and regard it as only reasonable that adequate powers should be vested in higher authorities for the protection of the profession in this respect. Still, facts as they stand must be considered, and it should not be forgotten that the Colleges, in refusing combination with a body which exercises its defensive privilege more successfully than the purely medical corporations, are depriving their Members and Licentiates of a useful barrier against unfair competition and imposture.

IT is just twenty years since Dr. P. H. WATSON of Edinburgh performed the operation of excision of the larynx for the first time. BILLROTH soon after repeated the operation with a fairly successful result. He was followed by the late Dr. FOULIS, whose successful case excited much attention in this country. Since this the operation has been frequently performed in Germany, and the total number of cases now nearly approaches a hundred. Four cases were related at the last meeting of the Clinical Society, which are the first that have been recorded by London surgeons. In two of them—Mr. MORRIS'S and Mr. PICK'S—the operation was performed for advanced malignant disease of the larynx, and in the former of the two a palliative tracheotomy has been found no longer effectual in relieving the dyspnœa. In two other cases—Dr. SEMON'S and Mr. BUTLIN'S—the operation was undertaken for earlier malignant disease, as a means of its total removal, with the hope of securing long if not permanent immunity from the disease. These cases both ended in rapid recovery, and at the present time the condition of the patients is satisfactory. The record of these cases will no doubt again direct the attention of British surgeons to an operation that has not hitherto been regarded with much favour by them; and while it is to be hoped that it will not lead to a frequent repetition of the operation, it may well conduce to the formation of a truer estimate of the worth of this procedure.

Like every other novel form of treatment, this operation must pass through an experimental stage before surgeons can determine exactly its perils and its worth. By experience it will be made evident what cases are suitable to submit to it and what are not, and although *a priori* reasoning should guide surgeons to some extent, its value must be put to the test by experiment. The early statistical results of excision of the larynx are therefore not a true guide to its dangers. They will reveal failure from an improper selection of cases, and from the neglect of due precautions against certain dangers. [illegible] is so the early operations are [illegible] basis for an intelligent and wise opinion and their value is not to be under-rated.

Already we have learned some important facts about excision of the larynx. Apart from an improvement in certain technical details of the operation itself, it has been shown that one of the chief dangers lies in the liability to septic broncho-pneumonia. This can be largely, if not entirely, obviated by taking care not to allow any blood to find its way into the lungs, and also by the use of an antiseptic material to plug the wound. It has been shown, too, that excision of the entire larynx is a much more dangerous procedure than removal of a part—say of one-half. It also seems clear that only a small proportion of cases of laryngeal cancer are suitable for this operation; these are those in which the disease is strictly intra-laryngeal in origin, and has not extended at any part beyond the limits of the organ of voice. Mr. BUTLIN seems to think that in some, if not in many, of these cases it would be sufficient to split the anterior border of the thyroid cartilage—thyrotomy—and then to remove with knife and raspatory the soft parts within the larynx, while leaving the cartilages in their place. What we want further information on is the real mortality of the operation, what its dangers are, what immunity from recurrence it offers, how far it can be regarded as a curative procedure, and what degree of mutilation it inflicts. Dr. SEMON'S patient was very soon able to take food in the ordinary way, and within a few months of the operation could speak in a loud whisper, and desired to return to his duties as a barrister. Evidently the last word has not yet been spoken in reference to the necessity for wearing an artificial larynx. Mr. BUTLIN'S practice of excising the soft parts of the larynx and leaving the cartilaginous framework behind must be tested. We shall hopefully await experience on these points. The feasibility of the operation has been well demonstrated; the conditions that favour its immediate success are known, and those that determine its ultimate success seem to be clear. Advancing on the lines thus worked out, we may hope that before long our estimate of the real value of this operation will be corrected and established.

THE ill-timed meeting of the Medical Council came to an end last Saturday. Besides purging the Register, and making provision, under the Act of this year, for the registration of diplomas in Sanitary Science, it would be difficult to point to any work which can be regarded as worth the expenditure of time and money which it involved. There was such a dearth of serious business that much time was occupied in discussing points of form and in humble imitations of the House of Commons. Nevertheless, there were significant incidents in the proceedings which may advantageously occupy a few minutes of our time and that of our readers. The first of these was the Address of the President, and particularly that part of it referring to the Medical Act of 1886, under which an election of Direct Representatives has just taken place. This election and its effects are to be the subject of more specific attention hereafter, the President only venturing to presage that those about to be added to the Council will not be less earnest in its work than the [illegible] members. We cannot doubt that the President's [illegible] enabled [illegible] be justified by the Direct Representatives.

It is more instructive in our view to notice the significant words of the President in reference to the great defects of the Act of 1886. We have never thought of it otherwise than as a very faulty and defective piece of legislation, which could never have been proposed but for one of two reasons: either, first, that, as the President says, "the nature of parliamentary government makes any serious change in our educational procedure impossible,"—in which case we say so much the worse for parliamentary government, and for all who are ruled by it; or, secondly, that the Government was misled by those who should have known better, and were induced to believe that the mere grant of Direct Representation would so satisfy the profession as to make it indifferent to other and even older objects of medical reform. It is satisfactory to us to remember that we were never under any such delusions, but fully sensible of the fact that the Bill did not pretend to grant what all reformers have wished and all recent Bills attempted to secure—namely, a consolidation or conjunction of the licensing authorities. But let us see what the President says about this feature of the Bill: "Modifications in the examination system, once held to be of the first importance, and therefore of greater consequence than a change in the executive, are left untouched by the Act of 1886. The licensing bodies all retain their respective and separate powers." The gravity of such an admission by the President of the Council cannot be exaggerated; nor is it abated by remembering that the President never thought it worth while to call the Council together to consider this Bill, or to point out to Sir LYON PLAYFAIR and the Government that they were ignoring the principal recommendations of their own Royal Commission and the principal wishes of all statesmen and medical reformers who had given any attention to the subject. But it may be said this is a mere theoretical piece of criticism, and has no practical bearing. No one will venture to say so who allows himself to consider what may happen under such a clause as Clause 5. The special object of this clause has been thought to be the preservation of the Apothecaries' Societies in England and Ireland—a preservation which cannot be condemned in the present state of medical politics. But it is easy to see that it may be wrested by every corporation of each division of the kingdom to its own uses, and lead to all sorts of fantastic bodies, or that under Clause 3 and its subsections a number of new combinations might arise, which, while satisfying the fundamental requirements of the Act—that of a triple qualification in medicine, surgery, and midwifery,—would imply a competition in degrees and diplomas exceeding that which led to the demand for legislation, and has at times amounted to a scandal.

We can only rejoice that the present imperfect Medical Council had the good sense to defer the consideration of a scheme for the combination of two Irish corporations, leaving out a third, till the next meeting of the Council. It is an open secret that one of the great Irish corporations was willing to include the Apothecaries, and that only a small majority of the other was unwilling. But, nevertheless, it is so far left out in the cold, with the power to come to the Medical Council and ask for the appointment of assistant examiners. It will then enter into competition at more reasonable charges with the two Royal Colleges, which in their turn may be induced to entertain similar arrangements or other alliances, with results that no one can exactly forecast.

The registration of Diplomas in Sanitary Science is a noteworthy event. It marks the importance attached by us in England to that branch of medicine which endeavours to prevent disease, as distinguished from that branch of the profession which contemplates its cure. It has ever been the credit of the medical profession to be before the public in attempts to remove the very causes of disease—to prevent its occurrence. This has been the peculiar glory of English medicine, led by SIMON, RADCLIFFE, FARR, and others; and it is but fit that English legislation should have made provision for the registration of diplomas or degrees in this branch of science. An attempt was made to register them under a uniform title, but this did not succeed, Dr. HUMPHRY and Sir WILLIAM GULL maintaining that only the bodies which granted the diplomas could regulate the titles attaching to them. This is sound reasoning, but the bodies themselves should consider the question of title and try to agree on certain principles.

St. Bartholomew's School, always distinguished, was questionably so during the recent meeting by its unfavourable reply to an overture from the Medical Council proposing to visit it and all the other schools of the country. This led to a slight passage of arms between Sir WILLIAM GULL and Sir DYCE DUCKWORTH, which, however, as might be expected with such generous and courteous belligerents, soon ended amicably. The competence of the Council to make these visits is still undecided. But it would be a pity for the sake of students if they are not made, and a greater pity still if a leading school like Bartholomew's were to set the example of resistance to the Medical Council. When such heavy batteries are manufactured against the student's chances, it would seem but fair to him to ascertain the efficiency of his schools and their appliances.

SOME hope has been expressed that Mr. RITCHIE, the President of the Local Government Board, will shortly be raised to the rank of a Cabinet Minister. The reasons that have led to the existence of this expectation are not stated in the journals which discuss the subject; but we may assume that Mr. RITCHIE's undoubted ability has indicated the desirability of including him among the chief State councillors. However this may be, it is probable another thought has also had weight in suggesting this important change. Mr. RITCHIE, as President of the Local Government Board, holds an office which is second to none in its influence on the prosperity and happiness of the country. The large subject of Poor-law relief is immediately under his control; the education of an important section of the community, and all questions of local government generally, come within the scope of the Board over which he presides. No doubt Cabinet rank would not be considered necessary for the chief of a department dealing with many of these subjects, but among the questions of local government with which Mr. RITCHIE is associated is that of public health. For this it may safely be said merely the concern of a number [illegible] health is, indeed, an imperial

question. Upon its preservation is dependent the prosperity of the nation. The relations of this country to others, especially in regard to trade interests, are intimately bound up with questions concerning the prevention of epidemic disease; there are therefore reasons of the highest importance why public health considerations should have due weight with Her Majesty's Government, and the Minister who represents this vast interest should have all the opportunity for influencing the decisions of the Government that is accorded to other high officers of State. But we have before expressed a strong opinion that public health, even under these circumstances, is insufficiently represented. So long as it is allied and in many ways subordinated to Poor-law administration full justice cannot be done to the health interests of the nation. It is now twelve years since we urged the necessity for the creation of a separate Ministry of Health, and from that time until the present the idea has gradually grown until it has come to be accepted by an increasing number of people.

Eight years ago Dr. B. W. RICHARDSON read a paper at Stafford on the Constitution and Functions of a Minister of Health for the United Kingdom; his proposal was that the Registrar-General's office should be the nucleus of a ministry which should deal with all health questions throughout the British Isles, and he considered that it ought to be essentially educational and expository, but not administrative. We ventured to dissent from this view; it is difficult to say whether in the future local authorities may be trusted with complete independence of action in all matters relating to public health. Certainly the central authority would always have as its chief function the duty of obtaining information which could be utilised by local boards, but for many years to come some supervision over their action will be necessary. If we might foreshadow the development of an internal administration, it would include not only the enlargement of many powers of local authorities, but the creation of a service of the State that would bring local officers into more intimate relation with those whose duty it would be to advise a responsible minister. Such a service would ensure the employment of a higher ability than that which is now brought to bear upon local work, and would promote the independence which is necessary for the proper fulfilment of duty. Under such a system the still young subject of public health would develop at a much greater rate than it can do under existing circumstances. Public opinion is ripening for such a change, and successive statesmen have recognised the growing importance of the health-welfare of the people. Lord BEACONSFIELD created hopes which are still waiting to be realised, and Mr. RITCHIE'S promotion to the Cabinet would show us that his late chief's paraphrase was not altogether forgotten. The position which the President of the Local Government Board occupied in a late Administration proved of material value to the country, and we would fain hope that the able statesman, who would thus be brought into closer contact with his colleagues, may have opportunity of helping further in the attainment of the end we desire.

An examination for twenty-eight [illegible] as surgeon in Her Majesty's Indian Medi[illegible] Feb. 14th, 1887, and f[illegible]

Annotations.

"Ne quid nimis."

THE VICE-CHANCELLOR OF THE UNIVERSITY OF LONDON AT MANCHESTER.

At the inaugural dinner on the 13th inst. of the London University Club, which has been recently formed at Manchester, Sir James Paget, in replying to the toast of "The London University," made some important statements with regard to the prospects of the reform movement in the University. Sir Henry Roscoe, M.P., the President of the Club, dwelt most felicitously on the past history of the University, and showed that it had always been to the front in educational matters—as in abolishing religious disabilities, in establishing the highest class medical degrees, in granting degrees in science, and in admitting women to degrees. As Manchester has seceded from London, that it might become a Teaching University, it was certainly very magnanimous on Sir Henry Roscoe's part to say that "self-taught men, who by their own endeavours had obtained a knowledge sufficient to pass the examinations, were deserving of University recognition." The authorities of the Victoria University, however, take care that this recognition should be given, not by themselves, but by some other University. Sir James Paget, as Vice-Chancellor, referred to the various schemes now suggested for increasing the value of the University in the future, although he offered but little encouragement to their promoters. Its degrees are to be obtained on no easier terms, and it will never narrow its field of work. The London University is therefore to remain an Examining Board for the English-speaking world, and its portals are to be open to all. Examinations themselves, even if they did engender cramming (and are not Cabinet Ministers crammed?), are most potent instruments for teaching. "In that way they could determine what should be taught, how it should be taught, and what measure of learning a candidate must arrive at." Undoubtedly; but this very power in the hands of an irresponsible Senate, elected for life, with scarcely an actual teacher now among its number, has rendered possible all the mischief attributed by teachers to the University, and was the one reason (non-local) advanced by the professors of Owens College in support of their application for a new Charter. As regards the change into a Teaching University, Sir J. Paget thought "the greatest probability was that the teachers in London and the principal teaching institutions of the country would be invited to arrange plans by which they might have a more considerable influence in the University itself, by which they might be represented on the Senate, become members of the body of teachers who would guide and advise what should be the course of teaching in the University." These intimations must be widened very considerably, before they will do away with the agitation for internal reforms which are thought necessary, or satisfy the aspirations of the London teachers or the graduates of the University.

THE PROPOSED CONVALESCENT SMALL-POX HOSPITAL.

THERE is a serious difference of opinion between the Local Government Board and the managers of the Metropolitan Asylums District as to the desirability of building a permanent hospital for convalescent cases of small-pox at Darenth. It will be recollected that in 1884 both Boards agreed that further provision should be made for cases of small-pox, and that a permanent hospital should be built for [illegible] at Darenth. Subsequently, however, before the [illegible] commenced, the managers were compelled to

erect on the site a number of tents and huts to meet the exigencies of an epidemic; the building of the permanent hospital was therefore postponed, but the managers are now desirous of giving effect to the decision at which both Boards have arrived. The Local Government Board has since changed its mind, and now declines to sanction any other erection than one of a temporary character. The reply of the managers is that the difference between the amounts of money expended for the two purposes is apparent rather than real, and that the cost of repair and of heating, and the increased expense of administration of the temporary hospital, would soon lead to as great an expenditure of money as if a permanent building were erected. We do not doubt that the Local Government Board sees the necessity of future small-pox hospitals being constructed very differently from those which have given rise to small-pox in their neighbourhood, but this ought to be definitely stated, and the managers should be given the opportunity of determining without loss of time how small-pox hospitals must in future be built. The Central Board has by its reference to the uncertain state of medical knowledge indicated the need for further knowledge; and if this need really exist, it is certainly the duty of one or other body to see that its acquisition is undertaken with as little delay as possible. If the opportunities afforded by past epidemics had been fully utilised, there would have been no need for the experience derivable from other outbreaks of disease. As it is, London has the satisfaction of throwing away some £60,000 or £80,000 because a few hundreds have not been expended in obtaining the medical knowledge which is now held to be necessary before a permanent hospital can be provided.

FURTHER RESEARCHES ON CHOLERA.

THE epidemic of cholera which has been prevalent in the north of Italy during this year has offered the occasion for a study of the disease, which has been made by Drs. Tizzoni and Cattani of Bologna, the results of whose researches are contained in a recent number of the *Centralblatt für Med. Wissensch.* It is interesting to find that Koch's researches are confirmed and extended. The authors' chief conclusions are contained in the following propositions: (1) The bacilli which were present corresponded in biological and morphological character with those described by Koch, Ermengen, and others as the comma bacillus, and they were constantly present in the twenty-four cases examined. (2) They were found in the alimentary canal and the dejecta, and were capable of cultivation, so that when present in small numbers this method permitted their presence to be ascertained with greater certainty. (3) Of these twenty-four cases in which the bacilli were found, one was a case of the prodromal diarrhœa, and three were cases of cholera typhoid, which succumbed respectively on the sixth, seventh, and fifteenth days. (4) That the comma bacillus is of the utmost importance for the differential diagnosis of Asiatic cholera. (5) Even after large doses of calomel, quinine, thymol, and ethereal extract of male fern, bacilli were found in the intestines and dejecta, capable of cultivation. The bacilli were found in the vomit and contents of the stomach in several cases, and were capable of cultivation. In a case where they were absent the vomit was sour. (6) The blood-serum taken during life from the arm and in the cadaver from the right heart was always alkaline. (7) The bacilli were present in the serum and in the white blood corpuscles in small quantities, but were incapable of cultivation. (8) The subarachnoid fluid, which is much increased in cholera, also contained them, but only once was a successful cultivation obtained, when the weather was warm and the necropsy was made about two hours after death. (9) The comma bacilli are capable of multiplication and [illegible] not only in the soft parts of fruits but also on the "skins." (10) Flies probably play an important part in the propagation of the disease, as they were found to be capable of conveying by their feet the microbe from a cultivation to a suitable medium, and flies removed from the wards and "cultivated" gave a crop of micro-organisms, among which the comma bacillus was predominant. The importance of the results here catagorically stated is obvious, as a confirmation of many points which had been previously ascertained; but we should like to call attention to one fact which has a practical bearing—viz., the incapability of the bacillus to live in an acid medium, such as the gastric secretion, in times of health. Assuming this fact to be true, and that the chief mode of entry of the bacillus is by the digestive organs, it is obvious that it can only affect the body when the acidity of the stomach is very much lessened or reduced to *nil*, so that it behoves everyone in times of the epidemic to exert more than usual care to prevent any disturbance of the functions of the stomach or the lower alimentary tract, and to abstain from succulent fruits, which, besides the property they possess of deranging the alimentary canal, can also act as direct means for the introduction of the bacillus.

LIVERPOOL HOSPITAL SUNDAY FUND.

WE are sorry to have to record a Hospital Sunday collection in Liverpool this year less than in 1885 by £179 8*s.* 10*d.* Exclusive of donations it was £319 12*s.* 1*d.* less. The result is explained not only by the depression of trade, but by the very unfavourable weather. The Hospital Sunday is placed, with doubtful advantage, in January. We are glad to say that it is under consideration to transfer it to May. Many churches and chapels still fail to make any collection for this purpose. Fortunately there is an increase in the Saturday collection. The sum raised in this way is chiefly given by artisans and working people. It is £3147 7*s.*, as against £2603 3*s.* 6*d.* last year. Credit is due for this to the officials and members of the Working Men's Committee. Though we do not think the contributions of the working classes at all in excess of their obligations, or even equal to them, it is serious to note that the church collections are very far short of them—the opposite of the London case, where Sunday so far exceeds Saturday. This is a holy cause, in which one class may well provoke another to good works. The claims of eighteen charities to a participation in the Fund were submitted and paid, with the exception of the Hospital for Women in Shaw-street. In this case the committee thought the award should be withheld pending investigation now in progress.

RECENT OUTBREAKS OF SMALL-POX IN LIVERPOOL.

DR. E. W. HOPE, assistant medical officer of health, and lecturer on Public Health at University College, Liverpool, has discussed in a pamphlet recently issued, the behaviour of small-pox in Liverpool during the last twenty-five years. In this period there were ten years in which the number of deaths from this disease exceeded fifty: in one year, 1871, the deaths amounted to as many as 1919; in each of the remaining fifteen years the deaths amounted to less than fifty. Dr. Hope estimates that 8 per cent. of the total population, or 46,905 persons, altogether escaped vaccination, and after allowing for such of them who have contracted small-pox, he concludes that fully 46,000 persons remain who are in no way protected against this disease. To these must be added those adults who have not been vaccinated since infancy, and still younger persons who have been badly vaccinated in infancy. He contends from this that Liverpool contains a large amount of susceptible material. The opportunities [illegible] small-pox are considerable; apart

from those cases which come by land, vessels arriving in the port not infrequently become centres of infection; thus Montreal, which last autumn was the seat of a severe epidemic of small-pox, contributed eleven cases. In discussing preventive measures, Dr. Hope argues against domestic isolation, and gives instances of the evil results which follow from the adoption of this plan. With regard to hospitals, he says that there was considerable spread of small-pox from two of them, which are each situated in populous districts; concerning the third hospital, which is several hundred yards from any dwelling, no cases of small-pox have occurred near it, although upwards of 600 patients have been treated in it. Dr. Hope does not enter into detail as to the exact distribution of the cases surrounding the hospitals. We would commend the subject to him as well worthy of the closest investigation. His own opinion is that a space of three or four hundred yards between the hospital and the nearest inhabited street is sufficient, but it is quite possible he might modify this opinion if the incidence of the disease were studied on the same lines as was that of small-pox round the Fulham Hospital by Mr. W. H. Power. The small-pox statistics which illustrate the paper teach the same lesson as those of other hospitals for this malady.

OUR MILITARY PRISONS.

THE report of the Inspector-General of Military Prisons for 1885 is characterised, like its predecessors, by the very small amount of information it affords respecting the health of the prisoners. In one of the tables appended to the report the number of hospital cases which occurred in each of the prisons is given; but no reference is made to the deaths, if there were any, or to cases sent from prison to the Station Hospital. In another table eleven men, five at home and six abroad, are returned as "disposed of" for causes unspecified, but whether any of them died is left to conjecture. Nor do we find any information deserving the name in the few brief extracts from the reports of the medical officers of the home prisons, except from Gosport, in which it is stated that "the use in the prison of water from the Gosport Water-works Company for cooking and drinking purposes, in place of that from the well in the yard, has been followed by the most satisfactory results as regards the prevalence of bowel complaints among the prisoners. Diarrhœa, which formerly was frequent, is now of rare occurrence." The proportion of hospital cases in the various prisons at home ranged between 80 per 1000 in Limerick and 477 in Cork; in the English prisons, the highest ratio was 274 per 1000 in Brixton, and the lowest 90 in Chester. These differences, though by no means so great as those shown in previous reports, are still sufficiently marked to deserve an inquiry into the causes upon which they depend. In the military prisons abroad they are even more striking than at home, for the cases range between 133 per 1000 in Bermuda and 1772 in Halifax, N.S. A return of the diseases which came under treatment would be interesting, and might possibly furnish a clue to the causes of this marked difference. At Alexandria the cases amounted to 455 per 1000, but this high ratio was the result of local insanitary conditions. The medical officer states that "owing to the excessive number of fever cases which occurred during the early part of 1885, the building underwent a complete sanitary organisation; the old and foul latrines, with their choked-up pipes and ancient cesspits, were completely removed from the interior, and the dry-earth system substituted in the adjoining yard. Also the water arrangements, which were found to communicate with the above pipes, were set right. The cells and corridors were better ventilated and better lighted. ..... Average number of sick less than half what it was before the above recommendations were carried out." The number of committals to military prisons [illegible] at home amounted in 1885 to 7018, being in the ratio of 7·8 per cent. of the strength. In proportion to the numbers serving of each nationality, the Irish furnished 12·9, the Scotch 10·4, the English 6·4, and foreigners 4·7 per cent. It is to be regretted that little progress has been made in providing suitable industrial employment for the soldiers in military prisons. In conclusion, we must express our disappointment that the information given in the Inspector-General's report regarding the health of the military prisoners should still continue to be so meagre and unsatisfactory.

RUPTURE OF THE BLADDER.

IN THE LANCET of Oct. 2nd, p. 634, we mentioned the case of a labouring man who had been successfully treated for intra-peritoneal rupture of the bladder by abdominal section and suturing of the wound. Another patient has also been operated on by the same surgeon, Sir William Mac Cormac, in St. Thomas's Hospital, and with an equally satisfactory result. Although we hope to publish shortly a full account of these two cases, still it will be interesting to our readers to learn some of the main facts about this second patient. He was a stout, healthy man aged thirty-six weighing about fifteen stones, and the injury was caused by a fall of nineteen feet from a scaffold on some soft clay; he alighted in a sitting position. The man had passed urine about an hour before the fall, but none was afterwards voided until relief was obtained by catheter on admission to the hospital a day later. The symptoms were, briefly, abdominal pain and tenderness, chiefly in the hypogastric region, general slight distension of the abdomen with evidence of fluid in the peritoneal cavity, a slight amount of urine of a muddy, smoky appearance found in the bladder when the catheter was passed, and a history of ineffectual attempts at micturition. There was a bruise over the left ilium, the patient looked anxious, had a quick pulse, and complained of nausea. At the operation, which was performed about twenty-seven hours after the accident, a rent of an inch and a half in length was found near the upper part of the posterior surface of the bladder, the peritoneal wound being larger than that of the mucous membrane. Twelve interrupted silk sutures were used. All the urine was washed out of the peritoneal cavity with boracic acid solution, and the wound closed without the insertion of a drainage-tube. There was dribbling of urine for a day after the operation; it then became offensive, and was passed frequently with scalding pain. The temperature on the 18th rose to 101·4°, but has been normal since the 20th; on the 21st the urine was clear; on the 23rd the bowels acted naturally; all the sutures were removed on the 24th, when the wound had healed, and the condition of the patient was most satisfactory.

THE INUNDATIONS IN FRANCE.

THE inundations in the south of France have not only caused heavy loss by the destruction of life and property, but serious epidemics may ensue if energetic precautions are not adopted at once. Fortunately M. Lockroy, the Minister of Commerce and Industry, seems to have acted with due promptitude. He has called upon the prefects and mayors of all the districts affected to create a special medical service. The local councils of hygiene were also to be convoked to take extraordinary measures suited to their particular neighbourhood. The general instructions issued are carefully framed, and would doubtless prove effective if rigorously applied. According to these official instructions, the inhabitants must not be allowed to return to their houses till these have been cleansed. A trench should be dug round each house, so as to facilitate the draining away of the water; all the doors and windows must be opened; and wherever organic matter has been deposited within dwellings

by the waters of the flood, the walls, floors, &c., must be scrubbed with a disinfectant; a 5 per cent. solution of sulphate of copper is recommended for this purpose. The walls must be well scraped, and all adhering matter removed. Bedding which has been immersed must, if possible, be destroyed. All well water must be treated as contaminated if near to manure-heaps or cesspits. The bodies of drowned cattle must be buried at once and well covered with quick-lime. Fodder that has been damaged by the floods should either be destroyed or used only for manure. Further orders have been issued forbidding the men employed in such works to commence their labours till an hour after sunrise, or to remain on the spot after sunset. They should also be dressed in woollen materials, never work without first taking food, and the consumption of black coffee should be encouraged. As far as possible the men should be frequently relieved, and made to rest on some elevated spot to the windward of the inundated district. We have not suffered from floods in England to the same extent as have the inhabitants of France, but similar precautions would be useful at home if occasion required. Their application would be on a smaller scale, but none the less beneficial, and we congratulate the French authorities on the wise forethought they have displayed under the present trying circumstances.

CHOLERA IN JAPAN.

Some history of cholera in Japan has recently been published by the Director of the Sanitary Bureau for the empire. According to this authority cholera is known to have appeared in Japan in 1822, commencing at Nagasaki, the only port then open to foreign commerce; and at the same time the disease is known to have prevailed in China. Another epidemic took place in 1858, but no statistical information is available as to either of these outbreaks. But since the empire has been freely open to foreign vessels cholera has been much more frequent. It entered in 1876, and in 1877 it caused 7967 deaths. The next epidemic was in 1879, when 105,786 fatal attacks were recorded. After this there was a cessation until 1885, during the course of which 7152 deaths occurred; and, as we have from time to time noted, the disease has extended into the present year. Cholera is admitted to be, in Japan as elsewhere, generally associated with the prevalence of local filth, and great efforts are being made by the Sanitary Bureau to effect improvements in this respect. Cleanliness, coupled with certain limited quarantine restrictions and the removal of the sick to hospital, are the main remedies relied on.

THE LIMITATION OF INFECTION.

At its meeting last week, the Society of Medical Officers of Health had under consideration two subjects which specially concern the inhabitants of the metropolis—viz., the disinfection of street cabs, and the desirability of contract between the local sanitary authorities and the Metropolitan Asylums Board for the admission into the Board's hospitals of persons suffering from infectious disease and who are not paupers. On the first point the Society readily adopted a resolution to the effect that street cabs which had conveyed cases of dangerous infectious disease should be disinfected by the sanitary authorities without charge; but as to the manner of disinfection there was some difference of opinion. Finally, however, the Society, guided by its president, Dr. Alfred Hill, determined to recommend the use of chlorine. On the second point there was little discussion, the Society being practically unanimous that the adoption of the managers' proposal that the vestries and district boards should contract with them would create serious administrative difficulties. The question, it was feared, would constantly arise as to whether the individual suffering from infectious disease, and whose removal to hospital was sought, was a pauper or not, and as a result he would be bandied from one authority to the other, thus giving rise to serious delay before that removal to hospital would be effected. The obvious course, the Society thought, was that every patient whose disease was certified by a medical practitioner should be removed on the order of the medical officer of health as well as on that of the relieving officer, leaving the charges incurred to fall upon the common poor fund. This irregular method has already been in force in some districts and has worked exceedingly well, and there is no doubt the managers will be aiding in the work of preventing infectious disease if they do not insist too closely on the enforcement of legal requirements. The rest of the evening was devoted to a discussion of papers by Dr. Willoughby on School Lighting and Mr. Mark Judge on the Sanitary Registration of Buildings Bill.

PUBLIC ANALYSIS IN PADDINGTON.

Mr. Alf. W. Stokes, the Public Analyst for Paddington gives in his quarterly report some interesting facts about druggists, and the way they do their work. He seems also to be anxious to have the run of all the private surgeries. He estimates that in London there are 4600 medical practitioners, many of whom dispense their own medicines, and from whom inspectors cannot procure samples for analysis. He admits that, to the honour of the medical profession, mistakes in dispensing are rare, though occasionally dispensers are untrained, and he avers that occasionally an advertisement for the country districts may be seen, "Wanted, a Coachman who can Dispense." Certainly his account of the dispensing by druggists is satisfactory. In no case did he find any ingredient omitted, or one drug substituted for another. Variations in weight of the drugs prescribed were unimportant—the greatest difference being one grain in excess of iodide of potassium, a substance difficult to weigh accurately from its tendency to absorb moisture. Mr. Stokes gives a valuable hint against using tinned meats after the first day of opening them. In one case, brought under his notice by Dr. Danford Thomas, the coroner, death followed the eating of a somewhat stale sample of tinned lobster.

REVISION OF THE MEDICAL CURRICULUM AT MELBOURNE UNIVERSITY.

At a recent meeting of the Senate of the University of Melbourne, certain alterations in the curriculum proposed by the Medical Faculty were received and referred for report to a Committee of the Senate. The changes proposed are of an important character, and if carried into effect will considerably raise the standard of the Melbourne degree. It is necessary that the curriculum should be recognised by the General Medical Council in England. The first proposal is to substitute, in the student's first year, lectures on elementary biology with practical work thrice a week during three terms, instead of structural and physiological botany, and comparative anatomy and zoology. In the first examination it is proposed to examine students in French and German, in addition to the subjects upon which they have been attending lectures, but, seeing that what was demanded was a knowledge of medical literature of these countries, we cannot but agree with Professor Allen as to the undesirability of such an innovation, which would be found impracticable. It appears that at the matriculation Greek and Latin are compulsory, and it would be better to make one or other of these subjects optional, to be replaced by a modern language, than overburden the student in his scientific course with the study of literature. In the second year therapeutics is to be made more elementary, and a first course of dissection is to be compulsory. Advanced thera-

peutics is to be specially taught in the fourth year—an alteration which might well be made in the medical curriculum of the mother country. Obstetric medicine and the diseases of women and children have been taken from the fourth and placed in the fifth year. The final examination will be made more thorough and wide. It is to include medicine, surgery, obstetric medicine and the diseases of women and children, forensic medicine, and the elements of insanity. It is also to be more practical, especially as regards the surgical part of the examination, for heretofore the candidate was simply required to produce a certificate from a surgeon showing that he had a knowledge of the uses and application of instruments and appliances. Hospital practice and teaching is to commence in the second year, so that the student may have two full years of surgery and two of medicine, instead of, as by the previous arrangement, being allowed three years in all for both subjects. Only senior students are to act as dressers, and there is to be a compulsory course of operations on the dead subject and on vaccination—subjects which have been made compulsory for the first time.

A CORONER CONDEMNS MEDICAL CLUBS.

AT a recent inquest at Birmingham, the borough coroner made some unfavourable remarks about the way in which the poor were served who joined medical clubs, on the strength of what happened in the particular case. Here a poor woman, who was a member of the London and Manchester Industrial Insurance Society, sent for the surgeon, Mr. Kenny, at five o'clock in the evening, who could not promise to see her before the morning. Unfortunately she died the same night, and before a surgeon who had been called could see her; he gave as his opinion that if a medical man had seen her at five o'clock she might have been relieved. We regret that the deceased was not seen; but, as we have often pointed out, these industrial associations often expect the impossible of their medical officers, and then pay very little for it. We must blame the associations, and not their unfortunate officers. But, on the other hand, we must not blame all forms of provident medical clubs, where the work is reasonable in amount and is adequately remunerated.

SURGEON-GENERAL W. C. MACLEAN, M.D., C.B.

ON Saturday last (20th inst.) the interesting ceremony of presenting to Mrs. Maclean the *replica* of the original portrait of Surgeon-General W. C. Maclean, M.D., C.B., late Professor of Medicine in the Army Medical School, took place at Dr. Maclean's residence in Southampton. A deputation consisting of twelve subscribers to the Testimonial Fund, headed by Surgeon-General W. S. Murray, Principal Medical Officer at Netley, waited on Mrs. Maclean, and, the deputation having been introduced by the honorary secretary to the Testimonial Committee, the duty of presenting the *replica* was performed in a felicitous speech by Dr. Murray, which was responded to by Mrs. Maclean, who afterwards entertained the company to the number of eighteen at luncheon. On the following Monday the original portrait of Dr. Maclean was presented to the Army Medical Staff Mess at Netley by the honorary secretary to the Testimonial Committee in the name of the Committee, representing subscribers from the Army, Navy, and Indian Medical Services. A large number of ladies and gentlemen who were assembled to witness the presentation were, after the conclusion of the ceremony, entertained at luncheon in the mess-room by Surgeon-General Murray and the officers of the medical staff. The portrait, a three-quarter length by Mr. W. R. Symonds, is an admirable likeness, and in the opinion of spectators does credit to the accomplished artist, who also painted a portrait of the late Sir William Muir, to which it forms an excellent pendant. Surgeon-General and Mrs. Maclean were present, and were warmly congratulated by the numerous friends invited to meet them. The project of a testimonial to Professor Maclean on his retirement after long and honourable connexion with the Army Medical School was only started about eighteen months ago, but was so heartily responded to that within this short time it has been most happily carried out. This portrait will long adorn the walls of the Medical Staff Mess, and be handed down as a heirloom to future generations of medical officers, who, although no longer stirred by the eloquence of the first Professor of Medicine at Netley to go forth with confidence to engage in the contest with disease in tropical climes, will still have the privilege of availing themselves of the valuable results of his experience stored up in his published works.

THE LIABILITY OF FRIENDLY SOCIETIES FOR EXTRA MEDICAL ASSISTANCE.

AN important question for friendly societies is under consideration at Nottingham. The question is this. When a medical officer of a friendly society sends for another doctor, is the latter entitled to claim his fee from the society? The judge in the case at Nottingham County Court has given an opinion in favour of Dr. Collins, who was sent for by Mr. O'Mullane to operate in a case of hernia. According to one witness, the committee had the power to decide in such cases, as to whether the second doctor should be paid. According to another, a patient is entitled to have two doctors of the institution if necessary, and both Dr. Collins and Mr. O'Mullane were officers of the Friendly Societies Medical Institute, of which the patient was a member. We trust sincerely that the judge's ruling will be sustained. The case was one of life or death, and friendly societies should be liberal with medical men in such cases.

CUTANEOUS REFLEX EPILEPSY.

THE remarkable case of epilepsy read before the Medical Society of London by Dr. Hughlings Jackson, and an abstract of which may be found in our columns last week, calls for special consideration. When Dr. Hughlings Jackson, with an experience of such long duration and wide extent in neurology, confesses that he has never seen another case of the kind, the profession will understand that there is something of an altogether unusual character in the case related. To put the matter in a nutshell, it would seem that the case is an almost exact parallel to the epileptic guinea-pigs of Brown-Séquard. In the guinea-pig there is an organic lesion of some part of the nervous system, either induced by a hemisection of the spinal cord or by an injury to the sciatic nerve. In the boy whose case Dr. Jackson related there was persistent left hemiplegia, not absolute, but sufficiently obvious, and, like children's cerebral hemiplegia, associated with diminished growth of the weak and imperfectly used limbs. In the guinea-pig there is an epileptogenous zone, usually limited to one side of the head, and best defined about the angle of the jaw and behind the angle of the eye. In the boy the epileptogenous zone was apparently coextensive with the head and face; it was doubtful whether the one side was more efficient than the other in provoking a fit. The slightest excitation of this epileptogenous area was sufficient to make the boy fall down, with stoppage of respiration and conjugate deviation of both eyes, usually towards the right side. The nervous discharges, Dr. Jackson thought, took place from the grey matter of the pons Varolii and medulla oblongata. He is of opinion that in all cases of epilepsy there is an epileptogenous area situate at some internal or external peripheral surface of the body—that disturbance of the part of the periphery

most especially represented in the "discharging lesion" may provoke a fit. On this luminous theory we may suppose that an epileptic, whose aura is always referred to the gastric distribution of the vagus, may have a fit evoked by gastric derangement, however originated. Clinical experience with us teaches that gastro-enteric disturbances are, if not provocative of a larger number of fits in an epileptic, at all events related in some close and intimate way to an increased frequency and severity of epilepsy. A therapeutical argument may also point the same way, for it is the common experience that some simple medicines directed towards the amelioration of the abdominal organs (such as a mixture of rhubarb and soda) will lessen the number and abate the severity of epileptic attacks. Another interesting feature in the case consists in the fact that if the boy knows that his epileptogenous area is about to be touched the "fit" or "fall" does not occur.

NAVAL MEDICAL SERVICE.

IN an article on "The Royal Navy from the Accession of Her Majesty the Queen," in the *Army and Navy Magazine* for November, Mr. O'Byrne gives a summary of the changes which have been introduced into the medical branch of the service during the last fifty years. From this paper it would appear that during the period included there were no fewer than seven Orders in Council issued regulating the pay, allowances, rank, and retirement of the department generally, besides nine minor ones affecting only certain grades. The Orders in 1855 and 1865 were issued "in consequence of the great and increasing difficulty of obtaining properly qualified medical officers," and some of the others were for the purpose of assimilating the position of the naval with the army surgeon. The paper may be interesting to the past and present medical officers as a brief record of the changes which have taken place in their days, and to intending candidates for the service as affording information regarding the status, pay, rewards, and retirement to which they may look forward in the event of their gaining admission to it.

THE BEAUMONT TRUST.

AT a meeting of the trustees on the 23rd inst. the following resolutions were passed:—"That the Beaumont trustees will not apply for a licence for the sale of intoxicating liquors," and "That on completion of the People's Palace the trustees will open the library and reading-rooms, the swimming-baths, and the grounds of the institution during certain hours on Sundays." This decision must meet with general approval, and it is, we are convinced, in thorough accord with the terms and spirit of the Trust. Without doubt the trustees will meet with opposition in the course they have marked out for themselves, but adherence to their resolutions will gain for them the sympathy and support of all who have at heart the alleviation of the condition of East-end toilers.

INTEMPERATE TEETOTALERS.

THE "Benjamin Hatfield" Lodge of the Original Grand Order of Total Abstinent Sons of the Phœnix appeared to a summons in the Westminister Police-court for withholding £5 from the funeral fund of the lodge, due to the father of a deceased member, named George. The authorities of the lodge refused the money because the deceased, at the instance of his doctor, had taken some port wine, which they alleged was contrary to his undertaking to abstain. The magistrate asked one or two questions which show how shocked he was at the action of some societies. "Was the deceased," he asked, "to abstain perhaps at the cost of his life?" Surely not. "Surely," said Mr. Partridge, "a doctor could order what physic he thought best." He [illegible] in Mr. Partridge to think so, when every week supplies an illustration of the fact that a certain set of teetotalers think that they know more of disease and of the remedies for it than those who devote their lives to the study. The case was not settled by Mr. Partridge, but the defendants agreed to consent to the jurisdiction of the County Court which they had previously repudiated. Such tactics do not advance the cause of true temperance.

THE PERILS OF FOOTBALL.

ANOTHER fatal football accident is recorded. William Colsey, aged twenty-two years, died at Oldbury, on Sunday, from the effects of injuries sustained the previous day whilst playing in a football match between the Langley-green Victoria Club and the Kidderminster Harriers. During a match at Burslem between the Burslem and Bootle teams, A. Simpson came into collision with one of his opponents and had his leg fractured in two places. At Glasgow, on Saturday, Claud Lambie, of the Clyde club, was seriously injured, and at first reported to have succumbed to his injuries, but we are glad to hear this contradicted and that he is on a fair way to recovery. At Stoke-upon-Trent on Monday, during the progress of a football match in which the Stoke and Aston Villa Clubs were engaged, Yates, a member of the latter club, came into violent contact with a player on his own side and fractured his shoulder-blade. At Grantham, on Tuesday, a compositor named Fulbeck, while playing at football, fell and fractured his leg in two places. The game is still only too well described by an old writer as "Footeballe, wherein is nothing but beastlie furie and extreme violence, whereof procedeth hurte." Something will have to be done, and that before long. English monarchs have ere now prohibited and protested against football. It will surely not be necessary in the fiftieth year of the reign of Her Majesty Queen Victoria to suggest repressive measures. The method of playing was not always so rough as that now in vogue. We can endorse the following testimony borne by the writer of an article on sport in a contemporary:—

"Week by week accidents in the football field become more serious and frequent. Without doubt most of the worst are the result of pure accident; but it is quite certain that a proportion of all accidents are the result either of indifference to other players' safety or something much worse. Old footballers who have by chance not assisted as spectators at a match for some years, are almost always struck, when they do renew acquaintance with the pastime, with the unnecessary roughness now practised. All players know that to play the game either according to Rugby Union or Association rules considerable risk must be run. This, in great measure, used to be neutralised by sportsmanlike understanding among the opponents. Nowadays, especially in the Association game, a good deal of the damage is virtually malicious. One of the worst practices allowed is charging a player not on the ball; that accounts for many accidents, and is altogether against the spirit of the game."

Football is too good a pastime to be "ended"; but it is imperative that it be "mended."

THE BROWN INSTITUTION.

PROFESSOR VICTOR HORSLEY, F.R.S., will deliver the annual course of "Brown" Lectures on Dec. 1st, 3rd, 6th, 8th, and 10th, respectively, in the theatre of the University of London, Burlington-gardens, commencing each day at 5 P.M. precisely. The subject of the first two lectures will be the "Pathology of the Thyroid Gland," that of the remaining three being "Epilepsy, the Theories of its Pathology, and Experimental Researches bearing on the

MEDICAL MEN AS CONFESSORS.

THE question of confidence between patient and medical adviser has been again raised, and has been under discussion in the columns of a clerical contemporary, *à propos* the relations between priests (Roman or Anglican) and those who accept them as spiritual directors. We do not think the two functions, that of spiritual and that of medical adviser, are comparable. It is the privilege of our profession to deal with ascertained facts—pathological, physiological, or psychological. We do not of course mean to imply that the subject matters of belief among religionists are not verities. It is outside our province to determine whether they are or not. Towards the peculiar tenets of the various sects the only legitimate position of the scientist as such is agnostic. Meanwhile, all that lies within *our* province is fact, and this we can treat as the data of a profession which is—or ought to be—strictly logical and rational in its aims and influences. We do not think priests should allow themselves to wander beyond the limits of the unknown. Their function is wholly spiritual, and they ought not to deal with the known and material except in so far as it may directly relate to what they conceive to be spiritual. It is neither expedient nor safe for those who are not thoroughly versed in a subject to treat it practically. Morals properly so called are practically outside the ken of the priest in proportion as they are, in a complementary sense, within the province of the physician. Let them leave the physiological moral of life to us. In touching it they play with edged tools, and no wonder if they wound themselves and the sensibilities of their more intelligent friends and disciples.

THE RESULT OF THE SCOTTISH ELECTION.

IT is very satisfactory to us to notice the defeat of the attempt to seize the new seat for Scotland for the Faculty of Glasgow—an attempt which we do not like to characterise. Dr. Bruce of Dingwall has been returned by a good majority. He will have a long way to travel to meetings of the Council, but he is well known and much respected as a practitioner in the extreme north of Scotland, as well as in connexion with the subject of medical education. These are the kind of men that should fill the new seats. We regret that Dr. Sinclair of Dundee should be disappointed, but he will rejoice with us in the election of Dr. Bruce. The numbers of votes were as follows:—Bruce, 661; Morton, 610; Sinclair, 444.

THE ASSOCIATION OF GENERAL PRACTITIONERS.

WE have received a proof of the prospectus of this Association. Its objects are "to advance the interests, support the rights, and promote the welfare of the general practitioner; and especially also to obtain for him a voice in the management of his own affairs upon the various legislative councils of the profession." The names of the officers and council will be found in a letter from the hon. secretaries published on another page.

HYDROFLUORIC ACID IN TUBERCULOSIS.

DR. SEILER has treated tuberculous patients by means of inhalations of hydrofluoric acid. The acid was inhaled once a day for the space of one hour. The process consists of passing the air that is to be breathed through the mixture of acid and water contained in a gutta-percha bottle by means of a pair of bellows. One hundred and fifty grammes of water and fifty of the acid are the proportions of materials contained in the bottle through which the air is forced. The air charged with the vapours of the acid is ejected into the atmosphere of the chamber wherein the patients are sitting. The proportion of vapour is [illegible] ten litres per cubic metre of space. It is [illegible] breath has been relieved after from one to ten sittings; the paroxysms of coughing have been altered in character, so that they become less distressing and of much shorter duration; night sweats disappear after the sittings have extended to fifteen in number; the expectoration is modified; the appetite is regained when previously lost; the weight of the body is increased; the organic and functional derangements of the respiratory passages diminish slowly, it is true, but the amelioration is nevertheless indubitable.

THE ELECTION IN IRELAND.

THE result of the scrutiny of votes for the Irish seat on the General Medical Council had not at the time of our going to press been made known. It was understood, however, that Dr. Kidd's position on the poll was considerably in advance of that of either of his opponents. We are informed that many voting papers were rendered invalid by want of proper care in filling them up; some, for example, having no signature attached to them; others being destitute of the initials of the voter opposite the name of the candidate it was desired to support.

TYPHOID FEVER AT MESSING.

THE sanitary state of the villages of Messing and Tiptree in Essex, is to be brought under the notice of the Local Government Board. In Tiptree diphtheria prevailed last year. But a somewhat serious outbreak of typhoid fever is now prevailing at Messing, and part of it at least is associated with the use of polluted water. The sanitary defects of Messing seem to be very obvious, including nuisances from drains, excreta, and piggeries, besides polluted water. There seems no case for special inquiry when such conditions are well known to exist, and unless the inhabitants wish to make definite complaint of default on the part of the authority, their best plan would be to return as their members such guardians as would secure the needed improvements by the rural sanitary authority.

THE VACANT CORONERSHIP.

PENDING the appointment of a coroner for East Middlesex in place of the late Sir John Humphreys, Dr. Danford Thomas, the coroner for North Middlesex, will undertake the duties of the office. The names of Dr. M'Donald, M.P., Dr. Forbes Winslow, Mr. George Collier, Mr. Wynne Baxter, and Mr. George Hay Young, are announced as candidates for the vacant post.

CHOLERA IN ITALY.

THE prevalence of cholera in Italy as an epidemic is now regarded as at an end. Even in Genoa, whence the latest extension was reported, the disease is rapidly abating. A statistical report recently published in Rome shows that up to the present date the recorded attacks in different parts of the kingdom during 1886 have amounted to 48,000, of which nearly half terminated fatally.

AT the meeting of the Metropolitan Counties Branch of the British Medical Association, to be held at the Jermyn-street School of Mines on Friday evening next, resolutions will be moved protesting against the exclusion of the Apothecaries' Society from the Conjoint Board, and the creation thereby of a new class of competing general practitioners owing no allegiance to the two Colleges. Further resolutions will claim for the Members of the College of Surgeons and the Members and Licentiates of the College of Physicians the right henceforth to a voice in the administration of the Colleges so far as it affects their professional rights and

AT the last meeting of the Liverpool City Council a letter from the Local Government Board was read, in which several alterations in the plans for proposed hospital for infectious diseases were suggested. The committee made known their willingness to meet, as far as possible, these suggestions, and expressed the hope that the Local Government Board would give their immediate consent to the corporation borrowing £15,000 to enable them to proceed at once with the work.

ON the 18th inst., at a meeting of the Northwich Local Board, the medical officer of health reported that, in regard to infant mortality, Northwich compared unfavourably even with Salford. Of the actual death-rate, 46 per cent. were infants under one year of age. This infant mortality indicates the existence of conditions calling for every kind of remedial influence.

AT the Oxford Assizes last week, Mr. Boughton, a medical man, was acquitted of the charge of having criminally assaulted a married woman who had come to his house to request him to visit her husband. We congratulate our *confrère* on successfully proving his innocence of the accusation made against him.

LETTERS received on the 23rd inst. from the West Coast of Africa state that Her Majesty's ship *Racer*, which is now on that station, had been visited by a serious outbreak of fever amongst her officers and crew, no less than twenty-five, amongst whom was the doctor, being attacked, some of them seriously.

THE death is announced of Dr. Albert Burckhardt-Merian, Professor of Otology in the University of Bale. The deceased, who was only forty-four years of age, had for a long time suffered from a painful malady.

DR. D. FRANCISCO TORRALBAS Y MANRESA has been appointed to fill the vacancy in the Supreme Sanitary Council of Cuba, caused by the death of Professor Vargas Machucha.

THE death is announced of Dr. D. Pedro Martinez Sanchez, formerly professor in the Medical Faculty of the University of Habana.

THE Russian Order of St. Stanislaus (1st Class) has been conferred on Professor Leyden of Berlin.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chelsea.—Dr. Seaton's annual reports to the vestry of Chelsea bid fair to constitute an interesting chapter in the history of the health of the metropolis, dealing as they do with important matters affecting the community as a whole, in addition to constituting a record of health in the parish primarily concerned. During 1885 the birth-rate of Chelsea was 34·6 per 1000, and the death-rate 21·7. Under five years of age the mortality is seen to be about the same as that of the English Life Table, whereas in some provincial towns the rates for the same period of life are in excess of that in the Table by as much as from 15 to 20 in the 1000. The causes of this excessive rate in the textile manufacturing districts are stated to arise, in the main, from the deplorable maternal neglect of infants. Diphtheria produces a large amount of death in Chelsea, and we fancy Dr. Seaton goes a little beyond the lines which should limit him by enforcing his conclusion that defective house-drainage has [illegible] to do with the production of the disease. It is true, as he says, that the disease is more fatal in country districts than in towns, whereas drain nuisances are more common in the latter; and we do not doubt the fact, recently reported by a Government inspector, that in Tottenham less than 20 per cent. of the houses affected by this disease had any definite sanitary defects. But this hardly justifies the belief "that defective house drainage and diphtheria cannot be said to stand in the relation of cause and effect." The fact is that diphtheria, once prevalent, tends to spread, in the main, by means of personal infection, and hence in by far the majority of cases the question of house sanitation becomes a secondary one as regards causation, when once the infection has been set on foot; but the earliest attacks are, we believe, often associated with defective sanitary circumstances, and it appears to be the very existence of such circumstances that often determines the question whether a given sore-throat shall remain a simple one, or shall put on those characters, including infectiveness, that specialise diphtheria. In the latter part of his report, Dr. Seaton enters at considerable length into the question of the special fatality of small-pox in the metropolis as compared with the provinces, and he publishes some interesting statistics showing how large the incidence of that mortality is on London. He is evidently desirous of impressing on his readers the fact that, in the matter of small-pox in London, measures of prevention do not take the same high rank as they would in a provincial town, and he refers to the so-called "success" of the Metropolitan Asylums Board, which means that they have managed to receive into their hospitals great numbers of the sick, whereas provincial sanitary authorities, aiming above all things at prevention, would only regard their action as successful when they had been able by the several means adopted including isolation to prevent the occurrence of large number of cases. When we remember that in London the guardians of the poor see to vaccination and revaccination, the vestry look after the disinfection of the affected premises and clothing, and the Metropolitan Asylums Board have to isolate the patients, the wonder is that we manage as well as we do. Dr. Seaton in this portion of his report suggests as a suitable question for discussion—"Since the establishment of the present system of so-called 'isolation' and treatment of small-pox in hospitals established by the metropolitan poor authority, has small-pox diminished or increased in London?" Here he touches the kernel of the matter he has been discussing. We have often contended that the answer is to the effect that there has been an increase, and we believe that the points of difficulty involved in the question cannot be much longer shelved.

Hampstead.—According to Dr. Gwynn's report, the year 1885 exhibited the lowest death-rate but one that is on record in St. John's, Hampstead—namely, a rate of 11·5 per 1000. Scarlet fever caused some mortality in the district, the outbreak being due to the infection of milk in connexion with the Marylebone outbreak, which was investigated by Mr. Power and Dr. Klein. The epidemic of small-pox in the metropolis, which ceased in the latter half of last year, mainly affected Hampstead between May, 1884, and July, 1885. During the latter year 59 cases were recorded in Hampstead. The area within a quarter of a mile of Hampstead Hospital contributed 13 cases, between a quarter of a mile and half a mile there were 3 cases, and between half a mile and a mile there were 18 cases. In July, 1885, the managers of the Asylums Board, apparently recognising the danger which the metropolitan hospitals constituted, resolved on moving cases direct to the hospital ships at Long Reach. The Hampstead Hospital was then closed, and this step is reported to have been associated with the termination of the epidemic in Hampstead. The Housing of the Working Classes Act, 1885, in so far as it brings tents, vans, &c., used by gipsies and others under inspection and sanitary control, has been found to be very useful in dealing with an encampment near Platt's-lane. A Ransome disinfecting stove, which was erected some time back, has unfortunately been destroyed by fire. The stove is fitted with an apparatus intended to work automatically, which shall prevent excessive heat, and even extinguish a fire which may commence. It appears to have failed, and the apparatus has now been replaced by a Washington Lyon's high-pressure steam disinfector. We may note that whenever hot air is used as a means of disinfection it is important to turn all pockets inside out, for there is reason to believe that when [illegible] occurred during the process, this has [illegible] being left in some coat pocket.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6098 births and 3320 deaths were registered during the week ending Nov. 20th. The annual death-rate in these towns, which had been 18·2 and 19·5 per 1000 in the preceding two weeks, declined again last week to 19·1. During the first seven weeks of the current quarter the death-rate in these towns averaged 19·0 per 1000, and was 2·2 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 13·8 in Portsmouth, 14·3 in Brighton, 15·9 in Birmingham, and 16·8 in Nottingham. The rates in the other towns ranged upwards to 24·9 in Bolton, 26·4 in Blackburn, 27·1 in Leeds, and 27·8 in Norwich. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 368 and 411 in the preceding two weeks, declined again last week to 402; they included 103 from measles, 95 from scarlet fever, 62 from diarrhœa, 54 from "fever," 49 from whooping-cough, 39 from diphtheria, and not one from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Nottingham, Bolton, Birkenhead, and Cardiff; while the highest rates occurred in Blackburn, Leeds, and Wolverhampton. The greatest mortality from measles occurred in Leeds, Halifax, and Wolverhampton; from scarlet fever, in Bristol, Hull, Salford, and Blackburn; from "fever," in Blackburn; and from whooping-cough, in Huddersfield and Sunderland. The 39 deaths from diphtheria in the twenty-eight towns included 26 in London, 3 in Portsmouth, 3 in Liverpool, and 3 in Manchester. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 293 and 321 in the preceding two weeks, further rose last week to 346, but were 104 below the corrected average. The causes of 75, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Blackburn, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Sheffield, Bolton, Oldham, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·1 and 20·1 per 1000 in the preceding two weeks, rose again to 21·4 in the week ending Nov. 20th; this rate was 2·3 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·2 in Greenock and 15·5 in Leith, to 23·7 in Glasgow and 27·8 in Paisley. The 529 deaths in the eight towns last week showed an increase of 32 upon the number in the previous week, and included 24 which were referred to scarlet fever, 19 to diarrhœa, 19 to whooping-cough, 6 to "fever" (typhus, enteric, or simple), 5 to diphtheria, 4 to measles, and not one to small-pox; in all, 77 deaths resulted from these principal zymotic diseases, against 73 and 81 in the preceding two weeks. These 77 deaths were equal to an annual rate of 3·1 per 1000, which was 0·8 above the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of scarlet fever, which had been 24, 16, and 23 in the previous three weeks, rose again last week to 24, of which 16 occurred in Glasgow, 2 in Edinburgh, 2 in Dundee, 2 in Aberdeen, and 2 in Paisley. The 19 deaths attributed to diarrhœa showed a decline of 2 from the number returned in each of the preceding two weeks, and included 6 in Glasgow, 5 in Dundee, and 3 in Edinburgh. The deaths from whooping-cough, which had been 15 and 17 in the previous two weeks, further rose last week to 19, of which 17 occurred in Glasgow. The fatal cases of "fever" and of diphtheria were fewer than the number in the previous week; 3 of "fever" occurred in Glasgow and 2 of diphtheria in Edinburgh. Three of the 4 deaths from measles were returned in Aberdeen. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had increased in the preceding four weeks from 79 to 123, further rose last week to 137, but were 4 below the number in the corresponding week of last year. The causes of 75, or more than 14 per cent. of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 26·2 and 23·6 per 1000 in the preceding two weeks, rose again to 24·5 in the week ending Nov. 20th. During the first seven weeks of the current quarter the death-rate in the city averaged 23·2; the mean rate during the same period was 17·2 in London and 18·9 in Edinburgh. The 166 deaths in Dublin last week showed an increase of 6 upon the number in the previous week, and included 10 which were referred to scarlet fever, 4 to diarrhœa, 3 to "fever," (typhus, enteric, or simple), 2 to whooping-cough, 1 to diphtheria, and not one either to small-pox or measles. Thus 20 deaths resulted from these principal zymotic diseases, showing a further decline from the 32 and 23 returned in the previous two weeks; they were equal to an annual rate of 3·0 per 1000, the rates from the same diseases last week being but 1·9 in London and 1·6 in Edinburgh. The fatal cases of scarlet fever, which had been 10, 8, and 15 in the preceding three weeks, declined again last week to 10. The deaths from diarrhœa showed an increase of one, while those of "fever" and whooping-cough corresponded with the numbers in the previous week. Three inquest cases and six deaths from violence were registered; and 56, or more than a third, of the deaths occurred in public institutions. The deaths both of infants and of elderly persons showed a considerable increase upon the numbers in the previous week. The causes of 23, or nearly 14 per cent., of the deaths registered during the week were not certified.

VITAL STATISTICS OF QUEENSLAND.

The Registrar-General of Queensland has issued his twenty-sixth annual report on the vital statistics of that colony, dealing specially with the figures for 1885. The estimated mean population of Queensland during last year was 318,415 persons, in the proportion of 59 males to 41 females. This estimate is calculated by the addition to the enumerated population of 1881, of the annual increase by excess of births over deaths and by excess of immigration over emigration. Censuses are taken in Queensland quinquennially, therefore the report for the current year will be based upon the results of the enumeration which was taken on the night of May 1st last. The population of this colony includes, it should be stated, more than 12,000 Chinese, of whom only 49 were females, and nearly 11,000 Polynesians, including only 1000 females. This fact appreciably affects the proportion of males to females, as well as the marriage, birth, and death rates. The report shows that the marriage-rate of the Queensland population was equal to 17·86 persons married per 1000, scarcely differing from the recorded rates in the preceding two years, and considerably exceeding the rates in any of the other Australasian colonies. It is pointed out that the proportion of signatures to the marriage register shows a further improvement in the educational standard of the population. The birth-rate of the population was 36·66 in 1885, or, if the Chinese and Polynesians be excluded from the calculation, the birth-rate was equal to 39·62 per 1000. The death-rate was 19·58 per 1000 in 1885, against rates increasing steadily from 13·59 in 1880 to 22·97 in 1884. Again, if we exclude the Chinese and Polynesians the death-rate becomes 17·06 for 1885, and, as affording a standard for comparison, it is pointed out that in six of the Australasian colonies the death-rate in 1885 ranged from 10·61 in New Zealand to 17·75 in Western Australia. The recorded mortality of the Polynesians reached the terribly high figure of 98·84 per 1000, as compared with 147·74 in 1884; among the Chinese, however, this rate did not exceed 7·63 in 1885, against 8·13 in 1884. The more than decimating mortality among the labourers imported from the Pacific Islands affords the most conclusive argument against this kind of labour traffic. Infant mortality in Queensland was equal to 14·85 per cent. of the registered births, showing a further increase upon the proportions in preceding years. With regard to the causes of mortality, the death-rates from the various diseases require correction for the abnormal age-constitution of the population. For instance, the death-rate from phthisis is given as 1·86 per 1000, but this figure would bear still more favourable comparison with the rates from this disease in European countries if correction were made for the exceptionally large proportion of young adults in the population. Again, the high death-rate from diarrhœa, 1·14 per 1000, is probably in part due to the large proportion of young children in the population. From a [illegible] point of view, the most unsatisfactory feature of [illegible] is [illegible] enabled [illegible]

the report is a death-rate of 1·41 per 1000 from "fever," including typhoid and simple or undefined fever. The report, on the whole, is to be commended for its excellent treatment of the varied statistics with which it deals.

THE SERVICES.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Staff Surgeon Alexander Flood has been allowed to withdraw from Her Majesty's Naval Service, with a gratuity.

The following appointments have been made: Fleet Surgeon R. Hay, to the *Eagle;* Fleet Surgeon W. D. Wodsworth, to the *Minotaur;* and Fleet Surgeon J. P. Courtnay to the *Devastation.*

YEOMANRY CAVALRY.—Westmoreland and Cumberland: Thomas Drummond Sanderson, Gent., M.D., to be Surgeon.

ARTILLERY VOLUNTEERS.—3rd Middlesex: Surgeon and Honorary Surgeon-Major E. G. Purcell, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement.

RIFLE VOLUNTEERS.—2nd Cambridgeshire (Cambridge University): Surgeon E. Carver resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the corps on his retirement.

Correspondence.

"Audi alteram partem."

THE APOTHECARIES' SOCIETY AND THE CONJOINT SCHEME.

To the Editor of THE LANCET.

SIR,—The Apothecaries' Society by its action under the present crisis is setting an example to all corporate bodies; it has sunk all private and selfish interests, and is appealing to its licentiates throughout the kingdom to express their opinions on the point at issue—whether to still endeavour to obtain its proper and legitimate position in the Conjoint Examining Board, or whether to obtain powers from the Privy Council to institute a complete examination entitling to practise in all branches. The Society has thus broken the ground in seeking counsel from its members, and the time is not far distant when the Royal Colleges of Physicians and Surgeons will have to do likewise. It seems preposterous that in the year 1886 an important question like the present, affecting the whole community, should be settled by a small sub-committee of the two Colleges, by men who have little in common with the general practitioner, and who know very little of the public requirements, but yet who, through their exalted position in the profession, have great power for good or evil. The time has now come when those in high places should hear the other side of the question from the general body of the profession, who on this particular subject are far more able to give a better opinion and sounder advice. Trusting that all members of the profession will shake off their apathy on this occasion (which I think they are doing, from the letters I am receiving), and join heart and soul in supporting the Society of Apothecaries during their present struggle,

I remain, Sir, yours truly,

Nov. 24th, 1886. J. WICKHAM BARNES.

To the Editor of THE LANCET.

SIR,—I cannot say how pleased I was to read the letter of "L.S.A., &c.," in your last issue. He asks, "Is not an L.S.A. (*solus*) a practitioner of an inferior grade?" Inferior to what? I presume a surgeon. My answer is, "Certainly not." An apothecary, on historical grounds, is higher than a surgeon. I will try to prove this. If your correspondent will go to the British Museum, he will obtain access to a scarce and most interesting book entitled "Memorabilia," written by Mr. Wadd, surgeon to William IV. Let him turn to page 9. He will there read, "1617, Society of Apothecaries made independent of the Grocers." Let him turn to page 52, he will find "Edward III. in the year 1461 granted the Charter of Incorporation to *Barber*-Surgeons, and the barber and surgeon continued in the same firm for *three centuries.*" Further, Mr. Pott, the eminent surgeon, after their separation, "being desirous of exercising his franchise, presented himself as a barber-surgeon liveryman. 'No, no,' said the scrutineer, 'you may still be a *shaver*, Mr. Pott, but you have not been a barber these five years.'" "Would heart of man e'er think it?" said Abernethy; "even I myself have doft my cap to barber-surgeons." That is to say, whereas the apothecaries repudiated the grocers as far back as 1617, the surgeons were associated with hairdressers and shavers till 1761.

The fact is the College of Physicians has made a blunder. They, to be consistent, should have said to the surgeons what they now say to the apothecaries: "Inasmuch as the examination conducted by the Royal College of *Physicians* of London, is a complete qualifying examination in medicine, surgery, and midwifery, conferring the right of registration under the Medical Act, ... a combination with the College of Surgeons is unnecessary." The proper persons to amalgamate with the apothecaries is, on historical grounds, the surgeons; and the physicians having created a precedent by an "unnecessary" combination with the surgeons, they can (and should) extend the same hand to the equally important apothecaries. In any case the "Hall" is master of the situation. They can exercise their undoubted rights of preventing physician and surgeons and unqualified persons from practising *pharmacy*—i.e., selling medicine to patients at a profit; and they can also refuse to protect the practices of persons who do not hold their licence from the incursions of quacks.

I am, Sir, your obedient servant,

Nov. 18th, 1886. "YE HUMBLE APOTHECARIE."

To the Editor of THE LANCET.

SIR,—Looking at the important position that the Apothecaries' Society is likely to hold in the future as a separate examining body, would it not be a graceful act if in the year of Jubilee it promoted all its licentiates of ten or fifteen years' standing, upon payment of a nominal fee, to the degree of members? Such a step would not only give great satisfaction, but also prove a financial success. Hoping this suggestion may call forth the opinions of other licentiates,

I am, Sir, yours obediently,

Nov. 1886. L.S.A.

ASSOCIATION OF GENERAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—Will you allow us to state, in answer to inquiries which have been made, addressed to us in reference to the letter which you were good enough to publish in your columns of last week, that this Association has been formed for the purpose of advancing the interests and supporting the rights of the practitioner, and that in now taking steps to enlarge its organisation we are acting in no spirit hostile to any existing association, but desire to afford the practitioners a platform from which to maintain their own interests and those of the profession in relation to the great body of practitioners and their public and personal duties and rights. Among the work already in progress is the organisation of meetings to consider the course recently pursued by the Royal College of Surgeons and Royal College of Physicians in excluding the Apothecaries' Society from combination in the joint examining board for England and Wales; thus, without any consultation with their Members and Licentiates, creating under the Medical Act of 1886 a new and competing class of general practitioners, fully qualified as they will be under this Act by the Apothecaries' Society in medicine and surgery, and taking medical and surgical titles. Under any circumstances, it seems to us that in so momentous a matter, affecting deeply the interests of the whole body of general practitioners, they had a right to be consulted. We, in common we believe with the great body of the profession, feel that general practitioners ought no longer to be excluded from a voice in the management of their own affairs, but it is only by combination and force, which association gives, that they can assert those rights and give them effect. Self-help lies at the basis of independence, freedom, and just principles, and it is only by combination that general practitioners [illegible] themselves from having their work

momentous interests dealt with by small and irresponsible councils, self-elected, or elected by some small constituency, of which the general practitioners, who form the immense majority of the profession, and who are the backbone, have no share. We should add that Mr. C. G. Wheelhouse of Leeds has consented to act as president, and that Dr. Alfred Carpenter (Croydon), Dr. Dolan (Halifax), Mr. Hugh Massey, Mr. George Ord (Brixton-hill), Mr. Wickham Barnes, Dr. Danford Thomas, Dr. Richard Paramore, Dr. Richard Neale, Mr. G. W. Crowe, Dr. Morris (Spalding), Mr. Gubb (London), Mr. Corner (Poplar), and Dr. Maurice Davis, are among the first members of council. It has not been thought advisable to complete the list of officers at this comparatively early stage of proceedings, but these names, among others, will afford adequate assurance that our objects and methods of proceeding will be guided by a single eye to the welfare of the profession.

We earnestly hope to be favoured by the personal adhesion of all who concur in these views.

We are, Sir, your obedient servants,

H. WALTER VERDON,
410, Brixton-road, S.W.
W. GIBSON BOTT,
414, Clapham-road, S.W.

Nov. 1886.

THE MICRO-ORGANISM OF BERI-BERI.

To the Editor of THE LANCET.

SIR,—Having read in the *Medical Press and Circular* of July 28th that Dr. Wallace Taylor, in Japan, has recently discovered in the blood of many sufferers from kakké, or beri-beri a micro-organism which he cultivated and inoculated, or administered internally, in monkeys, rabbits, rats, dogs, &c., producing in these animals the symptoms of kakké, and as it appears that these facts have been received as a novelty, I judge it my duty to recur to your journal to show that such facts, demonstrative of the cause of beri-beri, have already been produced by me in Brazil since 1883. I not only isolated the micro-organism from the blood of beri-beri patients, but cultivated it according to the methods of Koch and Pasteur, and, inoculating it in animals such as monkeys, rabbits, and guinea-pigs, I saw appear in these animals the symptoms of beri-beri, all dying after a greater or less time. Proceeding afterwards to a histological study of the viscera by the methods of colouring of Weigert and of Gram, I demonstrated the existence of the same micro-organisms in great quantities in the nerves, spinal medulla, heart, liver, spleen, and kidneys. In 1883 I published my first paper on the subject under the title of "Etiologia et Genesis de Beri-beri," which was the subject of a verbal communication to the Academy of Medicine of Paris by Dr. Jules Rochard, in the session of Jan. 29th, 1884. The *Journal d'Hygiène* of Paris of Feb. 7th, 1884, published a leading article on the subject of that communication, giving at the same time an analysis of my work. In order to continue my investigations on beri-beri, I shall start in a few days, at the head of an official commission, for the northern provinces of the empire—the principal centres of the disease in Brazil.

In presenting these facts and documents, Mr. Editor, I have only in view to save my right of priority in the discovery of the true cause of beri-beri.

I remain, Sir, your obedient servant,

J. B. DE LACERDA,
Director of the Laboratory of Experimental Physiology at the *Museo Nacional* of Rio de Janeiro.

Rio de Janeiro, Oct. 27th, 1886.

THE SANITARY SCIENCE CERTIFICATE AS AN ADDITIONAL REGISTRABLE QUALIFICATION.

To the Editor of THE LANCET.

SIR,—I see the Medical Council have been occupied in discussing the desirability of having a uniform title for the certificate in Sanitary Science, so as to register the same as an additional qualification. I do not think their time was unprofitably spent in doing so. I think it is desirable to have some uniformity in registering this qualification, and would suggest that Sanitary Science Certificate is the most convenient and the most elegant form. Certificate in Public Health does not abbreviate so easily; and besides, we have already the first term in common use for the Cambridge Sanitary Science Certificate holders: Mr. [illegible] Camb.; S.Sc.C. R.C.P. Lond. or Edin., as the case may be; S.Sc.C. Fac. Glasg., or S.Sc.C. F.P.S. Glasg., and S.Sc.C. Durham. All these are much neater than Cert. Pub. Health Lond., or R.C.P. Lond., as the case may be. Then for the B.Sc. Edin. or Glasgow, you would have it as follows: B.Sc. Ed. (S.Sc.), or B.Sc. (S.Sc.) Edin. There would be no difficulty for the corporations to change their certificate from Public Health to one of Sanitary Science; and we have the additional advantage of the Cambridge men using this form for the last ten years.—I am, Sir, yours truly,

Wigan, Nov. 22nd, 1886. WM. BERRY.

THE CHARTER OF CHARLES I.

To the Editor of THE LANCET.

SIR,—It appears that some Members of the Royal College of Surgeons of England believe that they have a right to the collegiate electoral franchise under the provisions of the Charter granted by Charles I. in 1629 to the Company of Barbers and Surgeons, and that this right has since then been, and still is, unjustly withheld from them. From this reading of the Charter I entirely dissent. But the point is a purely legal one—for lawyers, and not for medical men, to decide upon. I would therefore suggest, as the most reasonable way of speedily and definitely settling this question, that those Members who believe that they are entitled to this right under the Charter of the 5th Charles I. should petition the Council of the College to take counsel's opinion on this point, or, better still, should institute a friendly suit against the College for the restitution of the alleged right.

I am, Sir, yours &c.,

Nov. 20th, 1886. JOHN ERIC ERICHSEN.

THE DENTAL CURRICULUM.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me in your pages to call the attention of all those interested in dental education to the recent decision of the Council of the Royal College of Surgeons, which materially affects the dental curriculum. At the last meeting of the Council it was resolved, on the recommendation of the Dental Board, that eighteen months of the three years' mechanical work required of candidates for the "L.D.S." may be taken before registration as dental students—i.e., before the preliminary examination has been passed. It, however, makes no change with regard to the four years' professional work required in the schedule, which must still be taken subsequently to registration. Under the old regulation the three years' mechanical work had to be taken subsequently to registration, and candidates who had through error done that work previously to passing the preliminary examination had to do it over again, but now one half of it will be recognised and the other half only has to be taken after registration. This is an important concession, and affects a large number of dental students, and will enable in the future those candidates who are unsuccessful at their "preliminary" to proceed with their apprenticeship during the time they are preparing themselves for re-examination.

I am, Sir, your obedient servant,

MORTON SMALE.

Dental Hospital, Leicester-square, Nov. 21st, 1886.

THE ENGLISH CONJOINT BOARD.

To the Editor of THE LANCET.

SIR,—In your editorial note to my letter in your issue of Nov. 13th, page 949, you say: "A student can pass his final examination in three years and a half after entering a medical school." The rules do not permit a student to enter for his second examination until he has spent eighteen months' professional study at a medical school; and these are sessional months, and take up two winter sessions of six months each, and two summer sessions of three months each, or, together, two educational years. These two years must elapse before the student can go up for his final examination, thus making four years' study at a medical school. This any student can do who goes direct to a London school at the commencement of his studies. We contend that a first year spent in work as dresser at a large provincial hospital, during which time he gets more practical [illegible] four-fifths of the London dressers is worthy of

recognition; and we complain that this, which has hitherto been allowed by the College of Surgeons, has been suddenly and arbitrarily taken away from us, and with it the inducement for students to come here. The recommendation of the Conjoint Board for students to do this work in the middle of their course of study in London is impracticable, and would be discountenanced by their London teachers.

I am, Sir, yours truly,

Southernhay, Exeter, Nov. 17th, 1886. JAS. BANKART.

*** Eighteen months do not mean sessional months, but two winter and one summer sessions. The time spent before entering a medical school may be most profitably employed in a provincial hospital, where, in addition to practical dressing, a student can be taught chemistry, botany, materia medica, and pharmacy.—ED. L.

THE L.S.A. QUALIFICATION.

To the Editor of THE LANCET.

SIR,—With your permission I should like to put a question to "L.S.A. (with other qualifications)."

What proportion do L.S.A.'s bear to the M.D.'s, M.R.C.S.'s, L.R.C.S.'s, L.R.C.P.'s, &c., who are flooding the country with sixpenny, ay, fourpenny, dispensaries? When he has ascertained this fact, I think he will have less difficulty in making up his mind about the "inferior grades" in the profession.

I am, Sir, yours truly,

Nov., 1886. L.S.A. (with no other qualifications).

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

TYNEMOUTH INFIRMARY SCHEME.

AN Art and Industrial Exhibition in aid of the funds of the projected infirmary at Tynemouth was opened last week under favourable auspices. The Mayor presided. It was stated to be the intention of the Duke of Northumberland to grant a site for the erection of a building, and before the meeting separated the member of Parliament for the borough (R. S. Donkin, Esq.) headed the subscription list with 200 guineas.

THE VOTING FOR THE MEDICAL COUNCIL.

We were rather surprised to hear that there was a prospect of a light poll, seeing that, in the north at least, the greatest interest has been taken in the election from the very first, and I believe that by to-day (the 22nd) very few papers of northern voters—I mean from the large centres, such as Newcastle, Sunderland, &c.—will have failed to reach the office of the Medical Council. Still the result will be looked for here with curiosity, and yet with a confidence that in our voting we have all done our best in the broad interests of the profession.

CURIOUS POOR-LAW CASE.

At a late meeting of the Tynemouth Board of Guardians one of the relieving officers brought a rather peculiar case under the notice of the Board. It is that of a master mariner who died early in this year, leaving £355 3*s.* 1*d.* cash in the National Bank of Scotland, and also considerable property in the Orkney Islands. In 1863 his wife was removed from North Shields to the Morpeth Lunatic Asylum, and is now a resident therein. Over a period of twenty-two years the Tynemouth guardians have been responsible for her maintenance. Her husband, however, willed the whole of his estate to a niece and nephew. On learning these facts, the officer, on the part of the guardians, laid claim for the maintenance of the wife, and as the executor had not put in the usual statutory notices, it was considered that the guardians had a good case at law, and they gave directions to have it presented. The amount due to the guardians will be considerable, based on her average cost of 11*s.* per week for maintenance ranging over twenty-three years.

SCARLATINA AT WALKER.

At a late meeting of the School Board it was mentioned that sixty-six children were absent, either suffering from scarlatina or having it in their homes. Mr. Hurst, surgeon, stated he had conclusive proof of the insanitary [illegible] of one of the schools by the presence of rats on the premises, which, as he pointed out, was a proof of connexion with sewers, and that consequently bad smells and sewer-gas would exist.

NEWCASTLE JUBILEE EXHIBITION.

It may interest many of your readers to learn that up to the present considerable progress has been made with the buildings required for the Jubilee Exhibition to be opened next year in Newcastle-on-Tyne. At a late meeting of the Council, the necessity of extending the space was considered and decided upon. A letter was also read from the treasurer of the Prince of Wales, stating that it would give his Royal Highness much pleasure to send from his collection several works of art to the Exhibition.

BATHS AND EPILEPTICS.

A sad event took place this week in one of our suburbs, by which a young lady aged nineteen, who was subject to epilepsy, lost her life in a bath. When discovered, she was quite dead, and had evidently had a fit and had been suffocated in about two pailfuls of water.

Newcastle-on-Tyne, Nov. 22nd.

EDINBURGH.

(*From our own Correspondent.*)

THE LATE DR. A. H. BALFOUR.

EDINBURGH has lost one of its best-known general practitioners by the sudden death of Dr. Balfour of Portobello, which took place last week. Dr. Balfour settled in Edinburgh nearly forty years ago, after gaining a wide experience of practice in Oriental countries; and ever since he has been known here as a most successful and much-esteemed medical practitioner, and as an influential citizen. Of late years he has been assisted in his extensive practice by his two sons, Drs. A. H. and J. H. Balfour.

UNIVERSITY LECTURES ON BIOLOGY.

Mr. G. J. Romanes commenced this week his annual course of six lectures on the Philosophy of Natural History, which has received the title of the Rosebery Lectures, from the lectureship having been endowed by the late Foreign Secretary. In the present course Mr. Romanes proposes to trace the history of biological speculation from the earliest times down to that of Charles Darwin. The opportunity of hearing so interesting a topic ably discussed has been embraced by a numerous body of students, and in that respect the new lectureship may be pronounced an entire success.

Edinburgh, Nov. 23rd.

ABERDEEN.

(*From our own Correspondent.*)

THE ROYAL INFIRMARY.

IN the Bill to be brought before Parliament in the forthcoming session, the managers of the infirmary seek powers "to rebuild, remodel, or alter the existing infirmary, asylum, and convalescent hospital buildings, or to erect and manage new infirmaries, asylums, or dispensaries for the cure of the sick in mind or body," and to provide for the inclusion, under the new Corporation, of all such institutions already established, or hereafter to be established, in Aberdeen, and in particular the Hospital for the Relief of Incurables, the Ophthalmic Institution, the Dispensary, and the Hospital for Sick Children. The directors of the Dispensary, at a meeting held to consider this proposal, declared against the amalgamation of the Dispensary and Infirmary, because they were of opinion that the two institutions would best fulfil their functions apart. It has been suggested that Aberdeen would best celebrate the Queen's Jubilee by building a hospital worthy of the city, and it is rumoured that two gentlemen have promised to subscribe £15,000 for this purpose. When appointed Assistant Physician to the Infirmary, Dr. Blaikie Smith resigned the office of [illegible] to the institution, which he held [illegible] MacGregor, and Buxton are

candidates for the vacant post, which is to be filled up at the quarterly meeting of managers in December. The fact that this appointment is in the hands of the general managers, numbering between 300 and 400, is one of the many examples of the absurd manner in which the institution is at present managed.

THE HOSPITAL FOR INCURABLES.

At a meeting of the Committee of Management held on the 18th inst., Dr. George Edmond was appointed Physician to the Hospital for Incurables, an office rendered vacant by the death of Professor Dyce Davidson. Before proceeding to the appointment the Committee, on the motion of the Chairman, resolved to record their sense of the great loss the institution had sustained through the death of Dr. Davidson, who for upwards of thirteen years had discharged with unvarying courtesy and kindness the duties of medical officer to the hospital; and they directed an extract of the resolution to be transmitted to Mrs. Davidson as an expression of their sympathy with herself and her son.

THE MEDICO-CHIRURGICAL SOCIETY.

At the annual meeting of the Medico-Chirurgical Society, held on Thursday, the 18th inst., the following office-bearers were elected for the ensuing year:—President, Dr. Rodger; vice-president, Dr. Smith-Shand; secretary, Dr. George Edmond; recording secretary, Dr. Macgregor; treasurer, Dr. Beveridge; librarian, Dr. William Fraser; members of council, Drs. Booth, Garden, Gordon, Jackson, and Struthers; representatives to the North of Scotland Medical Association, Drs. M'William and Theodore Thomson.

Aberdeen, Nov. 26th.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

THE Senate at a recent meeting enacted that the following regulations concerning the courses of medical studies for degrees in this University shall come into operation in the autumn of next year:—1. Medical students shall not enter upon their regular professional studies until the completion of their obligatory non-professional studies. 2. The *first year's* course of medical studies shall include Natural Philosophy, taught experimentally; Systematic and Practical Chemistry; Botany, a three months' course; Zoology, six months' course. 3. Students who have already taken the degree of A.B. in any of the subjects named for the first year's course of medical studies shall, upon the production of the necessary certificates, be exempted from attending any further lectures or passing examinations in such subject or subjects; and any such students who have passed in Natural Philosophy, Systematic and Practical Chemistry, and Biology, shall be reckoned to have completed the first year's course of medical studies, and shall be entitled at once to enter upon the second year's course of medical studies. 4. The *second year's* course shall include Systematic and Practical Anatomy, Systematic Physiology, Pharmacology (Materia Medica), and attendance at a medico-chirurgical hospital for six months. 5. In the *third year* the medical studies shall comprise Advanced Systematic and Practical Anatomy; Advanced Systematic and Practical Physiology and Histology; Medicine, including Therapeutics and Pathology; Surgery, including Therapeutics and Surgical Pathology. 6. The *fourth year's* studies shall comprise the remaining subjects of the medical curriculum, viz.—Midwifery and Diseases of Women and Children; Mental Diseases, three months' course; Medical Jurisprudence, with Hygiene; Ophthalmology and Otology, three months. 7. The examination for the M.B. degree shall take place at the conclusion of the fourth year of medical studies, and will comprise all the subjects prescribed above for the third and fourth years of medical studies, with the exception of Anatomy and Physiology and Histology. 8. Candidates for the degree of Master of Surgery must have attended a course of operative surgery. In future candidates, prior to admission to the first examination in medicine, will be required to produce a certificate of their registration as medical students.

DUBLIN HOSPITALS COMMISSION.

Many months ago this Commission [illegible] week after week it was thought that [illegible] the Commissioners. Month after month, however, has gone by, and now, when the subject has almost faded from the minds of those interested in the matter, it is stated that the report is nearly ready, and will shortly be issued. It is rumoured that the Commissioners have recommended that the Government grant shall in future be distributed *pro rata* among the several hospitals in the city.

DUBLIN UNIVERSITY BIOLOGICAL ASSOCIATION.

The opening meeting of the winter session was held last week in the Museum-buildings, Trinity College, presided over by Dr. C. B. Ball. The inaugural address was delivered by the incoming president, Mr. Cunningham, the subject being "Muscular Homology." The variations which occurred in muscles were, he thought, indications either of advance or retrogression. According to the Heidelberg school, there was a continual relationship between the nerve supply and the muscular homology throughout the entire animal series; but the nerve supply could not be looked upon as an infallible guide.

ACTION BY A MEDICAL PRACTITIONER.

Law is proverbially uncertain, and an example is now at hand. In the Common Pleas Division last week, the case of O'Callaghan *v.* Vigors came before the Lord Chief Justice and two other judges. The plaintiff, who is surgeon to the County Carlow Infirmary, brought an action against Mr. Vigors for alleged libel, in reference to the treatment of a boy who had been under Dr. O'Callaghan's care. The case was tried last June in Dublin, when damages to the extent of £500 were awarded to the plaintiff. A conditional order having been obtained to set that finding aside the matter was now argued, and, as a result, the verdict has been set aside. One of the judges was for upholding the verdict and two were against it.

TYPHOID FEVER IN DUBLIN.

Typhoid fever for some time past has been unusually prevalent in this city, and a good many deaths have taken place, chiefly among the well-to-do classes. Cases of fever for the past few years have occurred in some of the Dublin Barracks, more especially the Royal Barracks, and it was believed that they were due to defective sanitation, but the authorities, including the medical officers, have denied that there were any grounds for this assertion. Whether the alleged contamination of the Vartry water has anything to do with the matter it is impossible to say; at all events, the fact remains that enteric fever prevails to a considerable extent in Dublin at present.

An election for a coroner for the Tipperary district took place last week. There were six candidates, five being medical men, and one a solicitor, Dr. Moloney, who was the successful candidate, the voting being as follows:—Moloney, 518; Morrissy, 437; Ryan, 421; Conway, 381; Humphries, 320; Frewen, 325.

Sir George H. Porter, J.P., Surgeon in Ordinary to the Queen in Ireland, has been appointed a Deputy Lieutenant for the County of Wexford.

Mr. John P. Nowlan, for upwards of thirty years medical officer to No. 1 North City Dispensary Dublin, died this week, aged fifty-four years.

Dublin, Nov. 23rd.

BELFAST.

(From our own Correspondent.)

THE ROYAL HOSPITAL.

AT the annual meeting of the supporters of this charity, held on Nov. 15th, I learn from the reports that 2134 intern patients were treated during the year, of whom 897 were medical, the rest surgical; while in the extern department 14,750 new cases have been treated, and of these 2125 were medical, the remainder, 11,339, surgical. The average daily attendance was abont 106. The internal and external cases together numbered 16,884. Clinical instruction has been given in the wards to 159 students during the winter, and to 83 during the summer session. Turning to the finances, I find that the receipts during the year amounted to £8370 11*s.* 6*d.*, and the expenditure to £9418 19*s.* 8*d.*, leaving a deficit of £1048 8*s.* 2*d.*, but when two special items for [illegible] are deducted (for building a laundry and for

additions to the fever wards) the actual excess of expenditure is £797 12s. 10d. Special expenses have been incurred during the year owing to the lamentable and protracted riots, and owing to the terrible railway accident at Portadown. No doubt the Great Northern Railway Company will recoup the hospital in connexion with the latter matter, but it is to be regretted that the Government did not see their way to make a grant towards the special and altogether unforeseen expenses incurred in the treatment of patients injured during the riots.

THE CONSUMPTION HOSPITAL.

During the year the Consumption Hospital has been completed and opened at the Throne, and through the generosity of Mr. Forster Green and the kindly co-operation of other friends, an endowment of £5888 10s. was raised, so that eight beds are supplied for consumptive patients. Dr. Lindsay has been appointed medical attendant. Important alterations and additions have been made in connexion with the fever wards, and the place is now equipped in the most complete manner for the separate treatment of the different fevers; and further, a much-needed improvement has been made in the laundry department. Special reference was made at the meeting to the great services rendered during the past year by the medical officers, especially by those of the surgical staff, whose energies were often overtaxed during the past riots. Other matters referred to in the report were the presentation of a stained-glass window to the hospital by Dr. Whitla (one of the physicians), and a portrait of Mr. Lyons, whose services to the hospital have been so useful and so prolonged. At the meeting Mr. Lyons, D.L., was appointed President of the Hospital in the room of the late Lord Shaftesbury, and a resolution was passed that a strenuous effort should be made to wipe off the deficiency on this year's account.

ULSTER MEDICAL SOCIETY.

The opening meeting of this Society was held in the Museum on the evening of Nov. 17th, when the inaugural address was given by the President (Dr. Whitla). After having referred to the loss the Society has sustained in the deaths of Dr. Henry MacCormac, Dr. Andrews, and Dr. Purdon, Dr. Whitla proceeded to give a rapid survey of the present position and prospects of therapeutics, with a glance at its relation to some of the neighbouring departments of medical science. At the conclusion of the address a vote of thanks was passed to the President.

THE MEDICAL STUDENTS' ASSOCIATION.

The opening meeting of this young Society was held last week in the Natural Philosophy Lecture-room of Queen's College. The chair was occupied by the Rev. Dr. Porter, President of Queen's College, who delivered a very suggestive and interesting address, showing the great interest he takes in the welfare of the students. After Dr. O'Neill, Dr. Byers, and the new assistant to the Professor of Anatomy (Dr. Chambers) had spoken, a discussion arose in reference to the Medical School, &c., and a very pleasant reunion was brought to a conclusion.

DEATH OF SAMUEL M. MALCOMSON, M.D.

It is with extreme regret I have to announce the death of this talented young medical man, at his residence in Belfast, at the early age of twenty-nine. After studying at Belfast and graduating in the Queen's University in 1879, he was appointed one of the resident staff in the Union Infirmary, where he gained a wide clinical and pathological knowledge. A few years ago he began private practice in town. He was a capital microscopist, and did some very original work in connexion with the Foraminifera. He was a member of the Naturalists' Field Club, and at the meetings of that society his preparations excited great interest. He commenced a class on Microscopy, which was largely attended by the medical students. About a year ago symptoms of pulmonary consumption set in, from which he finally died. His death is much regretted by a large circle of friends, both within and outside the profession.

Belfast, Nov. 24th.

THE PHARMACEUTICAL CHEMISTS IN HAVANA.—The Pharmaceutical chemists in Havana are complaining bitterly of a new regulation of the Spanish military authorities ordering the pharmaceutical department to arrange to supply all military men and their families with medicines of all kinds at cost price.

PARIS.

(From our own Correspondent.)

MERLATTI.

WHATEVER question there may be as to the propriety of sanctioning such experiments as those now being made by Merlatti, it is useless to ignore an accomplished fact, and I have no doubt that some of your readers will be glad to learn the real facts of the case. Some five or six weeks ago, when the daily press was discussing the arrival of Succi in Paris and his proposal to renew his thirty days' fast under the surveillance of a French committee, Dr. Philip Maréchal, a contributor on scientific subjects to the *Voltaire*, was prominent in scouting the possibility of success. It appears that, in consequence of one of these articles, a number of candidates begged to be submitted to the test—a favour which was naturally declined; but one young man, an Italian (Stefano Merlatti), declared that he had fasted for lengthened periods previously, and ultimately succeeded in inducing Dr. Maréchal to form a committee for the purpose of conducting another experiment. Dr. Maréchal made known his acquiescence in a note to the *Voltaire*, in which he anticipated that the attempt would be abandoned at the expiration of a fortnight. He also gave the names of the members of the committee, with whom lies the responsibility of the experiment, and who vouch for its genuineness. These are Dr. Audhoui, physician to the hospitals, M. Victor Meunier, Dr. Dutrieux-Bey, Dr. E. Monin, Dr. de Montplaisir, Dr. P. Combe, and Dr. P. Collin. Merlatti is said to have been in robust health without any physiological peculiarity; the heart normal; somewhat thin, and weighing sixty-one kilogrammes. By way of preface to the proposed fifty days' abstinence, Merlatti partook of a farewell meal, consisting of the whole of a fat goose, *including the bones*, a couple of pounds of roast beef, enough vegetables for two ordinary men, and dessert comprising, amongst other dainties, walnuts, which he ate *with their shells*. I thought of these details this afternoon when Merlatti, in whose mind the delicacy was no doubt associated with my nationality, confided to me his intention of making up for lost time, later on, with plum-pudding. Since this meal, just four weeks ago, Merlatti has lived entirely upon pure filtered water, and has been subjected to the strictest surveillance, for the effectiveness of which the committee vouch. His weight, temperature, pulse, and respiration have been noted daily, as well as his strength, spirometric capacity, and excretion of urea. I had not seen him until four days ago, when, in consequence of a report that his prostration and emaciation were extreme, I asked to be allowed to take some sphygmographic tracings, and received a courteous permission from the committee to examine their subject. Upon my first visit I was struck with his satisfactory condition, quite the reverse of what would have been anticipated. The arms, bared for the application of the sphygmograph, were well nourished, and I remarked that there was no particular prominence of the malar bones—a remark which did not, however, meet with the concurrence of those present. The only sign of fatigue was dilatation of the pupils. Merlatti was calm and cheerful, and exhibited no signs of restlessness or agitation. Had not the genuineness of the fact been endorsed by the committee, and confirmed to a great extent by the quantitative analysis of the urine, I should have considered the whole affair an imposture. The tracing on this occasion is one of low arterial tension, with a deep aortic notch, preceded by a rapid fall from the apex. I took another tracing this afternoon, which, together with the information afforded by auscultation, seems to give a very serious indication of the danger of pushing the experiment much further. The tracing of the pulse of the twenty-fourth day shows about seventy-six beats to the minute, low tension, but a well-filled artery; that of the twenty-eighth day, eleven beats only in one-sixth of a minute, making sixty-six per minute. The heart, which was normal a month ago, now gives a reduplication of the second sound, which, however much the subject of discussion in its causation, I take to be in this case from want of ventricular harmony, due to defective innervation. The line of descent comes down gradually during the whole of the systole, which is evidently taking place under high cardiac pressure, and ends with a diastolic plateau indicating an empty condition of [illegible] Merlatti's appearance is also much [illegible] spirits, the loss of flesh

is very marked since my first visit, and the features have become haggard. The excretion of urea has fallen to 8 grammes per day, being an average of 3 grammes to the litre; and the loss of weight amounts to just 22 lb.

Paris, Nov. 24th.

PUBLIC HEALTH DIPLOMAS.

AT present there seems great difficulty in securing similarity in the nomenclature of qualifications and the subject qualified in, and in arranging for some distinctive conventional abbreviation by which those qualified specially in Sanitary Science or Public Health may be known, now that such diplomas are registrable. The following table shows at a glance the great diversity which obtains:—

University or medical corporation.	Designation of qualification.	Designation of subject, &c.
Royal College of Physicians, London	Certificate	Hygiene
Royal College of Physicians, Edinburgh	Certificate	Public Health
King and Queen's College of Physicians, Ireland	Certificate	Sanitary Science
Faculty of Physicians and Surgeons, Glasgow	Certificate	Public Health
University of Oxford	Certificate	Public Health
University of Cambridge	Certificate	Sanitary Science
University of Durham	Licence	Sanitary Science
University of London	Certificate	Public Health
University of Edinburgh	Bachelor and Doctor of Science	Public Health
University of Glasgow	Qualification	Public Health
University of Dublin	Diploma	State Medicine
Royal University of Ireland	Diploma	Sanitary Science

Of the twelve diploma-giving bodies, seven give certificates, two diplomas, one a degree, one a licence, and one a qualification.

Obituary.

SIR JOHN HUMPHREYS, J.P., D.L.

BY the death of Sir John Humphreys, which occurred on Saturday last, the Coronership for the Eastern Division of Middlesex is rendered vacant, and the county has sustained the loss of one who for nearly twenty-eight years discharged the duties of his responsible office with marked ability, dignity, and circumspection. On the death of the late Mr. Serjeant Payne, Sir John was elected to the presidency of the Coroners' Society of England and Wales, and he was consulted by the late Government on the Bill dealing with the office and duties of coroner brought in by them. In our opinion, a medical man rather than a lawyer is better adapted for the duties of a coroner, but in Sir John Humphreys we recognise a rare exception. His eminently judicial mind, coupled with an excellent knowledge of surgery (a fact not generally known) peculiarly qualified him for the post. To these must be added his strong practical sense and his untiring industry. Besides the duties of his office as coroner, Sir John held the post of chief clerk to the Commissioners of Income Tax, and for many years took an active interest in liberal politics. Many members of Parliament obtained their seats in the House from the organising powers and energy he displayed in the conduct of elections. He was more than once invited to seek Parliamentary honours himself, but he always preferred assisting others to obtain them. He usually enjoyed vigorous health, but in the spring of 1885 he had a severe attack of pleurisy and pneumonia. At one time his life was despaired of, but he pulled through after a long and trying illness. Last summer he resumed his duties, but some weeks before his death his former complaint returned, and he was tapped in the chest at Braemar, where he was staying for the benefit of his health. Soon after he returned to 20, Devonshire-street, his town residence, where he remained, under the care of Dr. F. Spurgin, until his death. He was in his seventy-third year, and leaves his widow, a son, and a daughter to mourn their loss. He was a J.P. and D.L. of the Tower Hamlets, and in the autumn of 1881 received from Her Majesty [illegible] the Coronation.

THE ELECTION OF DIRECT REPRESENTATIVES.

OWING to the unfortunate delay in counting the votes and holding the meetings of the Branch Councils, we are at present unable to give our readers definite information as to the state of the poll either in England or Ireland. That of Scotland has been known for two days. The aggregate vote is understood to be a large one, and to reach nearly 13,000.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Nov. 18th:—

England, Guy Fuller Ashbridge, M.R.C.S., Winchester.
Lewis, David Thomas, Brunswick House, Stoke Newington-road.
Walsh, Robert Wm., M.R.C.S., The Priory, Lincoln.
Warlters, Walter Scott, M.R.C.S., Chepstow Villas, Bayswater.

A RATHER serious outbreak of typhus fever is reported to be raging in Leeds.

ON the 21st inst. a demonstration was held at Trowbridge in aid of the local cottage hospital.

WOMEN DOCTORS.—The Orel district authority has decided that it is impossible to allow female practitioners to discharge the functions of district surgeons.

A FAMILY of four people are reported to have been poisoned at West Bromwich through eating tinned salmon. One of the cases has terminated fatally.

AT a meeting of the Society of Arts held on the 24th inst., Mr. William Anderson, M.I.C.E., read a paper on "The Purification of Water by Agitation with Iron and by Sand Filtration."

The Hospital for the current week contains an article by Lord Salisbury, in which he gives his views of the general depression of the times and the public duty involved in the adequate support of the hospitals.

VACCINATION GRANT.—Mr. John Winnall George, public vaccinator of the Upton and Leigh districts, Worcestershire, has been awarded the Government grant for efficient vaccination (third time).

A SALE of work in aid of the St. Mary's Hospital extension fund was opened at Manchester on the 19th inst. The bazaar remained open until the evening of the 20th, and was highly successful.

AT the concluding meeting of the Leeds Musical Festival Committee, on the 19th inst., it was reported that the total receipts amounted to £10,500, and the expenditure to about £8000. The balance will be distributed amongst the medical charities in the borough.

MEASLES.—In consequence of the great prevalence of measles at Tadcaster, Yorks, the School Board at a special meeting on the 19th inst. determined to close the schools for a period of five weeks. At Lichfield also the disease is said to be extensively prevalent.

PRESENTATION.—On the 18th inst., Mr. Thomas Odell, who has recently resigned his post as one of the honorary medical officers of the General Infirmary at Hertford, after holding that office for the long period of twenty-four years, was presented with a silver salver and a purse of fifty guineas.

LEEDS MEDICAL CHARITIES.—The second of a series of ward meetings in aid of the movement for increasing the contributions of the working classes to the Leeds medical charities by means of regular weekly or monthly subscriptions was held on the 16th inst. A resolution was adopted approving of the formation of the Workpeople's Committee, and pledging the meeting to support the

SCARLATINA IN ODESSA.—The number of patients suffering from scarlatina who have asked for admission into the town hospital of Odessa is so large that a special building has had to be erected for their reception.

PUNISHMENT OF A RUSSIAN QUACK.—A quack in Moscow, who was formerly a soldier, recently gave a syphilitic patient a mixture which caused vomiting and acute gastritis, which was ultimately followed by death. The quack was brought before the local court of justice, which sentenced him to two months' imprisonment and ecclesiastical penance.

FATAL MISTAKE IN A POLICE LAZARET.—In a lazaret attached to a Moscow police-station an attendant recently administered by mistake a tablespoonful of a strong solution of carbolic acid to four patients, who at once complained of a burning sensation in the throat, and soon presented all the symptoms of carbolic acid poisoning. The surgeon managed to save all except one of the victims, who died the next day.

AFTER-CARE ASSOCIATION FOR POOR FEMALE MENTAL CONVALESCENTS.—H.R.H. Princess Christian having graciously accepted the office of patroness, and Lord Brabazon that of president, the committee intend at once to commence active operations and open a convalescent home, for which about £1000 is required, and help most urgently needed. The secretary is Mr. H. Thornhill Roxby, Emblewood, Osbaldeston-road, London, N.

VOLUNTEER MEDICAL STAFF CORPS.—An amateur dramatic performance will be held at Toole's Theatre on Friday, December 17th, at 2 P.M., in behalf of the fund for raising new headquarters for the corps. The performance is under the immediate patronage of the honorary commandant, the surgeon-commandant, and officers of the corps. The plays to be performed are "The Wonderful Woman" and "Checkmate," the parts to be taken by members of the corps.

SEWER REFUSE AS MORTAR.—The inspector of nuisances of the parish of Bermondsey recently reported to the vestry that sediment taken from the public sewers was being used as mortar in the construction of houses. Owing to the offensive smell arising from the stuff, the inspector, considering it injurious to health, ordered its removal. The vestry instructed the clerk to write to the Metropolitan Board of Works upon the subject, and the Board has replied to the effect that steps have been taken to prevent a repetition of the objectionable practice.

THE STURGE PRIZE ESSAYS.—The Rev. Canon Clarke, Hon. Conrad Dillon, and Mr. J. S. Wood, who were appointed adjudicators by Mr. George Sturge to determine the three best Essays on "The Causes of the Financial Depression in the London Hospitals," have just given the following awards:—1st prize (£25), Dr. H. N. Hardy; 2nd prize (£10), Mr. B. Burford Rawlings; and 3rd prize (£5), Dr. R. Rentoul of Liverpool. There were a very large number of competitors. The successful essays will, we understand, appear in *The Philanthropist*.

Medical Appointments.

Information for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BURRELL, A. W., M.B.Lond., M.R.C.S., L.R.C.P., has been appointed House-Surgeon to the London Hospital.

DUNCAN, THOMAS, M.B., C.M.Edin., has been appointed Medical Officer for the Parish of Udny, Aberdeenshire.

EVANS, C. S., M.R.C.S., L.S.A., has been appointed Resident House-Physician to St. Thomas's Hospital.

GODFREY, A. E., L.R.C.P., M.R.C.S., has been appointed Resident Accoucheur to St. Thomas's Hospital.

HAILES, CLEMENTS, M.D., &c., Edinburgh, has been appointed Medical Officer to the Redland Branch of the Clifton Dispensary.

JONES, S. H., M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

KIDD, PERCY, M.D., F.R.C.P., has been appointed Medical Officer to the Rock Life Assurance Company, vice Frederick J. Fane, M.D., F.R.C.P., deceased.

LICHFIELD, JAMES WILLIAM, L.R.C.P.Lond., has been appointed Junior Assistant Medical Officer to the Hants County Asylum.

MONTAGUE, A. J. H., L.R.C.P., M.R.C.S., L.S.A., has been appointed Non-resident House-Physician to St. Thomas's Hospital.

MOXON, HENRY J., L.D.S., has been appointed Dental Surgeon to the Schools of the Westminster Union.

NAIRN, R., L.R.C.P., M.R.C.S., has been reappointed Ophthalmic Clinical Assistant to St. Thomas's Hospital.

NICHOL, F. R., L.R.C.P., M.R.C.S., has been reappointed House-Surgeon to St. Thomas's Hospital.

PRATT, REGINALD, M.D., M.R.C.S., L.S.A., has been appointed Assistant Surgeon to the Leicester Infirmary.

RITCHIE, E. D., M.B., B.C.Cantab., M.R.C.S., L.S.A., has been reappointed House-Surgeon to St. Thomas's Hospital.

SMYTH, H. J., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

SOLLY, E., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

STAHR, E. C., L.R.C.P., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

STAVELEY, W. H. C., L.R.C.P., M.R.C.S., has been appointed Assistant House-Physician to St. Thomas's Hospital.

TOTSUKA, K., L.R.C.P., M.R.C.S., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

WHEATON, S. W., L.R.C.P., M.R.C.S., has been appointed Resident House-Physician to St. Thomas's Hospital.

Births, Marriages, and Deaths.

BIRTHS.

ASHTON.—On the 23rd inst., at York, the wife of Brigade-Surgeon Wm. Ashton, M.B., Medical Staff, of a son.

BECKINGSALE.—On the 17th inst., at Cordova-street, Vancouver City (late Granville), British Columbia, the wife of D. Loftus Beckingsale, M.D.Ed., of a son.

DAVIDSON.—On the 19th inst., at the residence of her father, The Dingle, Sydenham-hill, the wife of D. C. Davidson, L.R.C.S., L.R.C.P.Ed., Indian Medical Service, of a daughter.

KERNOT.—On the 18th inst., at Bishnauth, First Avenue, West Brighton, Sussex, the wife of C. N. Kernot, M.D. St. And., M.R.C.S., of Calcutta, of a daughter.

TAYLOR.—On the 16th inst., at Highgate, Kendal, the wife of B. R. Archer Taylor, M.R.C.S., of a son.

TINKER.—On the 22nd inst., at Brookland House, Hyde, Cheshire, the wife of Frederick Howard Tinker, L.R.C.P., M.R.C.S., of a son.

MARRIAGES.

BOLTON—HAY.—On the 18th inst., at Nottingham, Joseph S. Bolton, M.D., M.R.C.S., of Nottingham, to Jessie, daughter of the Rev. J. Hay.

COX—ELLIS.—On the 23rd inst., at St. Matthew's, Ealing, Staff-Surgeon Henry Thompson Cox, Royal Navy, to Emma Louisa, elder daughter of Staff-Commander John H. Ellis, Royal Navy.

GREENHILL—PERMAN.—On the 20th inst., at the Cathedral, Calcutta, Edward Fowler Greenhill, M.R.C.S., L.R.C.P., to Florence Ellen, second daughter of Thomas Perman, of Stoke Newington, London.

PARSON—COLMAN.—On the 20th inst., at St. Giles'-in-the-Fields, Charles Jenner Parson, M.R.C.S., L.S.A., to Susie, third and youngest daughter of Frederick Charles Colman, of Cumberland House, Kew, Surrey.

RUDD—HARRISON.—On the 17th inst., at the Parish Church, Great Yarmouth, Charles Frederic Rudd, M.R.C.S., L.S.A., to Clara Florence, youngest daughter of the late Henry Harrison, of Great Yarmouth.

SLOMAN—PAUL.—On the 17th inst., at St. Giles' Cathedral, Edinburgh, Herbert Sloman, L.R.C.P.Lond., M.R.C.S., to Bessie, elder daughter of the late William Paul, Banker, of Glasgow.

DEATHS.

BALDING.—On the 23rd inst., at St. Alban's, Mortimer Balding, B.A., M.D.Cantab., M.R.C.S.Eng., youngest son of the late James Balding, M.R.C.S., of Barkway, Herts, aged 36.

BALFOUR.—On the 17th inst., at East Brighton-crescent, Portobello, N.B., Andrew Howden Balfour, L.R.C.S.Ed., in his 68th year.

SURRAGE.—On the 19th inst., at Saville-place, Clifton, James Surrage, M.D.Ed., M.R.C.S., late of Wincanton, Somerset, in his 75th year.

SUTTON.—On the 19th inst., at Denbigh-street, Warwick-square, S.W., John Sutton, M.R.C.S., in his 77th year.

WILME.—On the 13th inst., at Northumberland-place, Bayswater, Richard Wilme, M.D., late of Manchester.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the Journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

"ADVICE GRATIS.—MEDICAL."

UNDER the above heading our old friend, *Mr. Punch*, is wisely, as well as wittily, caricaturing "newspaper therapeutics." His "Own Fellow of the Royal College of Physicians (Chattanooga)" gives advice as follows:—

"*Sufferer.*—You will find petroleum a very good substitute for best Brittany butter, if you cannot afford the latter. Read my book, 'Dyspepsia, its Cause and Cure.' *A. S. S.*—A cold in the head is usually symptomatic of an inflammatory condition of the upper part of the air-passages. It will no doubt materially assist you to get rid of the one you have got, and which you say has lasted without intermission since 1848, to know that its scientific name is 'coryza.' This is as much information as you deserve without forwarding my fee, which, I may remind you, is far less than you would have to pay if you consulted any respectable local medical man. *W. E. G.*—1. Read 'Dyspepsia, its Cause and Cure.' 2. Of course, if you wish it, I should have no objection to meeting Sir A—— C—— in consultation. My fee would be three-and-sixpence. N.B.—Please do not write on post-cards."

W. C. (Chester).—1. We have no means at hand of ascertaining the point.—2. The title was given in the case mentioned more from social considerations than on account of length of service.

Dr. J. B. Russell (Glasgow).—The lecture was delivered at Toynbee Hall, Whitechapel, on the 17th inst., and a brief abstract of it was published in some of the London newspapers on the 15th.

Inquirer (Kensington).—The information could be obtained only by canvassing the whole profession.

MEDICAL CELEBRATION OF THE QUEEN'S JUBILEE.

To the Editor of THE LANCET.

SIR,—It is almost time that we of the medical profession should be considering in what way we may best celebrate the jubilee year of the Queen's reign. Permit me to suggest that it would be a suitable opportunity for a great and united effort on our part to place the funds of our own particular Benevolent Institution in a better state, or to raise a separate fund towards providing a school for the daughters of medical men, who, I observe, are not included in the existing arrangements. On such a memorable occasion (if the suggestion I have made should be taken up in influential and favourable quarters) I feel sure that we would all of us subscribe according to our means, and that there would be many real jubilee subscriptions of fifty guineas each.

I am, Sir, your obedient servant,

F. WILLIE REMAN, M.D.Edin.

Ramsbury, Hungerford, Berks, Nov. 23rd, 1886.

ACUTE RHEUMATISM COMPLICATED BY A BULLOUS RASH (PEMPHIGUS?).

To the Editor of THE LANCET.

SIR,—Dr. Benham's case has interested me very much, but I think it admits of more than one explanation. Thus, it may (1) be a *bonâfide* complication of acute rheumatism, as the author suggests; (2) occurring for the first time after three days' "copious perspiration," it may result from extreme functional excitement of the sweat glands; or (3) after eighteen twenty-grain doses of salicylate of soda, given at intervals of four hours, it may be merely a medicinal rash, comparable to those following the administration of iodide or bromide of potassium, of belladonna, or copaiva. The first point has been sufficiently discussed by the author, though his conclusions can scarcely be said to be proven. With regard to the second point, excessive activity of the sweat glands, with its accompanying hyperæmia, may not improbably give rise to œdema of the tissues surrounding the sweat-duct, thus mechanically occluding it and setting up what may be termed deep pseudo-vesiculation. This may make its way to the surface by abnormal channels, particularly if it be true that there is free communication between the lumen of the sweat-ducts and the periglandular lymph spaces, and thus produce vesicles of any size, from that of a pin-point to the bullæ described. The fact that on the 5th of April a "crop of large irregular blebs appeared," seemingly at about the same time as the "slight return of the rheumatism in the finger-joints of the left hand," does not disprove, but rather tends to support, this view, for with the return of the rheumatism there would be renewed activity of the sweat-glands. The breaking down of the vesicles proves nothing, for any vesicle may do that, while slow healing would result from the pathological pressure to which the parts had been subjected. Concerning the third point, the large repeated doses of salicylate of soda may account for the whole of the skin phenomena. Therapeutic idiosyncrasy may in this case have much to answer for. When a patient taking copaiva during treatment for gonorrhœa develops the typical copaiva rash, one scarcely attributes the rash to the complaint, rather do we assign the development to its true cause, and call it a medicinal accident. May we not blame the drug in Dr. Benham's case? That the phenomenon has not been previously noted counts for little. A single dose of iodide will occasionally induce all the symptoms of iodism, but how many people take repeated doses of that drug without any sign of coryza?

This solitary case, then, can scarcely be admitted as strong evidence of an "intimate connexion between E. papulatum and rheumatism." Coincidence of the rash with the rheumatic symptoms (April 5th) would be explained by (2), while alternation might readily be caused by increase or wane in the physiological influence of the drug employed. Are we justified, therefore, in adding yet another burden to the already all but interminable list of skin diseases? The sudden access of severe symptoms would easily explain the inability of the several glands to discharge the unexpectedly increased duty thrust upon them and the consequent development of all the local phenomena. Lastly, I am not acquainted with any reason why Bazin's hydroa should not occur independently during the course of acute rheumatism, and, indeed, Dr. Benham's case closely resembles (excepting the rheumatism and high temperature) the two cases of true hydroa that I have been fortunate enough to examine.

I am, Sir, faithfully yours,

Pall-mall East, S.W., Nov. 20th, 1886. ARTHUR HARRIES, M.D.

To the Editor of THE LANCET.

SIR,—On reading the paper headed as above, by Dr. Benham, in THE LANCET of the 20th inst., it occurs to me that the administration of the salicylate of soda, especially in the doses stated, may account for the development of the rash. Some years ago I had under treatment a severe case of rheumatic fever which had resisted the ordinary remedies, and as the salicylate of soda treatment was at the time coming into vogue, I prescribed the latter treatment, with the result that after several doses had been given, the patient, a stout female, was covered over with a rash, not unlike what is described in Dr. Benham's patient. There was, however, no remission of the rheumatic pain or swelling of the joints, and I had reluctantly to discontinue the remedy. There was also present much delirium, which caused me considerable anxiety. I have seen it stated in medical periodicals that this rash has been noticed in connexion with the administration of salicylate of soda in some constitutions, and I think that this point should be definitely settled.—I remain, Sir, your obedient servant,

JOHN COCHRANE, L.R.C.P.Ed., &c.,
Medical Officer of the Parish of Strath, Skye.

Broadford, Skye, Nov. 22nd, 1886.

Doubtful.—We do not see that our correspondent has any claim, and feel pretty sure that the suggested application would simply entail the unpleasantness of a refusal.

A. Z. is referred to the reply given to "Dr. Ingle" last week, page 1009.

PRACTICAL HINT ON THE PERFORMANCE OF TRACHEOTOMY.

To the Editor of THE LANCET.

SIR,—If Mr. Braddon will look at page 39 of the third edition of "Surgical Emergencies," he will find directions for the performance of the operation of tracheotomy which to all intents and purposes coincide with his suggestion.

I am, Sir, yours faithfully,

Plymouth, Nov. 20th, 1886. PAUL SWAIN.

OUTBREAK OF ANTHRAX IN CATTLE.

To the Editor of THE LANCET.

SIR,—The history given by Mr. Fraser in your issue of the 9th ult. is very interesting. It points strongly to the fact that in this disease, as in all others due to the absorption into the blood of infective material, that fluid is to a greater or less extent deprived of its fibrin-forming power. During my term of office as a civilian surgeon attached to the Army Medical Department in South Africa in 1879 I had many opportunities of observing the course of that terrible scourge called "horse sickness," and I dissected many horses and mules which had died of it. In this disease the blood becomes so fluid that the liquor sanguinis passes into the air-cells and bronchi, and the animal dies with the frothed-up serum running out of its nostrils—drowned by its own blood. On dissection the pleural cavities, pericardium, and bronchi are filled with serum, whilst the parenchyma of the lungs and the subcutaneous tissues are infiltrated with the same fluid. In mules the subcutaneous tissue is more affected than in horses, giving rise to a thick-headed appearance, called "dikkop" by the Dutch—one of the names by which the disease is known. There are no signs of inflammatory action anywhere. There is no looseness of the bowels. In the mesenteric glands I found numbers of small worms, which must, I think, have passed from the intestines in the embryo form. It is to their presence that I attribute the development of the disease. Horses are believed to take it more readily when allowed to graze whilst the grass is wet with dew. In malignant scarlet fever, blue measles, hæmorrhagic small-pox, &c., we also see the development of extreme fluidity of the blood, giving indications to us for treatment by hæmatinics, such as the strong preparations of iron. The symptoms in the case of Henry P——, recorded by Mr. Fraser, point, in my opinion, not to pneumonia, but simply to extreme fluidity of the blood, caused by the poison of anthrax, and giving rise to passive congestion of the lungs from the effusion of bloody serum into the air-cells. The symptoms were, of course, aggravated by the well-marked heart disease. Those cases reported as being under the care of Mr. McKenzie are interesting, in that they show the value of absolute phenol as a local application. With full doses of iron internally much more may, I think, be done in the treatment of such diseases. On this principle I have treated cases of malignant scarlet fever and measles with large doses of the perchloride every hour, and have seen rapid recovery follow in cases which seemed hopeless. In typhoid and puerperal fevers also I have found iron to be the best of all medicines. Hence my advocacy of the "iron treatment" of all diseases due to infective absorption from any source whatsoever. I am, Sir, your obedient servant,

Clayton le-Moors, Oct. 14th, 1886. C. R. ILLINGWORTH, M.D.

Enquirer (Cheltenham).—1. It is better to follow the custom of the place.—2. Yes.

Lurie.—With much respect.

CONSULTANTS AND GENERAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—Just lately the parents of a child whom I have been attending wished for a second opinion, and I suggested a London consultant of good standing, and wrote to him detailing the case, treatment, &c., and an appointment was made through me. After seeing the case, the consultant advised the parents and gave a prescription for medicine suggested; and then wrote to me stating what he thought of the case, saying that he had given the parents his prescription. The net result of which is that through recommending the patient to him I lose all further benefit of the case, as the medicine is obtained at the druggist's, and my attendance is no longer required (at any rate for the present). I shall be rather chary of consultants (so-called) for the future, and would be glad to know if such be the usual practice with consultants. I was under the impression that the consultant's opinion and suggestions as to treatment, medicine, &c., should be given *only* to the medical man in charge of the case, and at whose suggestion the particular consultant is usually chosen; as, if not, the poor "G. P." commits a suicidal act by ever wanting another opinion. Also, is it allowable to the consultant to see a patient, who has been sent by the ordinary medical attendant the first time, further times in the progress of the same case, without the ordinary medical attendant's sanction?

I am, Sir, yours faithfully,

Nov. 17th, 1886. FAIRPLAY.

*** We agree with "Fairplay" that the consultant in the above case should have communicated with the general practitioner, and suggested to him the medicine to be prescribed. There would be very much more beneficial intercourse between consultants and family practitioners if the reference to them took the form of a consultation, instead of having the appearance of superseding the ordinary adviser. This involves a little more trouble, we admit, to men whose leisure is often very limited; but the curious thing is that the busiest men are often the most exemplary in this matter.—ED. L.

W. B.—The matters to which our correspondent refers are purely legal, and he should be advised by his solicitor. As to the advertisement, it should be sent to the body from which the gentleman obtained qualification.

B.A. Cantab.—We regret we are not in a position to answer the question.

CORXISTENCE OF MEASLES AND SCARLATINA IN THE SYSTEM.

To the Editor of THE LANCET.

SIR,—The following will be of interest as showing how two diseases may be developing at the same time. Early this year I was requested by one of my patients to call and see two of the family, female twins aged four years. Upon examination, I found No. 1 child suffering from a well-developed attack of measles, accompanied by severe bronchitis, throat and tonsils highly congested, but no diphtheritic or ulcerative patches. No. 2 child had a well-marked eruptive scarlatina rash covering the whole body, and a decided diphtheritic throat. By the fourth day the measles rash had disappeared from No. 1 and an eruptive scarlatina rash was appearing, the throat assuming a diphtheritic appearance. During the next three days the rash fully developed with serious throat complications. No. 2 child during this time was suffering from a severe form of anginosa scarlatina, but at the end of five days the scarlatinal rash had disappeared, throat symptoms considerably improved, and the measles rash at once coming out, but not so well marked as No. 1, and without chest complications. Both children desquamated freely, and at the end of six weeks had made a good recovery. Although I am constantly amongst these two diseases, I cannot call to mind any case where the evidence has been so decided that the two diseases may coexist so closely in the same system. Neither could I obtain any proof that the children had been exposed to either of the infectious poisons, as no other cases were known to be in the neighbourhood.

I am, Sir, yours faithfully,

Everton, Liverpool, Nov. 1886. CHAS. J. R. LAWDAY.

Bolton.—Unless the friends were determined in wishing B to see the case over a length of time, and to operate, he was to blame. Where there is any chance of removing a mammary tumour by medical means surgical ones should be postponed, and it is legitimate to temporise. But B could surely have secured the necessary delay and trial of remedies by communication with A, and certainly should not have taken the case without such communication.

Mr. W. A. W. Jameson and *others.*—The publishers of "Twenty Doctors" are Messrs. Hamilton, Adams, & Co.

UNQUALIFIED ASSISTANTS.

To the Editor of THE LANCET.

SIR,—I see by the report of the Medical Council that it is desired by some that steps should be taken to stop the use of unqualified assistants. Before doing so, I would like them to consider the effect of suddenly stopping a long-established custom. Many of these men have acted as assistants the best part of their lives, and by natural aptitude and study have made themselves safe and efficient advisers. They are also many of them married and support themselves and families creditably. What are such men to do? No doubt many unqualified men are totally unfit for their posts, but can we say that all qualified men are fit to be trusted? In consequence of pupilage being abolished, it is now almost impossible to get a man who is just qualified who is fit to turn into a private practice; he knows nothing of how to gain and retain the confidence of his patients, and his treatment is theoretical and often impracticable. If the Council determine to abolish unqualified assistants, let them give due notice of their intentions, allow all men who can produce evidence of a certain standard of experience to be registered as unqualified assistants, register no one after a certain date, and subject anyone who uses a non-registered unqualified assistant to a penalty. In this manner this class would be done away with without hardship or injustice, as a man entering the study of medicine would know that he must qualify if he wants to live by it.—I am, Sir, yours truly,

November 23rd, 1886. M.R.C.S.

Mr. C. J. Bond (Leicester).—Dr. Shershevski does not seem to be acquainted with our correspondent's paper on the influence of the body on the position of the heart. The address of the editor of the *Vrach*, who we believe understands English, is Professor Manassein, Simbirskaja, 12, St. Petersburg; and that of Dr. Shershevski—or "Scherschewskij," as generally transliterated—is given in the Directory as Galeerenstr., 24, St. Petersburg.

Mr. Alfred H. Whittell.—A paper was read at the Academy of Medicine of Ireland in February of last year by Dr. Walter Smith (see THE LANCET of June 6th, 1885), in the discussion of which one or two speakers expressed their belief in the infectiousness of pneumonia.

A. B.—Such a charge would be undignified in a Fellow of a College of Surgeons, but would not necessarily lead to the withdrawal of his diploma.

CRACKED OR FISSURED TONGUE.

To the Editor of THE LANCET.

SIR,—I have a case that has resisted every form of treatment. The patient, with the exception of occasional attacks of nervous depression, is in good health. There are no stomach or liver troubles to speak of. The tongue is clean, but deeply fissured. Solution of perchloride of iron painted well into the cracks appears to give the most relief. I shall be obliged if any brother practitioner who has been successful in a similar case will give me a hint as to further treatment.

I am, Sir, yours faithfully,

Nov. 20th, 1886. A YOUNG PRACTITIONER.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Chauncy Puzey, Manchester; Dr. Kendal Franks, Dublin; Mr. J. E. Erichsen, London; Dr. Poore, London; Dr. Fairbank, Doncaster; Mr. Jordan Lloyd, Birmingham; Mr. Bastes, London; Mr. Lawrence, Tunbridge Wells; Mr. J. Cochrane, Broadfield; Dr. Nicholson; Dr. Wilkie Burnham, Hungerford; Mr. H. J. Bailey, Blackheath; Dr. Dyce Duckworth, London; Dr. Handford, Nottingham; Mr. W. H. Day; Miss Hompes; Herr Vetlesen, Hamar; Mr. Fripp, London; Dr. J. W. Murray, Manchester; Mr. L. G. Smith, Tottenham; Mr. Hutchings, Baltimore; Dr. O'Neill, Belfast; Mr. Berry, Wigan; Dr. R. Park, Glasgow; Mr. Everitt, London; Dr. Oldham, Manchester; Lady John Manners, London; Dr. Swaby Smith, London; Mr. Heydon, Ben Rhydding; Mr. Wigan, Manchester; Dr. James, Winslow; Mr. Rose, London; Mr. Paul Swain, Plymouth; Dr. Harries, London; Mr. J. Rothschild, Paris; Dr. Blakeney, Brisbane; Messrs. Burroughs and Wellcome, London; Dr. Goodridge, Bath; Surgeon-Major Dobson, Southampton; Mr. Hardman, Birmingham; Dr. Lacerdo, Rio de Janeiro; Mr. Lawday, Everton; Mr. Calvert, Gothenburg; Mr. W. Medical Diary for the ensuing Week.

Monday, November 29.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
SOCIETY OF ARTS.—8 P.M. Mr. Lewis Foreman Day: The Principle and Practice of Ornamental Design (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Mr. H. Allingham: Lateral Displacement of Patella in Genu Valgum, with Congenital Malformation.—Mr. Edmund Owen: Children after Knee-joint Abscess.—Dr. Stephen Mackenzie: Paralysis of Extensors of one Forearm.—Mr. Bruce Clarke: Case of very obstinate Cystitis treated by Constant Current; and other cases.

Tuesday, November 30.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, December 1.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Mondays and Thursdays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
SOCIETY OF ARTS.—8 P.M. Adjourned Discussion on Dr. C. Meymott Tidy's paper on Sewage Disposal.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Mr. Doran and others. Dr. Dakin: Mercurialism in Lying-in Women.—Dr. Pedley: Midwifery among the Burmese.—Dr. Gibbons: Case of Galactorrhœa.

Thursday, December 2.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, December 3.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Pathological Specimens by Mr. H. Percy Dunn. Dr. Savill: Ichthyosis Sebacea, Melanoderma, Tubercular Syphilide.—Mr. Edwards: A case of Excision of the Rectum.—Mr. Whitmore: Stricture of the Rectum, with cases.—Dr. Venn: A case of Inversion of the Uterus during Parturition treated as a Polypus and Ligatured.—Mr. H. A. Reeves: Cases, with Remarks, in Gynæcological and Orthopædic Surgery.

Saturday, December 4.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months £0 16 3
TO CHINA AND INDIA ..... One Year 1 16 10
TO THE CONTINENT, COLONIES, AND UNITED STATES ..... Ditto 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

MAHARAJAH'S LIBRARY COOCH BEHAR 27 JUL 1886

The Bowman Lecture

ON THE PARASITICAL DISEASES OF THE EYE.

Delivered at a Meeting of the Ophthalmological Society,

BY WILHELM VON ZEHENDER,

PROFESSOR AT ROSTOCK IN MECKLENBURGH.

MR. PRESIDENT AND GENTLEMEN,—The invitation which I received last year from the Council of your Ophthalmological Society was, I must say, a very welcome one. I value very highly the great honour which this invitation brings with it, the more so as this lecture has been instituted with the design of gratefully commemorating the services which Sir William Bowman has rendered to science. I am fully conscious of the honour of being allowed to speak in commemoration of a man so greatly esteemed all over the Continent, and especially in my own country, because of his pre-eminent scientific position. But, having in the first moment cheerfully and decidedly consented to accept the honour conferred upon me, I afterwards felt the whole weight of my responsibility, and began to fear that I should not be able to discharge the duties which I had undertaken. It is a well-known fact that in treating of difficult matters it is not always easy to find the right words and the proper expressions, speaking even in the mother tongue; and I venture to speak before you in a language, not quite different from the German in its earliest origin, to be sure, but very different in its later development. I beg to apologise for all incorrectness of speech and deficiency of elegance; indeed, I feel sure you will overlook them.

The aim of my lecture will be to lay before you an account of the parasitical diseases of the eye—diseases very little known in earlier times, but now more and more occupying the attention of the scientific world.

The late Dr. Mackenzie, in his "Practical Treatise of the Diseases of the Eye," had only one short chapter treating of the entozoa of the organ of vision. At the present day, in consequence of the investigations of modern science, this chapter ought to be greatly enlarged. The entozoa of the human eye, mentioned in the fourth edition of that treatise, which was at that time the most valuable and the most complete work on ophthalmology, are almost all visible with the naked eye—namely, (1) filaria, (2) monostoma and distoma oculi humani, (3) echinococcus hominis, and (4) cysticercus cellulosæ. Let us see what is known at the present time of these species of entozoa.

Von Nordmann may be looked upon as the first observer of the natural history of minute living creatures in the eye. He examined an immense number of eyes of fishes, amphibians, birds, and mammals, and found therein several specimens of different entozoa. Examining the human eye, he and Gescheidt and von Ammon found in its crystalline lens also several parasites. In the extracted lenses of an old man von Nordmann found two specimens of a filiform worm, and a similar one in the cataractous lenses of an old woman. As it was impossible to give an accurate description, he named it filaria oculi humani. In another lens of an old woman he found eight specimens of monostoma, which showed some slight motion after being put in lukewarm water. Gescheidt and von Ammon also found in the cataractous lens of an old man three extraordinarily slender worms, which they closely described and judged to be the same filaria seen by von Nordmann. In a child of five months, which died of atrophia meseraica, they found between the opaque crystalline lens and its capsule four specimens of distoma oculi humani, of which they gave a detailed description. It is to be presumed that this distoma might have been an incompletely developed specimen of distoma hepatis (Leuckart). Von Nordmann as well as Gescheidt were, in the branch of helminthology, very eminent investigators and strictly truthful in their accounts. There can be no doubt that what they saw in the human eye and what they described was really that which they deemed it to be. But it is most astonishing that ever since neither monostoma nor distoma has been found in cataractous lenses, though the microscopes of to-day are much more powerful than those of fifty years ago, and though a very great number of cataractous lenses have been very closely examined.

These observations belong, therefore, to what I may call a traditionary period of the history of parasitical diseases. Nearly the same may be said of the filaria in the human crystalline lens; whereas filaria in other parts of the eye, especially under the conjunctiva, according to Guyot, is a very common disease among the negroes of Congo. This worm seems to live only in the west of Africa, in Guinea, on which account it has the name Guinea worm; but a certain number of zoologists do not think it to be quite the same as the filaria medinensis. It has, therefore, been called filaria loa, the word loa being the name of the worm in the language of the inhabitants of Congo. It is, as far as I know, only observed in the eyes of negroes;[1] and it is said that no case has been recorded in America since slavery has been abolished.[2]

Echinococcus in any part of the human body is, except in Iceland, a very rare disease. Mackenzie refers to two cases of echinococcus in the orbit, but there have been published about forty. Echinococcus has never been found in other parts of the eye except in the orbit. It causes, to be sure, more or less protrusion of the eyeball; but it does not impair the sight in any other way, and may be easily removed by operation.

Cysticercus.—Mackenzie quotes only the few cases of cysticercus cellulosæ known at the time of the edition of his book. The fourth and last edition was published in the year 1854, a few years after the discovery of the ophthalmoscope in the year 1851, and I might have said "the invention of the ophthalmoscope," but Helmholtz himself has repeatedly said that it was much more a discovery than an invention, and so I cannot but use the same expression. The discovery of the ophthalmoscope signalises the beginning of quite a new period of our special science. The internal diseases of the eye were up to that time, we may say, quite unknown. The ophthalmoscope enlightened the darkness in which internal diseases of the eye were hidden, and, respecting the entozoa of the eye, showed that the cysticercus cellulosæ does not only reside under the conjunctiva, or in the anterior chamber, or in any other part visible with the naked eye, but even in the retina and in the vitreous body, where it cannot be seen otherwise than with the aid of the ophthalmoscope; in fact, it chooses its domicile more often in these parts than anywhere else in the organ of vision.

It is very remarkable that the cysticercus has been seen at Berlin, and in some other places in the north of Germany, in a much larger proportion of cases than elsewhere. Von Graefe of Berlin was the first to observe a cysticercus with the ophthalmoscope in the internal parts of the eye, and was the first to extract it by an operation. He had already seen a considerable number of cysticerci before the first was seen at Vienna in the autumn of 1865. This curious fact is difficult to explain. At first one could deem it probable that the use of the instrument was better understood at Berlin than at Vienna, because it was in use at Berlin almost six months or more before it was known at Vienna. But its practice was very quickly acquired, and I need not say that Eduard Jaeger of Vienna was one of the most accurate observers with this instrument, and was the first to publish pictures of the fundus oculi of an admirable and unsurpassed exactness. It is necessary to look for another explanation. Since the experimental investigations of Küchenmeister and Leuckart, it has been well known that there are two different species of tapeworm residing in the digestive tube of the human body—the one with a crown of hooks round its head, the other without it. The first stage of these tapeworms, the cysticercus, exists likewise in two different forms—the one with hooks, the other without them. These crowned tapeworms in their first stage—the cysticercus—live especially in pigs, sometimes in an exceedingly great number, and in some other animals, and also in the human body. The cysticercus without hooks lives in the body of cattle, but never in the body of pigs. This fact has been sufficiently proved by feeding experiments. It is worth notifying that this cysticercus without hooks, living

[1] Leuckart: Die Parasiten des Menschen und die von ihnen herrührenden Krankheiten, 2 Aufs, Bd. ii., p. 620. Leipzig, 1886.

[2] Blanchard: Le Vie[illegible] Conjonctive. Le Progrès Méd., Nos. [illegible] 1886, p. [illegible]

in cattle, has never been found in the human body, neither in the eye nor elsewhere. It seems to be nearly certain that pork is consumed to a much larger extent in the northern than in the southern countries, and that the tapeworm with hooks is much more common in the north than in the south; the consequences of this will be that the cysticercus (with hooks) must also be much more frequent in northern than in southern countries.

But the more one studies this question the more one finds that both tapeworms, the tænia solium and the tænia mediocanellata, exists in a nearly equal proportion everywhere, and therefore the before-mentioned question is far from being satisfactorily answered. Let me quote only a few figures to prove what I have just said.

The late A. von Graefe of Berlin found one cysticercus, visible with the ophthalmoscope, in the internal parts of the eye among about 1000 patients; his cousin, Alfred Graefe of Halle, found them in about the same proportion; whereas Dr. Berlin of Stuttgart found one cysticercus among 40,000 patients; Dr. Hansen-Grut of Copenhagen, only one cysticercus among 70,000 patients; Dr. von Wecker of Paris, only one cysticercus among 60,000 patients; and Dr. Mauthner of Vienna, not one among 30,000 patients. The first and only intraocular cysticercus in Belgium was seen last year (1885). This is, indeed, a very remarkable disproportion, well worthy of being more closely investigated. Another equally remarkable fact is, that cysticercus in the internal eye is not nearly so rare as in any other part of the eye. The late A. von Graefe of Berlin only once saw a cysticercus in the crystalline lens (this being the only time that one has ever observed it in this structure), once in the orbit, three times in the anterior chamber, five times under the conjunctiva, in contradistinction to more than eighty times in the retina and in the vitreous body. Similar observations have been made by Alfred Graefe, the professor in Halle, who in his large practice sees four or five cases of intraocular cysticercus annually, and he saw only one in the anterior chamber during a period of eight years.

The brief history of cysticercus in the human body is this: Eggs of the tapeworm enter in one or other way into the human stomach. The thin covering of these eggs is dissolved by digestive action, and the living little cysticercus appears. To be sure, it has not yet been really observed, but it hardly seems possible that there could be any other means for it to reach the eye than that this minute animal passes through the wall of a bloodvessel, entering thus into the circulatory system. Carried along with the blood it may be stopped somewhere—for instance, in the choroid,—and then it creeps out, like a white blood corpuscle in a case of inflammation. Its behaviour in this place is different. It seems that the worm has a tendency to get into the vitreous body, and this action is performed with more or less impetuosity. If seated in the choroid, or under the retina, the moving of the worm gives rise to a large detachment of the retina, and sometimes one has observed that it really creeps through the retina into the vitreous. This process cannot be performed without causing the patient great discomfort. It often excites a vehement inflammation with unsupportable pain, and produces dense opacities in the vitreous, so that the minute animal can hardly be distinguished with the ophthalmoscope. If seated in the retina the little worm does not do so much harm, and generally gets more easily into the vitreous, without exciting such disagreeable sensations. Then, the vitreous remaining clear, it can be perfectly well seen with the ophthalmoscope. In a few cases one could distinctly see the crown of hooks and the movements of the animal. According to the difference in the behaviour of intraocular cysticerci, different modes of treatment are required. If the cysticercus is very unsteady and rambling, it will be necessary to perform enucleation of the eyeball directly; if it behaves quietly, and if the patient does not suffer much pain, it may be allowed to remain for a time. But, so far as we know of this very rare disease, periods of quietness and periods of restlessness are constantly alternating; and, finally, the eyeball shrinks, and sight will almost always be entirely lost. That is the reason why some operators do not think it advisable to wait at all, but to perform the operation in any case in which the presence of a cysticercus is well established. This being so, it will be the best plan to operate as early as possible when there are no inflammatory symptoms.

Instead of enucleation, one has successfully tried to extract the little animal from the eyeball. This was first performed, as I have already [illegible] He first made a large iridectomy, and afterwards extracted the worm with cannula forceps through a scleral wound made about two lines behind the corneo-scleral margin. Many other oculists have since that time successfully, as well as unsuccessfully, tried to do the same by more or less similar operations. What has been done in this way by Alfred Graefe of Halle is of much interest. No oculist has performed an equally large number of operations for cysticercus. In his last publication[3] on this subject he refers to forty-five eyes afflicted with intraocular cysticercus, operated upon by him in the eight years 1877–1885. The immediate result of these forty-five operations was completely satisfactory. In thirty cases the parasite was caught and extracted, in only one of which an unusually profuse loss of vitreous followed. In fifteen unsuccessful operations, the want of success in extracting the worm was due to dense opacities of the vitreous not allowing an exact determination of its seat, or to an unsteadiness of movement, the animal being in the middle of the vitreous and floating about in all directions. The best chance for a successful extraction is when the worm is steadily seated between the retina and choroid. Twenty-four out of the successful cases Albrecht von Graefe had the opportunity of seeing again some time afterwards. In almost all these twenty-four patients, pain and other inflammatory symptoms had entirely subsided, and the eyeball had preserved its natural form, though in some cases it was weaker than normal. The sight of the patients had increased, and in one or two of them to a considerable degree. In the fifteen cases in which it was impossible to dislodge the animal, it afterwards appeared necessary to remove the whole eyeball or the anterior part of it, an operation which is obliged to be performed when pain and other inflammatory symptoms arise. These are the results of forty-five operations performed by Professor Alfred Graefe of Halle. Few of our special *confrères* have had the opportunity of performing this operation, and only a very small number of these have performed it more than once.

From the rarity of a cysticercus residing in the interior of the eye, this disease is, in a practical sense, of no great importance, but scientifically it is highly interesting. The course of life of any living parasite in the living human body cannot be studied with less trouble and with greater exactness than that of a cysticercus living in the eye. These are almost all the parasites of the organ of vision visible with the naked eye. But there is another series of microscopical parasites, belonging to the vegetable kingdom, practically of much greater importance. Of these we have now to treat.

These micro-organisms are the lowest forms of life we know, but by no means the most indifferent for our bodily welfare. They are such small objects that it is impossible to see them unless we use the strongest magnifying power of microscopes of the very best construction, but by their enormous multitude and power of propagation they can nevertheless do us very great harm. Pasteur has demonstrated that the air owes its property of decomposing organic substances to minute particles suspended in it, which are the germs of various low forms of life, long since revealed by the microscope, but not previously shown to be the essential cause of putrescence and decomposition of organic substances. This fact was primarily only a theoretical one, but Sir Joseph Lister was the practical man who succeeded in making the knowledge of this useful for the benefit of mankind, in giving the impulse to scientific studies, which originated thoroughly new ideas of diseases and of the means of curing them. You know better than I possibly can tell you the great merits of Sir Joseph Lister with respect to his antiseptic method; I wish only to mention that he, bearing in mind that all the mischief in healing wounds arises from the vitality of these atmospheric particles, and directing his attention especially to the subject of suppuration, found carbolic acid well adapted for the treatment of open wounds. Some years passed away before the profession began to trust in these new ideas, and I remember perfectly well the first trial made with a great deal of incredulity at Rostock, and the general astonishment in observing what a remarkable retardation of suppuration was the result of this treatment. Ophthalmology, always attentively looking round for some possible advancement, did not wait very long in applying the principles of this

[3] Albrecht von Graefe's Archiv für Ophthalmologie, Bd. xxxi., Abth. 4, Berlin, 1886.

treatment to eye diseases, especially to the after-treatment of cataract extraction. The members of this Society who were present at the International Congress held in London in the year 1881 will well remember the communication on the antiseptic method in ocular surgery made by Professor Horner of Zurich, in which communication he said that loss of eyes following a perfectly normally performed extraction of cataract had long been known, and that an exact analysis of all the cases of primary suppuration after cataract extraction leaves no doubt that it depends on infection. The most complete analysis of the results of cataract extraction shows a loss of 10·1 per cent. by the flap operation, and a loss of 4·8 per cent. by the linear operation, which loss has been reduced at Zurich to 1·5 per cent. by strictly observing the measures of antiseptic treatment. This is a wonderful practical result of what is rightly called Lister's antiseptic method.

But Lister's method was not only fruitful in a mere practical sense; it has greatly contributed to thorough investigation of all those living germs which occasionally invade the human body; it gave rise to the question, What are these living germs? The profession in all parts of the world has earnestly tried, and is still trying on a large scale, to give an answer to this question. This research has originated quite a new science, called bacteriology. Bacteriology has already determined a great number of different species of these micro-organisms, and has described their forms, their food, their manner of living, &c.; but it is impossible (and in the meantime useless) to give here an exhaustive account of the systematical differences of these microzoa, and of the multitude of names given to them. Some of them, there is no doubt, are very dangerous to health; some are, perhaps, innocent; and some (why should it not be so?) may be of a salutary influence. For our purpose it will be sufficient to divide them into only two classes, the pathogenic and the non-pathogenic microzoa. For this distinction we can only refer to experiments made on animals. If there is an effect produced by any microzoon on the eye of an animal, then it may be argued that a similar effect may be expected upon the human eye. Rabbits are the most docile and the most patient of animals, and therefore are mostly used for such experiments. Hence any microzoon will generally be called "pathogenic" which leads to infection in the rabbit's eye, and will be called "non-pathogenic" if in the rabbit's eye it does no harm, so that what results in the rabbit's eye will show us what is to be expected in the human eye under similar circumstances. But here we are on uncertain ground. These conclusions evidently are correct only on the assumption that the tissues of the rabbit's eye and the tissues of the human eye are absolutely identical. This, to be sure, is not the case. There are some microzoa very dangerous to rabbits and relatively innocuous to the human body, whilst others are dangerous to human health and relatively innocuous to rabbits. Gonococcus and staphylococcus aureus, for instance, the most dreaded of all microzoa because of their great tendency to provoke suppuration, are in the rabbit's eye relatively indifferent micro-organisms. The conjunctiva of the rabbit and the conjunctiva of the human eye are therefore not equally good abodes for certain microzoa. It is the same with other animals; each one has its own idiosyncrasies for nourishing and for starving micro-organisms. But not only is the difference of the same tissue in different animals the reason of a different behaviour of the same microzoon; the tissue itself in one and the same individual may change under different conditions of life, and may consequently not be identical during the whole lifetime. It is quite possible that changes may take place during life, unknown perhaps to ourselves, but very important to the respective micro-organisms. I will only allude to vaccination, which evidently changes the nutrient soil so that the microzoa of small-pox can no longer live in it; they no longer find nourishment, and the vaccinated body remains unaltered by an infection which would have been fatal to it if unvaccinated. These views introduced concerning small-pox by Dr. Jenner are now about to be generalised for nearly all infectious diseases. It may be ascertained, as a matter of observation, that certain micro-organisms cannot live in an animal when certain others have already taken possession of its body, whereas they may be pernicious to it when certain others are not present.[4] But it has not yet been ascertained whether they change the nutrient soil into a sterile one, or whether they devour or kill each other.

There is one other remark to be made—that is, that the quantity of microzoa invading the human body is also of great importance. Just as poison has its poisonous property only with respect to the quantity, and can be a wholesome remedy when taken in right proportions, although deadly when taken in too large a dose, so a small quantity of pathogenic microzoa, assaulting the human body, may be innocent, whereas the danger increases with the increasing quantity.

If it is true that not every nutrient soil is equally well adapted to every microzoon, one microzoon developing better in one soil than in another, it must consequently be true that one or other nutrient soil is exceedingly well adapted to a certain species of micro-organism. Supposing this to be a fact, some authors have formed the idea that an exceptionally well-nourished and well-developed microzoon might show some difference from the same microzoon when badly nourished, and might, for instance, grow larger and thicker, or even change somewhat its original feature, or change its character in so far as its pathogenic activity might be lessened as well as strengthened. This idea is, to a certain extent, analogous to what daily experience teaches with respect to plants and animals. Plants put in a favourable soil may grow excessively well, and may, to a certain extent, change their colour, smell, and other qualities, but, put in a bad and unfavourable soil, they will fade and die.

Concerning the microzoa this may be the same, but it has not yet been sufficiently proved by facts. We will now briefly consider some of the microzoa which produce diseases of the eye.

The Normal Conjunctiva.—The surface of the normal conjunctiva is covered with a fluid, which is composed of pure water secreted by the lacrymal gland, and of some fat and slime secreted by the minor glands of the conjunctiva. The germs of all living microzoa floating in the air can every moment drop into the open eye and remain on the surface of the conjunctiva. Hence it cannot be astonishing that one finds in every normal eye plenty of germs of all possible kinds of micro-organisms. Of two persons with quite normal conjunctivæ it has been found that almost always one eye contains pathogenic germs.[5] Why does not the eye, then, become inflamed every moment? Conjunctivitis is, as you know, a very common disease. That it is not much more common than it really is, and that it does not arise every moment, may partly be explicable by the passing of these germs through the lacrymal canals into the nose, where they probably may be innocuous; partly by the qualities of the conjunctival tissue itself, it being, in some people, a bad soil for nourishing and feeding germs, in others a good one. The most common of all forms of conjunctivitis is the phlyctenular, called by the authors of a more remote period conjunctivitis scrofulosa. This is a form arising chiefly in children, and only exceptionally in adults. The research in finding a particular microzoon in these phlyctenules has not yet been successful—it would require very delicate manipulation; but in the fluid which moistens the conjunctiva there have been found seven or more different forms of microzoa, partly pathogenic, partly non-pathogenic. The authors of a more remote period, who preferred the adjective "scrofulosa," thought this disease to be a blood disease, which occasionally comes out and subsides. There has never been the least doubt in the mind of any practitioner that this disease is nearly always combined with some other symptoms of scrofula, that it arises chiefly in scrofulous children, and that in these children it often becomes so dangerous that the eye is lost. We are far from exactly knowing the connexion which exists between scrofula and phlyctenular conjunctivitis; but it may be that these infectious germs find an easier and better nourishment in an unhealthy conjunctiva than in the conjunctiva of a quite healthy child, the unhealthy conjunctiva being uneven and perhaps better fitted for sheltering micro-organisms. The same argument will explain the frequent recurrences of scrofulous or strumous ophthalmia. As to the treatment of this disease, powdering the eye with calomel is nearly universally adopted as the best remedy, and its use quite harmonises with the bacteriological theory. Calomel, not soluble in distilled water, turns soluble by the addition of some salt. Tears containing a small quantity of salt, the powder of calomel brought into the eye will be, and is chemically proved to be, dissolved into small quantities, and changed into chloride of mercury, this being an excellent

[4] Emmerich: Tageblatt d. 59. Versammlung deutscher Naturforscher und Aerzte, 18 bis, Sept. 24th, 1886, p. 145.

[5] Schelk., Bd. xvi., p. 197.

antiseptic solution. A weak solution of chloride of mercury was formerly a frequently used collyrium for the same eye disease. It is now almost entirely displaced by the subchloride of mercury or calomelas, perhaps because *in statu nascendi* the chloride of mercury may have a still better effect than a weak solution of it has.

Conjunctival Blennorrhœa, or Purulent Ophthalmia.—Another very dangerous parasitical disease of the conjunctiva is blennorrhœa. The micro-organisms residing in the gonorrhœal matter, first discovered by Neisier, and named by him "gonococcus," is identical with the micro-organisms found in purulent ophthalmia. The etiology of blennorrhœa in new-born children is well known, and the discovery of the gonococcus in both diseases further supports their mutual relation. Nitrate of silver is an excellent antiseptic, and it has long ago proved, in various ways, to be well adapted for curing blennorrhœa, or, to speak in modern terms, it is well adapted for killing the gonococcus. It is not only suitable for curing blennorrhœa, but even for preventing it—that is to say, for killing the gonococcus before it has damaged the eye. For preventing this disease, Credé of Leipzig gave the advice to drop one minim of a 2 per cent. solution of nitrate of silver into the eyes of every new-born child. With this preventive treatment he succeeded in reducing the high percentage of 12 per cent. and more of ophthalmia neonatorum in his lying-in hospital to ½ per cent., and even to less than that. I am not sure if it will be advisable to adopt this treatment as a general rule, but its adoption in lying-in hospitals will very likely save a very great number of eyes, especially in those hospitals in which cleanliness is an unknown thing. At the meeting of the Imperial Surgical Society of Paris, on February 21st, 1866, M. Giraldès[6] reported that in the Hôpital des Enfants Trouvés the loss of eyes (sometimes even of life) by blennorrhœa neonatorum reached the enormous number of 80 to 90 per cent.; to-day we are not very far from reducing the number of eyes lost by this pernicious disease of new-born children to zero. This, within twenty years, is really a respectable progress of science.

Trachoma.—That trachoma is caused by micro-organisms seems to be a well-established fact, though all authors are not of the same opinion on this point. The microzoon, described under the name of diplococcus of trachoma, is, as regards its form and configuration, very like the aforesaid gonococcus, only it is much smaller. It represents a very small ball, cleft by a tiny line, which line can only be seen by the most powerful microscopes. This diplococcus can very well be cultivated in different nutrient soils, whereas gonococcus, can only be cultivated in serum of blood; in other nutrient soils it does not grow. The diplococcus of trachoma has its seat inside the trachoma follicles, but outside the cells; whereas gonococcus lives in the cells or at the outside of the conjunctiva—at least, does not enter deeply into this membrane. Diplococcus of trachoma cannot be successfully inoculated into the conjunctiva of rabbits; but it is said that it has more than once been successfully inoculated into the human conjunctiva. Gonococcus, one of the most dangerous microzoa of the eye, is very easily transferable to the mucous membranes of any animal. As to the treatment of trachoma, a variety of drugs has been successively recommended, but sulphate of copper is the one that is most generally in use. In comparison with nitrate of silver it may perhaps be preferable, because it is less energetic and does not act so superficially. Its action certainly proceeds deeper into the tissue, and may therefore be better adapted to reach the diplococcus, which is seated, not on the surface, but in the follicles of the conjunctiva. The method of squeezing, or cutting, or scratching out the follicles has practically proved useful, and is, bacteriologically, quite correct.

Saccus Lacrymalis.—The lacrymal sac is like a reservoir for the fluid secreted by the conjunctiva. This fluid, always more or less loaded with micro-organisms, is stopped by the least impediment on its way to the nose, the sac being thus stuffed with microzoa. Fortunately, they may not be altogether pathogenic; but some of them, or a great part of them, being pathogenic, it will be a very dangerous group in the neighbourhood of the eye. When the sac is filled up, the outlet to the nose being closed, the fluid may occasionally regurgitate into the conjunctiva, and can greatly endanger its safety, being innocuous only when it contains non-pathogenic organisms alone. [illegible] presence of a stricture in the lacrymal duct, and a filling up of the lacrymal sac with matter, have long since been considered a dangerous complication. Practically, it will always be advisable to pay great attention to this complication, the relative quantity of pathogenic and non-pathogenic microzoa being changeable. The least wound of the cornea, the least loss of its epithelium, as well as any operation, opens an entrance into the deeper layers of the cornea, and allows of the immigration of micro-organisms. The result of this, the microzoa being pathogenic, will be a grave suppuration.

There exists a form of keratitis, called ulcus serpens and keratitis-hypopyon, whose dangerous course, well known to the profession, can hardly be explained except by infection.

Keratitis Mycotica.—The first time we met with the term "keratitis mycotica," which means inflammation of the cornea, caused by micro-organism, was in the year 1875. At the ninth meeting of the Ophthalmic Society, Professor Horner of Zurich demonstrated the cornea of a patient who died in consequence of a facial erysipelas, having suffered in the last days of his life from a large ulceration in the lower part of the cornea. The microscopical sections of this cornea seen with the naked eye showed a great number of fine straight lines running out from the ulcer in a centrifugal direction; seen under the microscope, this network of straight lines proved to be dilated lymph canals of the cornea filled with numerous minute spherical bodies, all of about the same size. The members of the Society who were present were persuaded that this case was really of a mycotic character, and that the spherules seen in the cornea were specimens of the coccus of erysipelas.

There are still other diseases of the eye probably depending on parasitical infection. Microzoa have been found in a chalazion; they have been seen in the internal parts of the eye—in the iris, in the choroid, in the ciliary body, in the optic nerve; local and general tuberculosis have been successfully produced by inoculating the bacilli of tubercle into the anterior chamber of a rabbit's eye; it has even been tried to prove that sympathetic inflammation is produced by the wandering of micro-organisms along the optic nerve and through the chiasma to the other eye; but all this is not yet sufficiently explained, and much laborious and long-continued work is still required. Bacteriology is at the present time a very young and incompletely developed science; it cannot yet answer all the numerous questions arising every day.

The result of all this long-continued work may be that some day the etiology of human diseases and bacteriology will be found to be nearly identical sciences. Everywhere one finds micro- and macro-zoa persecuting, vexing, and killing each other; everywhere one finds parasitism; and, in the material sense of the word, the human race itself is nothing less than a parasite on the surface of the earth. For saving his own life, for nourishing his own body, the human being destroys and kills every creature—plants as well as animals—if he deems it proper for his own welfare. And he is allowed so to do by the words of the Holy Bible. This state of things in the material world corresponds exactly to what your great philosopher Hobbes calls a "bellum omnium contra omnes." But in a moral and intellectual sphere this sentence is out of place, and has to be altered into "pax omnium inter omnes," for in the moral and intellectual sphere there exists no personal interest, no parasitism; the single person being an integral member of the great body of mankind, who has, as such, to seek for knowledge of the works of our Creator, and consequently to admire and to love Him.

GUILD OF ST. LUKE.—A service in connexion with this Guild will be held in St. Thomas's Hospital chapel on the 7th inst., at 5.30 P.M. This is the first of a series of services which the Council is anxious to organise for the purpose of putting forward amongst medical men and medical students the objects of the Guild and its medical missionary work. The sermon will be preached by the Bishop of Lincoln, and no tickets are required for admission.

THE SMALL-POX EPIDEMIC AT JAMAICA.—Despatches were received at Plymouth on the 28th ult. to the effect that the small-pox epidemic at Kingston, Jamaica, is greatly on the increase. The authorities are now adopting stringent measures to check the disease, and infected houses are placarded with yellow bills notifying the fact. The disease has been stamped out in Colon, which is reported to be very

A Clinical Lecture

ON THE

PATHOLOGY AND TREATMENT OF CHRONIC CONSTIPATION IN CHILDHOOD, AND ITS SEQUEL, ATONY AND DILATATION OF THE COLON.

Delivered at the Hospital for Sick Children, Great Ormond-street,

BY W. B. CHEADLE, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE HOSPITAL; PHYSICIAN AND JOINT LECTURER ON MEDICINE, ST. MARY'S HOSPITAL.

GENTLEMEN,—There is, I imagine, no disordered condition of the body which is so frequently the subject of medical treatment as constipation. Not only are doctors called upon to prescribe for it daily, but every chemist's shop does a brisk trade in aperients; and the public use largely the hundred quack pills in vogue, and dose themselves with these and domestic remedies approved by household tradition. And usually, if there is no mechanical obstruction to the intestinal canal, nothing is easier than to force a free passage through it by calomel and colocynth, or castor oil, or jalap, or croton oil. If one purgative will not do it, another will; or an enema will wash out the *cloaca maxima*—the colon. But this is not the whole question. The exhibition of purges is a very limited portion of the management and cure of constipation. The temporary relief of the bowels is a small matter. If the constipation is only a chance and exceptional difficulty, a free purge may end the trouble and cure the complaint, and this is indeed the usual event; but if the constipation is recurrent, chronic, or habitual and obstinate, it is necessary to go deeper in order to effect a cure—to alter the conditions which give rise to the torpidity of the bowels. The temporary relief afforded by a brisk purge, moreover, if frequently repeated, tends to defeat its own end. The purgatives lose their power after a time. Stronger and stronger drugs have to be used, the position becomes more and more difficult, and the last state of the patient is apt to become worse than the first.

Now the permanent cure of constipation is of great importance to health and to the comfort of life. It may seem a small thing, but even with adults habitual constipation and the necessity for constant resort to drugs are always sources of trouble, of worry, of disordered function in other organs, of chronic fæcal poisoning, of pain and discomfort, sometimes of grave anxiety, and even of fatal complications—e.g., obstruction, ulceration, and perforation from pressure of hard fæces. In children the question is in certain aspects more serious still, for it affects not only present health and comfort, but future development and the working conditions of the alimentary canal for the whole of after-life. There is this difference, further, between the two cases. Injudicious treatment may render constipation confirmed in the case of the adult. In the case of the child it may do this also, but it may do far more, as I shall show presently. It may, and often does, cause such serious injury to the bowel itself that it recovers only after long and careful management, even if the damage inflicted be not permanent and incurable. As a general proposition, it may be said, perhaps, that adults suffer most from the consequences of neglect of constipation, children from the too vigorous and mischievous treatment of it. The treatment of constipation in childhood, then, is a subject of considerable importance. To be successful it must comprise something more scientific and comprehensive than the mere administration of aperients. It is not enough to open the canal when blocked, or sweep it clear of accumulations which have lodged there. The essential point is to establish such a habit of daily evacuation that accumulation of the noxious waste and its evil consequences may not recur—to modify the condition permanently. In order to do this the causes which give rise to it must be thoroughly understood—must be removed, or neutralised, or compensated.

There are many different factors concerned in the production of constipation, which act in varying degree in different cases. 1. Deficient fluid in the intestinal canal, caused by deficient supply in food, excessive waste, or deficient secretion from the intestinal mucous membrane. 2. Deficient peristalsis, especially of the large intestine, from defects of diet, or from atony due to over-stimulation by purgatives or to degeneration of the muscular coat. 3. Inhibitory influences of the nerve centres of the brain and cord, probably affecting both peristalsis and secretion of fluid. 4. Deficient bodily exercise and movement. 5. Dilatation of the intestine, especially the colon, due to debility of the intestinal wall or to actual dilatation by accumulated fæces, gaseous distension, repeated enemata, or laxness of the abdominal wall.

Such are the chief causes which give rise to constipation. They are not all met with in the case of children, however—at least not in equal degree. Thus, weakening of the muscular fibre of the intestine by the deterioration of age, mental depression, deficient bodily exercise, or astringent food rarely can be credited with the production of deficient peristalsis in early life. Putting aside malformation, such as atresia more or less complete, peritonitis, intussusception, and the like, the causes which are chiefly operative in childhood are:—1. Food which leaves little residue; very completely digestible food—e.g., milk: fæcal matter too small to duly excite peristalsis. This is a common cause in very young children, and in like manner a too great uniformity of food fails to excite peristalsis. 2. Deficiency of liquid in food, not enough to drink, is another not infrequent cause in children: causing too dry fæces. 3. Deficient biliary secretion, "acholia": unstimulating fæces. 4. Deficient secretion of glands of mucous tract: dry fæces. 5. Over-stimulation and consequent atony of intestine: loss of excitability and loss of power, caused—(*a*) by coarse foods, (*b*) by frequent purgatives, (*c*) by too frequent use of enemata. To these may be added the dread of evacuation from pain caused by hard stools. The latter is frequently operative in children. Instead of aiding the evacuation of the bowels, the child resists it with all its might. This resistance to the passage of fæces, partly voluntary and partly reflex, is caused by the pain of extrusion through the sphincter of a hard rough mass, or the existence of a fissure or sore of the anus. When once constipation has occurred this is an important cause of its continuance, to be overcome only by inducing absolute liquidity of stools for a time.

Now, the symptoms produced by retention of fæcal waste in the intestine vary remarkably. In some cases, especially in very young milk-fed children (and the fresher and better the cow's milk the more constipating is it—i.e., non-fermenting, not acid), there may be absolutely no derangement of general health. The child eats well, sleeps, is hearty and robust—the picture of health. There appears to be no fæcal poisoning by reabsorption of foul matter from the intestine. The chief difficulty is the pain caused by the passage of the hardened dry fæces. This causes the child to resist all attempts to go to stool. It screams and cries, and dreads the action, and thus, refusing to assist by its own efforts, the bowels remain closed for days perhaps, until a good dose of castor oil or other domestic medicine compels evacuation. In addition to this there may be restlessness and night terrors; but the tongue is usually clean, and digestion and nutrition good. Let me give a few examples of this simplest form.

CASE 1.—H. P—— came to me in December, 1880. He was a plump, rosy, sturdy boy of one year and nine months old. Nothing could have been more perfect than his development and nutrition. His limbs were straight, his body well formed, and his flesh hard as wood. He was brought for advice with regard to constipation, from which he had suffered since he was three months old. He was restless and fidgety, had disturbed sleep, waking up crying or screaming. He had been brought up largely on cow's milk. The stools were light, hard, and dry. All kinds of medicine had been given from time to time—castor oil, rhubarb, senna, jalap, scammony, with stimulating articles of diet—porridge, [illegible] times the bowels did not act for [illegible] a time the bowels were [illegible] longer and stronger doses

being required. For the last two or three weeks medicines had been found to produce so little effect that enemata had been resorted to. The child dreaded the action of the bowels, and could not be induced to try to relieve them. He screamed and struggled violently if made to attempt it. He screamed when the motions passed. He dreaded the enemata too. Sometimes these were retained and did not act. The abdomen was full and distended, but no fæcal accumulation could be felt, nor was the colon obviously dilated. The case was one of constipation, due in the first instance to the digestible ingesta leaving a small residue, and thus exciting imperfect peristalsis; partly also to defective intestinal secretions, made worse by stimulating purgatives, and aggravated still further by frequent enemata. As the bowels had not acted for four days, it was necessary to relieve them at once. For this purpose I gave a grain and a half of calomel and four grains of compound jalap powder. But the essence of the treatment consisted in securing daily action by means of some unstimulating aperient. The plan adopted was this: a solution of carbonate of magnesia (two drachms to the ounce) was ordered, and one, two, or three teaspoonfuls, or more, as might be necessary, in milk, once or twice a day every day until the bowels became relaxed. The result was satisfactory. The bowels began to act regularly; the treatment was continued for three or four months. Then the medicine was omitted altogether, and after a time a relapse came. A mixture of strychnine, iron, and sulphate of magnesia was then given as the child grew older, and it became steadily better, and ceased to attend. Thus by simple means, without the use of any strong purgative, except a dose of calomel and jalap at first, and a single dose of calomel (three grains) afterwards, a satisfactory cure was effected in a most obstinate case of long standing, where previous treatment had failed. Of such cases I could quote any number, but I will give only one more.

CASE 2.—Mrs. T. S——'s baby, a fine healthy child of six months, brought up on cow's milk. The food agreed perfectly, but constipation had been obstinate from birth. This was treated at first by occasional doses of castor oil. Then enemata were resorted to. They became required more and more frequently, and larger and larger ones given, until the parents, becoming alarmed, brought the child to me. There was no malformation; there were no symptoms except screaming from passing hard dry fæces. Think of this poor little baby of six months old having its intestine steadily dilated by enemata daily. A solution of carbonate of magnesia (ten grains to the ounce) was ordered, as many teaspoonfuls to be given as necessary to render the bowels relaxed. This was accomplished in six days. The medicine was gradually reduced, and the constipation did not return. Six months later the child remained well.

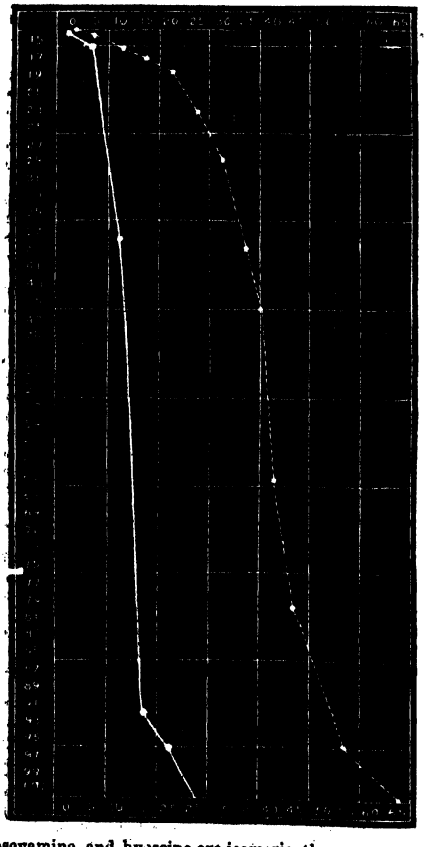
In other cases, again, there is some disorder of health, slight, but significant and persistent, and due no doubt to chronic fæcal poisoning—such as general cachexia, a sallow complexion, somewhat coated tongue, foul breath, loss of appetite, languor, general torpidity and sleepiness, with disturbed nights, dreaming and restless, and in young children moaning and night terrors; of this the following are examples.

CASE 3.—C. J——, aged thirteen, an anæmic girl of delicate appearance, came to me in August 1885, suffering from constipation of the most obstinate kind. The bowels had not been open for ten days. The trouble commenced nearly four months previously, after an attack of mumps. The bowels did not act for three or four days at that time. Castor oil was given, which produced free evacuation. The bowels, however, did not act again for the next five days, when a doctor was consulted, who prescribed more purgative medicine. This ceased to have effect, although various aperients were tried. Then galvanism and regular enemata were given, with varying and temporary benefit. Other medical men were consulted. Various remedies were given, with stronger purgatives. She had been taking jalap chiefly. But for some days no action whatever had followed. The medical man under whose care she was stoutly declared that the girl was imposing upon the credulity of those round her, and that the bowels really had acted, but that she had concealed it. The girl was delicate, slightly made, and rather pallid. Her tongue was fairly clean; but she was extremely languid, and had no appetite; this had been so ever since [illegible] sensible, and the [illegible] served nothing [illegible] established, and had appeared regularly for the last twelve months. On examination the abdomen seemed normal in most respects, but a soft doughy mass could be felt in the left iliac region—clearly accumulated fæces. This was an instance in which the tonicity of the intestine had been lowered by the debilitating influence of mumps, causing deficient peristaltic action. The condition had been increased by the free and long-continued use of stimulating purgatives and enemata. An ounce of castor oil was ordered immediately, to be followed by an oil enema if necessary; after that a mixture of strychnia (three minims) and belladonna (quarter of a grain), with the sulphates of magnesia and soda, twice a day after food. The oil acted freely next day. The mixture produced an action every two or three days. The sulphates of soda and magnesia were persistently increased until the bowels acted freely—until, indeed, an opposite condition of slight diarrhœa was established. Then the amount of medicine was slowly reduced. In a week or two the patient was able to give up medicine altogether. Her health returned, appetite came back as the regular action of the bowels was re-established, and a visit to Brighton confirmed the cure. I saw this girl only a few days ago. She has remained absolutely well.

In this instance the affection of health was only slight. In the next I shall relate the cachexia induced was more marked, and disappeared in like manner with the removal of constipation.

CASE 4. M. L——, aged ten, a small delicate boy, came to me in April, 1883, suffering from frequent attacks of nausea, giddiness, headache, loss of appetite, and languor. He was a quick boy, fond of school, but unable to work there often on account of headache. Physical examination showed nothing wrong, except that he was lean, sallow, and cachectic-looking. The abdomen was not distended. The heart and lung sounds were normal. There was no albumen in the urine. The tongue was a little coated. The only previous illness of importance was an attack of diphtheria; but this was not severe, and there had been no sequelæ. The bowels were always confined, being open only every other or every third day. The stools were hard and dry. The constipation was habitual; it had existed more or less for years. It had been relieved by occasional purges and frequent enemata. The boy was an only son of French parents, indulged by too luxurious living, taking meals with his parents, and partaking of rich dishes and pastry, of which he was inordinately fond.

This was a case in which there was defective peristalsis, not traceable to any definite cause. Possibly the diphtheria may have been one factor by lowering the tone of the intestinal muscle, although it could not be certainly traced to this cause; or the condition may have arisen in simple neglect to empty the bowel daily, and it had been aggravated no doubt by the use of strong purgatives and frequent enemata. The cachectic state and failure of appetite, too, had been increased by injudicious feeding, and this again, had reacted in increasing constipation by inducing malnutrition and debility of muscle of bowel. The headache was a striking feature in this case. It must be referred, I think, to fæcal absorption. The great majority of so-called nervous headaches in children are of this kind. Even in neurotic children constipation is constantly a chief factor in their production. A mixture of sulphate of iron, magnesia, and soda, with liquor strychniæ, were given twice a day after food. The diet was most strictly regulated, and fresh fruit made an important item of food. The saline aperients were increased until a free daily action was secured, and in three weeks all headache and nausea had passed away, appetite returned, and the child was well, except for a little restlessness and grinding of the teeth at night. It was thought that this might be due to the presence of a worm, and a dose of santonine and calomel was given, with the result of bringing away a single round worm. This removed the last signs of disorder. The laxative was gradually diminished, and ultimately left off altogether at the end of two months. The boy continued well until the following December—i.e., six months later, when the constipation returned, and with it the old symptoms of languor, loss of appetite, and headache. A pill of aloes, nux vomica, sulphate of iron, and extract of henbane was now ordered twice a day after food. The bowels acted again, and the child got well without [illegible] her trouble. There has been no return.



(To be concluded.)

ON THE MYDRIATIC PROPERTIES OF HYDROBROMATE OF HYOSCINE.

BY JOHN TWEEDY, F.R.C.S.ENG.,

PROFESSOR OF OPHTHALMIC MEDICINE AND SURGERY IN UNIVERSITY COLLEGE, AND SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL.

THE researches of Ladenburg have shown that three different mydriatic bodies are contained in the atropaceous alkaloids—namely, pure atropine in belladonna and stramonium; pure hyoscyamine (crystalline) in belladonna stramonium, hyoscyamus, and duboisia; and lastly, hyoscine, which is associated with hyoscyamine, in hyoscyamus. Pure duboisine is identical with pure hyoscyamine. The relationship which scopoline, another atropaceous mydriatic obtained from Scopolia japonica, bears, chemically and physiologically, to those just mentioned, has not, I believe, up to the present been precisely determined. Though atropine,

hyoscyamine, and hyoscine are isomeric, they possess somewhat different physical, chemical, and physiological properties. The last named, hyoscine, is the most recent of these therapeutical agents, and appears to have been little used in England. In America, on the other hand, it has been extensively employed, chiefly on the recommendation of the very elaborate experimental and clinical investigations of Professor H. C. Wood of Philadelphia. In the current (November) number of *The Practitioner*, Dr. Mitchell Bruce has called attention to the remarkable efficacy of hyoscine in controlling "those conditions of cerebral excitement variously known as delirium, mania, and insomnia, with restlessness." The prompt and satisfactory results which Dr. Mitchell Bruce had obtained suggested a special trial of hyoscine as a mydriatic.

In commerce there are three crystalline salts of hyoscine: the hydriodate, the hydrobromate, and the hydrochlorate. The first occurs in large prismatic orange-coloured crystals, which are not freely soluble in water; the hydrobromate in small crystals, which are readily soluble in water. Partly on this account, and partly because the hydriodate might contain free iodine, the hydrobromate seemed better suited to ophthalmic purposes. The experiments whose results are here recorded were made with a solution of the latter salt of the strength of 1 in 200, prepared by Mr. Martindale of New Cavendish-street. The solution proved to be a rapid, powerful, and unirritating dilator of the pupil alike in the healthy and in the inflamed iris, and a paralyser of the accommodation. Notwithstanding its great activity when given internally or subcutaneously, I have not yet met with an instance of its producing toxic effects such as occasionally follow the use of duboisine, though this contingency may be possible with stronger solutions. Having tested the general mydriatic action of the drug in healthy and in diseased states of the eye, I asked Mr. E. T. Collins, senior house-surgeon at the Moorfields Ophthalmic Hospital, to undertake some comparative observations with a solution of atropine of corresponding strength. The results of his observations are shown in the annexed diagram. The horizontal rows of figures indicate the time of action in minutes, the vertical column the position of the nearest point of distinct vision (*pp*) in centimetres. The effect of the hyoscine is represented by the continuous line; that of atropine by the broken line.

Before applying the solutions, the "nearest point" was ascertained to be at 15 centimetres in both eyes. Hyoscine was applied to the right eye, and atropine to the left. Hyoscine removed the nearest point to 38 centimetres in ten minutes, whereas it took the atropine thirty-five minutes to do this. In twenty-five minutes the accommodation was completely paralysed by hyoscine, the nearest point having receded to 100 centimetres; whereas with atropine this was not attained for sixty-five minutes. Similarly, the pupil was fully dilated by hyoscine in fifteen minutes, while it required twenty-five minutes to produce an equal effect. (See diagram.) Further, the effects of hyoscine also last longer than those of atropine, and are not so easily counteracted by eserine.

The indication seems to be that, if hyoscine is to have a place in ophthalmic therapeutics, it will be chiefly in cases of iritis and in other conditions where it is desirable to produce as much dilatation of the pupil as possible and for as long a time as possible. It is worthy of note that the application of hyoscine to the eye does not seem to cause the unpleasant taste and feeling in the throat which often follows the use of atropine. This circumstance accords with the observations of Dr. Bruce and others, that when given internally it does not produce unpleasant dryness of the throat and skin like atropine.

Harley-street, W.

SOME CASES OF LOCAL NUMBNESS OF THE EXTREMITIES,

WITH COMPARISONS BETWEEN LOCAL SYNCOPE AND "NIGHT PALSY."

BY J. EDWARD SQUIRE, M.D. LOND., M.R.C.P.,

PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR DISEASES OF THE CHEST; PHYSICIAN TO ST. GEORGE'S AND ST. JAMES'S DISPENSARY.

CASE 1.—E. G——, aged eighteen, tailor, came under my care in March, 1884, complaining of numbness or deadness of the fingers and of giddiness. He is a tall, broad-built, well-developed lad, with thick lips, fair complexion, and light wavy hair. The numbness of his hands is not constant, but occurs about once every day, generally about midday. It appears to be induced by washing in cold water when the hands are already cold. Although he washes his hands in cold water when he gets up, this does not make them "go off," as, having just got out of bed, they are then warm." At several of his visits I had the opportunity of seeing his hands in the condition for the relief of which he applied, and the [illegible] was their appearance on one [illegible] the right hand is quite [illegible] of the hand, with the

other fingers, is dark blue, the whole feeling intensely cold to the touch. A needle-prick in the white finger is not felt, and there is no bleeding; in the blue part of the hand the prick is felt. He can move the hand and fingers, but has no feeling in the white part and tingling in the rest. Pulse 60, and fairly strong at the wrist. Soon the blue colour in the back of the hand becomes mottled with bright red (vermilion); this marks the commencement of the return of the hand to its natural condition. The red points enlarge and coalesce, and soon the whole hand is a good colour again, and warmer." During the return to warmth the hands perspire and tingle and feel burning hot. Both hands "go off" in this manner; usually all the fingers are affected, and also the thumbs to a smaller extent. The fingers, when I first saw the patient, never became absolutely white and bloodless above the middle joint. The wrists and all the rest of the body are warm during the attacks. The numbness lasts usually from five to fifteen minutes, and his arms seem weaker for a time after an attack. Between the attacks both the hands and axillæ perspire very freely. The attacks only occur in cold weather. There is no history of nervous diseases in the family, and the personal history of the patient is very good; he states that he has hardly had a day's illness that he can remember. He is the eldest of seven, his parents having been married probably two or three years before his birth. His teeth are notched. When at school he used to have urticaria, but never has that now; and three years ago he had attacks of "fainting brought on by cold air." He thus describes these attacks: first he felt cold on the brow, everything seemed red and then black, and then he lost consciousness and fell. Physical examination: The chest is long, with acute costal angle. The breath-sounds are weak, and the heart-sounds are plainly heard over the right side. The upper border of the cardiac dulness is in the fourth space, and the apex beat is low, being two inches below the nipple and an inch and a half to the inside. The beat is natural and distinct, not by any means heaving, and the sounds are clear and without murmurs. There is no *bruit de diable* in the neck. Spleen not enlarged, and no signs of inter-thoracic tumour. There is no *tache cérébrale*. Temperature 97·6°. Urine very pale (sometimes dark-coloured), free from albumen or sugar; boiling with Fehling's copper solution gives a reddish discolouration with a flocculent precipitate on standing, but no reduction of copper. Under treatment, in which iron was prominent, his condition improved, and on May 7th I made the following note: "He can now generally keep the hands from 'going off' by beating them across the chest, like a cabman, as soon as they begin to get numb; his thimble seems to press on the finger and to start it off on the body side of the rim. The fingers perspire much when he is out walking." The weather continued cold, and it was not till the beginning of June that he was free from the attacks of numbness for the summer. About the beginning of September he had an attack on the weather changing from very hot to chilly. Early in October the middle and ring fingers of the right hand "blistered" during the night. They were bad a week, and when at the worst the fingers were numb. Also on a cold day, when the wrists became numb, an old scratch on the right wrist broke out again, and was bad some days. By October 24th, although the weather was much colder, he reported that his hands were almost always in a glow, and that he felt much better. The fingers kept well, in spite of very cold weather, till November 14th, when the middle finger of the right hand became numb round the old wound after washing. On Dec. 29th, the patient reported that twice during the week he had had an attack of giddiness and partial insensibility. His hands did not "go off," but his feet did. On Jan. 14th his hands became quite numb from the finger-tips to the metacarpo-phalangeal joints. Shortly after this I lost sight of him.

CASE 2.—J. F——, aged sixty-five, tall, thin, and of nervous temperament. Suffers from neuralgic pain, and lately vertigo. Is dyspeptic, with a red fissured tongue. Urine sometimes deposits uric acid. No articular swellings. Knee-jerk well marked. Pulse always slow, mostly below 60. Bowels easily acted upon. Sleep fairly good, but easily disturbed. In June last, while dressing one morning he was alarmed with sudden loss of feeling and power of movement in the index, ring, and middle fingers of the left hand. He rubbed, pinched, and moved them about, but they were, he said, "as dead as a doornail." Soon they were [illegible] right again.

CASE 3.—H. M——, aged thirty-four, a clerk, height 5ft., weight 6st. 4lb. Weak and neurotic; feels giddy while dressing; the limbs tremble; he fears to move lest he should fall. He has a numbness in some parts of his legs and feet; this sensation soon goes. He often wakes with numbness of one hand, mostly the left; this will sometimes come on in the morning, so that he has to pause in his work, fearing also lest he should put the wrong letters into envelopes. No weakness of the right hand in writing. He has defective teeth, phosphatic urine, and often has hay-fever in the summer; has no headache; sometimes hæmorrhage from piles.

CASE 4.—Miss E. B——, aged thirty-two, tall, dark, and pale. Suffers occasionally with neuralgic pain and pulsating noise in the left ear. She has an anæmic bruit, and her teeth are defective. Menstrual period regular, but painful, and for one or two days only. At the end of October, during an attack of neuralgic pain of the left intercostals and in the right arm, one day the right middle finger suddenly became numb and useless, so that she could not hold a plate or feel it distinctly. During the winter she had faceache on the right side and pain down the right arm, which aches while writing, and she fears it may become useless. She suffers much from close desk-work in the summer, and from neuralgia, and wakes up in the early morning with numbness of the right hand and arm, which makes her fear writer's cramp. She has to have the hand rubbed before attempting to get up. This ceased when the health improved, after the removal of some bad teeth on the right side, and on obtaining rest from work and change of air; and she has since continued her duties at the desk without any failure, but has at times temporary fulness of the tonsil, migraine, or facial neuralgia, with photophobia.

CASE 5.—Miss E. S——, aged fifty, stout, florid, and robust. Menopause after typhoid fever three years since. Some flushing of face and fatigue in walking. Good appetite and regular bowels. Suddenly roused in the night by "deadness" of one thumb. This caused alarm, and the thumb was bitten severely "to bring it to." The bite left a mark, but was not felt at the time. This recurred so as to negative the idea of its being the result of pressure on the arm during sleep.

CASE 6.—M. C——, milliner, single, aged forty-nine, tall and dark, neurotic, but otherwise strong and robust. Troubled with constipation. Menopause last year; before that always dysmenorrhœa. Pain in left side and shoulders most days; sometimes it extends down the arm. At times the fingers of both hands become dead half-way up, so that she is obliged to stop work. Sleeps badly, and sometimes is awakened by numb pain in the left arm or in both hands. Before the deadness and the numbness occur she often notices that the fingers look blue. She is conscious also of a numbness round the lips at times, both by day and in the night; and is sometimes told that she has turned blue in the face when this sensation occurs. The heart is healthy. She has seen the lips sometimes pale with this dark look round them; they then look and feel withered, and she has to rub them before they return to their natural sense and colour. She often wakes up in the night with both hands going dead along their ulnar aspects up to the wrist, or half way up the left arm.

Remarks.—All the above cases have a common symptom viz., temporary numbness of the upper extremity—occurring in most of them paroxysmally. Cases 1 and 2 are examples of local syncope or dead fingers, one severe, the other slight; both occurring in men. In the remaining cases, the occurrence of this numbness at night justifies their classification under what has lately been described as "night palsy." In three of these also (Cases 3, 4, and 6) the patients suffered from paroxysmal attacks of "dead fingers" during the day. Slight cases of "dead fingers" are not uncommon. In these, generally on exposure to cold, the finger tips become white and numb, regaining warmth and feeling after a variable time, the return to the natural condition being accompanied by tingling similar to that of chilblains. Such cases, however, rarely attain sufficient importance to cause the person to seek advice for that alone, as was done by the boy whose case I have detailed (Case 1). These cases of "dead fingers" are most commonly found amongst hysterical and emotional women. In one lately under my care the finger tips became numb every morning, and feeling did not return for about two hours. The condition is evidently due to spasm of the arterioles, the cause of this spasm being more difficult to determine. The chief interest in such cases comes from

their relation to some more obscure nervous affections and to those more severe conditions in which the spasm of the arterioles is more lasting, if less complete, so that the continuance of bloodlessness leads to impairment of vitality in the part, or to absolute local death. Such cases are known as "Raynaud's disease," the most severe showing symmetrical gangrene. M. Raynaud, in his thesis,[1] from which much of our knowledge of these conditions was derived, uses the term "local syncope" to describe the temporary bloodlessness and loss of sensation seen in such cases as the one detailed. The condition, in which there is partial stasis, but with sufficient passage of venous blood to prevent complete loss of warmth, he calls "local asphyxia." It is with this latter condition that his name is usually associated, though the essential character of both is the same. In some remarks on a case contributed by him to the Clinical Society, Dr. Barlow says, "The essential clinical note of Raynaud's disease, at all events primarily, is the paroxysmal character of the circulatory disturbance." That will apply equally to local syncope and to local asphyxia. One recorded case of Raynaud's disease was attended with paroxysmal hæmaturia, and in several the urine was dark-coloured or contained blood. In some there has been spasm in the arterioles of the retina, affecting the eyesight, and distinguishable by ophthalmoscopic examination. These indicate vascular spasm in various parts, and probably the same primary cause produces all; but what the condition may be which sets up spasm of the arterioles has still to be determined. The other cases I have described were attended with a peculiar paroxysmal numbness and paresis of the hands, described by several observers lately, and called "night palsy," which has some analogy to these conditions. It is said to occur chiefly during the night, and in women of emotional disposition, or at the menopause, when neurotic phenomena are so common. Its occurrence in men has been noted, and is exemplified in Case 3. The patient wakes up to find the hand numb and cold, with tingling "pins and needles" or absolute pain. There is loss of power, and sometimes blueness and swelling of the hand, due to distension of the veins. Narrowing of the calibre of the radial artery has been described. The condition is always relieved by rubbing. One observer finds it always associated with disorded stomach—a neurosis, be it observed, common at the menopause, another sees it only in anæmic persons; and in several cases overwork is traced as a possible cause. Dr. Liveing mentions the occurrence of a similar numbness of the extremities associated with megrim, as in one of these cases (Case 4). Night palsy then occurs under similar conditions to those found in the subjects of "dead fingers," and like the latter it is paroxysmal; in its severer forms it produces coldness of the affected part with diminution of the arterial calibre. Dr. Ormerod,[2] when describing night palsy, mentions its similarity to Raynaud's disease, and emphasises the points of difference. I should be inclined to look upon night palsy, local syncope (or "dead fingers"), local asphyxia, and even symmetrical gangrene, as phases of one and the same morbid condition, the severity of the case, or the time at which the symptoms occur, determining for each under which name the neurosis shall be described.

Seymour-street, W.

THE PROSTATE MUSCLE.

By REGINALD HARRISON, F.R.C.S.,

SURGEON TO THE LIVERPOOL ROYAL INFIRMARY, AND LECTURER ON CLINICAL SURGERY IN THE VICTORIA UNIVERSITY.

IN previous communications[3] I have drawn attention to the nature and causation of prostatic hypertrophy. There are one or two points arising out of these to which I should like to refer.

We have been too much accustomed to regard the prostate from its post-mortem aspect—that is to say, as a mass of muscle about the size and form of a chestnut, in which is contained some secreting tissue. It will be as well clearly to understand that under no circumstances during life, save the rare and momentary one when the bladder is absolutely empty, does the healthy prostate present such a form as that referred to; on the contrary, the muscular fibres of which it is largely composed are spread out like a funnel, so as to form an ample support for the bladder and its varying amount of contents. The degree to which it is spread out is, of course, relative to the contents. Hence the action of the prostate may be said to be just as continuous as that of the heart. This is a point which can be readily determined by examining persons in different bodily positions, and under varying circumstances so far as the contents of the bladder are concerned. If a person is examined by the finger in the rectum when he is in a semi-erect position, with a healthy prostate and some urine in the bladder, it will be found that the limits of the prostatic area are bounded on either side by a marked ridge of muscular fibre in a state of more or less tone, whilst the centre of this area is softer and more yielding to the touch. In making an examination of this kind for the first time, and taking our idea from what we have previously learnt in the dissecting-room, we naturally expect to find the converse of this—namely, a rather hard centre, which gradually loses its definition as the finger passes towards the sides. It is a matter of common remark that, unless the prostate is diseased, a surgeon has to examine it a good many times before he thinks he can realise what he has learnt as a part of his anatomical studies.

We may, I think, conclude that the primary function of the prostate is that of supporting and controlling the outlet of the bladder. Where there is no such function to fulfil, the prostate muscle is only met with in a rudimentary form, as we see in cases of extroversion of the bladder where there is no receptacle for the urine. In advanced life, so far as I have been able to ascertain, hypertrophy of the prostate in these malformations never occurs.

That this is the principal function of the prostate is further indicated by what follows wounds inflicted on the urinary tract from the bladder downwards. The only incision that renders a person absolutely incontinent for a time is when the prostate muscle is involved. Openings made into the membranous urethra, either for exploration or for median lithotomy, are not followed by incontinence unless the prostate has been temporarily paralysed by over-distension with the finger. In lateral lithotomy the continence of the bladder by the action of the prostate is maintained to the last moment of the deep incision, when the gush of urine will often carry the stone into the jaws of the forceps. Nor does continence return until sufficient time has elapsed for healing to take place.

I have met with several cases where stones in the bladder have occupied unusual and somewhat remarkable positions relative to what may be regarded as the laws of gravity. I refer to those instances where the calculus is lodged in a sort of space hollowed out above the pubes. On two or three occasions I have had to reverse the blades of the forceps to extract stones from this position, and I have twice recently met with instances where the sound passed beneath calculi thus placed without giving a clue, and thus causing errors in diagnosis which this knowledge enabled me to correct. From my observation of calculi in the bladder I am disposed to connect their occasional supra-pubic position with the upheaving movement of the floor of the viscus, which is constantly, though imperceptibly, going on, principally through the medium of the spread-out muscular fibres of the prostate. From the dissecting-room standpoint it would seem almost impossible to understand how a healthy prostate could influence the position of a stone in the bladder in the slightest degree; when, however, we learn to recognise how differently the muscle is disposed and occupied during life from what we previously believed, it is not difficult to see that a vermicular movement of the muscular floor of the bladder, which is constantly going on, might tend to lodge and fix a calculus above the pubes. It is quite clear, however, that a stone independent of sacculation, occupying a resting-place in the anterior wall of the viscus, must have been put and retained there by some agency. These points will, I think, be found to have their bearing upon the practical surgery of the parts referred to.

VICTORIA UNIVERSITY. — The Manchester City Council on the 1st inst. passed a resolution in favour of a Government grant to Victoria University. It was stated that not a penny had been contributed by the Government either to Owens College or Victoria University, both of which were in need of fin[illegible] assistance, and it was thought that [illegible]vernment had paid £12,000 to [illegible]niversity had some claim.

A CASE OF ALBUMINURIA;

DEATH RESULTING FROM ACUTE ŒDEMA OF THE BRAIN.

BY HENRY WILCOX, M.B., M.R.C.S.

THE following case, which came under my notice while returning from my holiday trip to New York, may be worth publishing, as the carefully recorded temperature throws some light upon the etiology of uræmic coma:—

S. T——, aged fifty-one, a gentleman of spare appearance, florid complexion, looking somewhat older than his age, occupied the seat opposite to me at the saloon table. From my observations, and from several conversations we had together, I found he was in a shattered state of health; his habits were those of a man who for a long time had drunk freely of spirits, giving me the impression that he was suffering from chronic Bright's disease, accompanied by the usual dyspepsia and want of appetite. On the morning of the fourth day of our voyage he appeared to be in better health and spirits than during the previous three days; his skin was clearer and he ate more; later in the day, however, he complained of severe occipital headache. He was not alarmed at this symptom as he had frequently had it before in a milder degree, when it generally passed away in a few hours. He declined to apply for the advice of the surgeon of the ship. Towards the middle of the day, his headache still continuing, he retired to his state-room, with the intention of "sleeping it off," as he expressed it. Nothing more was seen of him until 4 P.M., when the bedroom steward finding him to be sleeping soundly left him undisturbed. At 6 P.M. he was still sleeping, and the attention of the surgeon was called to him. This gentleman (Dr. Coffey) soon afterwards asked me to visit the patient with him. We found he was in a state of profound coma. Our combined efforts failed to rouse him in the least. His breathing was stertorous; face dusky, slightly œdematous; pupils fixed, insensible to light, and the left larger than the right; carotids pulsating strongly; no abnormal sounds about the heart's action; pulse 72, hard; temperature 97°; legs and feet slightly œdematous. We were fortunately able to make an examination of the urine, which, so far as we could learn, had been normal in quantity and general appearance; it was highly albuminous, and we estimated roughly that the deposit, after boiling and the addition of nitric acid, was one-third of its bulk. From these evidences we concluded that the patient was in a state of uræmic coma. Dr. Yarrow of Philadelphia, who was also a passenger on board, endorsed this opinion, and watched the case to the end with us. The treatment we employed was first wet cupping over the loins to twelve ounces; there was no jaborandi on board, but we administered hydragogue cathartics by enemata, subcutaneous injection of digitalis, mustard sinapisms to the nape of the neck and calves of the legs, and occasional nutritive enemata with a little brandy. In spite of our efforts the patient showed no signs of improvement, the coma becoming more profound; convulsive fits came on at intervals, greatly exhausting his vital powers. He died after a severe paroxysm about four o'clock in the morning. During the few hours that we were in attendance we were able to make careful observation of the temperature, which we took constantly in the axilla at intervals of about half an hour from nine o'clock at night until the time of his death. Early in the evening there appeared an initial lowering of the temperature; at 7 P.M. it was 97°; the pulse 72, full, incompressible; carotids strongly pulsating. At 9 P.M. a slight rise in the temperature was noted; it was then 99°. At 10 P.M. it was 100·2°; at 11 P.M., 101·4°; at midnight, 102°; at 1 A.M., 103·4°; at 2 A.M., 105°; at 3 A.M., 107°; and at 4 A.M., 109·2°. The last record of temperature was taken both in the axilla and rectum. The thermometer in the rectum was expelled in the death struggle; it indicated 109.2°, the same as that in the axilla; had it remained longer, a higher temperature would probably have been recorded. As the temperature began to rise the pulse assumed a different character, becoming faster, smaller, and easily compressible; shortly before death it was 135 per minute, and the respiration 38.

The point of interest in this [illegible] remarkable rise of temperature preceded [illegible] between these two cor[illegible] from 7 to 9 P.M., in which the temperature was normal. The presence of urea in the blood, or even its product of decomposition—carbonate of ammonia,—may account for the coma and convulsions, but they have not been found to produce this influence upon the temperature. Variations of temperature, however, in the apoplectic state accord so well with the above that we may fairly assume that our patient died not so much from the toxic state of his blood as from a sudden acute œdema of the brain, with perhaps effusion into the ventricles. This view of the case is, I think, supported by the following considerations:—1. The secretion of urine at the time of seizure was normal or increased in quantity. 2. The sudden onset of cerebral symptoms preceded by intense occipital headache. 3. The strongly pulsating carotids, and full incompressible pulse at the beginning of the attack. 4. The variations of temperature were the same as those observed in cases of cerebral hæmorrhage, in which death occurs in from ten to twenty-four hours.

Woolwich.

LITHOLAPAXY IN MALE CHILDREN AND MALE ADULTS.

BY SURGEON-MAJOR D. F. KEEGAN, M.D. DUB.,
RESIDENCY SURGEON, INDORE, CENTRAL INDIA.

DURING the past two years I have published four papers[1] giving details of a considerable number of litholapaxies performed on male children and male adults at the Indore Charitable Hospital, Central India. At a time when the treatment of stone in men, women, and children is attracting so much attention in Europe, by reason of the revival of the "high" operation, perhaps it may not be amiss if one who has enjoyed considerable opportunities of treating stone in India were to place before his professional brethren in England his experiences of litholapaxy in male children and male adults. I advocate litholapaxy in preference to lateral lithotomy in the treatment of the great majority of stones we meet with in male children, principally for two reasons—viz., rapidity of cure and absence of a cutting operation. Litholapaxy as applied to the treatment of stone in male children, being a new departure in surgery, must undoubtedly be submitted to the accumulated experience of practical surgeons in all parts of the world before a positive conclusion can be arrived at as to its practicability and value. I therefore beg to submit to the judgment of surgeons in Great Britain the record of a considerable number of litholapaxies performed on male children in India. Having discussed this operation in its application to the treatment of stone in boys, I shall subsequently deal with some points of interest connected with its performance in the adult male. Believing, as I do, that Bigelow's operation will, in the near future, supersede to a very large extent lateral lithotomy in the treatment of stone in male children, I am all the more anxious on that account that my predecessor at Indore, now retired, Deputy Surgeon-General T. Beaumont, should obtain the credit of having originated the idea of the feasibility of practising litholapaxy in boys. I, however, was the first to put his ideas on this subject into practice. He had performed six lithotrities successfully on male children at Indore prior to my succeeding him, and had ordered to be sent from London lithotrites and evacuating catheters suited to the performance of litholapaxy in boys a few months before he left Indore for Hyderabad in the Deccan. He was not the first to perform litholapaxy in boys, simply because he had not an opportunity of doing so at Hyderabad; but had he remained on at Indore he would undoubtedly have put his ideas into practice at the first favourable opportunity. Soon after my joining my present appointment at Indore the lithotrites and evacuating catheters suited to the performance of litholapaxy in boys arrived from London, but I must confess that for some time I hesitated to use them. Like many surgeons practising in India, lateral lithotomy in male children had hitherto proved a very successful operation in my hands, and therefore I was naturally somewhat loth to change it for any other method of removing a stone from a boy's bladder. However, in December, 1881, I performed

litholapaxy successfully on a boy aged five years. In the succeeding year I operated on two boys by this method. During the years 1883 and 1884 ten and twelve boys respectively were subjected to litholapaxy at the Indore Hospital. During the year 1885 we performed twenty-seven litholapaxies on boys; and between January 1st of the present year and the end of March, when I left India on furlough, six boys were operated on by Bigelow's method at this hospital. We have therefore performed fifty-eight litholapaxies on boys at Indore since I began this operation on male children at the close of 1881, and we have lost one case. Cases 12 and 13 in the table appended were performd by my assistant Mr. Gunput Singh; and my friend Surgeon-Major Caldecott, during my absence from Indore, performed nine operations of this series, beginning at No. 41 and ending at Case 49. Case 11, the only unsuccessful one, was operated on in the first instance by my assistant, and on two subsequent occasions by me. All the other cases in this table were performed by me alone. That litholapaxy is capable of dealing successfully with stones of considerable size occurring in male children is, I think, proved by the facts detailed in the accompanying table; and from what I have already stated it will be seen that I practised litholapaxy in male children very tentatively at first, and as time went on, and I had gained more experience, I gradually increased the scope of this operation.

Now, what are the conclusions at which I have arrived after nearly four and a half years' experience of litholapaxy in the treatment of stone in male children? I may at once answer this question by stating that, with my present experience of this operation in boys, I would almost as soon think of performing lateral lithotomy on an old man the subject of a small, uncomplicated stone as I should think of performing lateral lithotomy on a boy whose urethra would readily admit the passage of suitable lithotrities and evacuating catheters, and whose stone was neither abnormally hard nor large. The only cases of stone in male children which I nowadays reserve for lateral lithotomy are those in which litholapaxy is contra-indicated by reason of the existence of a very narrow urethra or the presence of an unusually hard or large stone. I am well aware that in advocating litholapaxy in the treatment of stone in male children I am running counter to the cherished opinions and judgment of many eminent lithotomists, and I know that some high authorities consider my views on this subject heterodox and dangerous in practice. But facts and figures are on my side, and I can therefore, perhaps, afford to disregard the adverse opinions of those who have never practised this operation in boys. I am anxious to draw a very marked line of demarcation between lithotrity and litholapaxy as applied to the treatment of stone in male children. I hold that lithotrity is an uncertain, tedious, and often dangerous method of disposing of stones in boys, because the surgeon in performing it can never be perfectly sure that he has reduced the stone in the bladder into fragments sufficiently small to pass of themselves readily through the urethra along with the urine, and thus a second operation, with all its train of suffering and dangerous complications, is often a necessity. Indeed, I consider that the success and safety of litholapaxy as applied to children depend in a very great measure in not leaving, if possible, the smallest fragment of stone behind in the bladder. Lithotrity at many sittings, the lithotrity which preceded Bigelow's operation, is happily dead and buried, and is even less suited to the treatment of stone in male children than it is to the treatment of stone in adult males.

The chief objections which have been raised against the performance of lithotrity and litholapaxy in boys, are, as we all know, the undeveloped condition of the genito-urinary organs, the smallness of the bladder, the extreme sensitiveness and liability to laceration of the mucous membrane of the bladder and urethra, and the narrowness or small calibre of the urethra. Let us examine these objections. If by the undeveloped condition of the genito-urinary organs in boys is meant an undeveloped condition of the prostate, this is for the surgeon a decided advantage, as recently pointed out at the Medical Society of London by Mr. W. J. Walsham, when detailing the history of a very instructive case of litholapaxy performed on a boy aged ten. The smallness of the bladder in boys is, in my opinion, not a valid objection to the performance of litholapaxy. The bladder of a boy of even only three or four years of age is, as a rule, quite roomy enough to permit of the efficient [illegible] small lithotrite; and if a medium-size[illegible] of fragments of stone, [illegible] enables [illegible] worked, no injury can be done to this organ by over-distension. The bladders of boys suffering from stone are as a rule healthy, and will stand more distension proportionately to their size or capacity than the bladders of old men. The next objection we come to is the extreme sensitiveness of the mucous membrane of the bladder and urethra. With regard to this objection, I would merely remark that, as litholapaxy is always performed on patients under the influence of an anæsthetic, this objection may be safely disregarded; and I would add, in passing, that it has yet to be proved that the urethra of a boy, say of six years of age, is more sensitive than the urethra of a youth approaching puberty. Indeed, I am inclined to think that the urethra of the latter is the more sensitive of the two. We now come to the liability to laceration of the mucous membrane of the bladder and urethra in boys. Theoretically this may appear a very plausible objection; but in practice it may also be safely disregarded, if the surgeon employs suitable instruments, and is careful and skilful in their use. I have performed nearly fifty litholapaxies in boys, and, as far as I can judge, I have never damaged the mucous membrane of the urethra and bladder; and even if I have done so, no untoward consequences have supervened. We come at length to the last objection to the performance of litholapaxy in boys—viz., the narrowness or small calibre of the urethra. Now, if it were a fact that the size or calibre of the urethra in male children is generally very small, this would, of course, be an insuperable objection to the performance of litholapaxy in these young patients. *But it is not a fact* that the calibre of the urethra in boys of six or eight years of age is, as a rule, very small. On the contrary, the calibre of the urethra of boys of only three or four years of age is sometimes very large, as I shall show later on by citing examples of this fact from the pages of my case-book. True it is that the meatus of the urethra in male children is sometimes very small; but let the orifice be incised, and it will then be generally found that a lithotrite of considerable size will pass readily into the bladder. It may seem somewhat strange that a false estimate of the normal size of the urethra in male children should have existed until very recently; but it is really no more strange than that surgeons should have believed up to the date of the discovery of Otis that the calibre of the adult male urethra was much smaller than it really is. I think that the chief reason why an erroneous estimate of the normal size of the urethra in boys has hitherto prevailed is, that in performing the old operation of lithotrity in male children the meatus of the urethra was seldom divided, and thus the true calibre of the normal urethra in boys was ignored or not noticed. I certainly was unaware of the normal calibre of the urethra in boys until I had practised litholapaxy amongst this class of patients, and doubtless, like other lithotomists, I had failed to recall to mind several occasions on which I had been able to pass staffs of large size into the bladders of young boys preparatory to performing lateral lithotomy. Now, what does the annexed table prove regarding the size or calibre of the urethra in boys? Speaking generally, for there can be no hard-and-fast rule laid down on this point, it shows that the urethra of a boy from three to six years of age will admit a No. 7 or a No. 8 lithotrite (English scale), and that the urethra of a boy of eight or ten years of age will admit a No. 10, a No. 11, and even sometimes a No. 14 lithotrite (English scale). With a No. 8 lithotrite and a No. 8 evacuating catheter it is, I find, quite feasible to crush and dispose of a mulberry calculus weighing between two and three hundred grains in an hour's time. Experience has taught me that there is as great a difference in the size or calibre of the urethra in male children of the same age as we find to be the case amongst adult males. Age cannot always be depended on as the measure of the capacity of the urethra in boys, as I know from experience; indeed, some children of only four years of age have more capacious urethræ than other children of ten. Cases 35 and 36 in the annexed table are examples of this fact. The No. 8 lithotrite did not pass with the same facility into the bladder of Case 35, whose age was ten, as it did into the bladder of Case 36, whose age was only four. In some children of four or five years of age it is unsafe to pass a No. 7 lithotrite, although an instrument of this size will sometimes pass readily into the bladder of a boy of only two years of age. Perhaps I shall best illustrate the size or calibre of the urethra in male children by briefly relating the history of some of the cases in the annexed table.

CASE 17.—S——, a male child two years old, was brought by his mother to the Indore Hospital on March 10th, 1884, suffering from symptoms of stone. On being placed under chloroform, I passed a small steel sound and struck a stone in the prostatic portion of the urethra. Withdrawing the sound, I passed a long urethral forceps and seized the stone. I found, however, that the forceps with the stone between its blades could not be withdrawn through the membranous portion of the urethra. I therefore pushed the forceps with the stone between its blades into the bladder and then let go my hold on the stone. Withdrawing the urethral forceps, I then introduced a No. 7 lithotrite into the bladder, seized the stone, and crushed it readily three or four times. To my surprise, a No. 9 evacuating catheter passed readily into the bladder. I then attached a Berkeley Hill's débris extractor to the evacuating catheter and removed the débris, which weighed seven grains and consisted of uric acid. The operation lasted four minutes, and the child left the hospital perfectly well on March 12th.

CASE 18.—F——, a male child one year and nine months old, was carried in his mother's arms to the Indore Hospital on March 24th, 1884, suffering from stone symptoms which had existed for four months. Being placed under chloroform, the stone was struck in the bladder, and I then tried to introduce a No. 9 evacuating catheter, intending to perform litholapaxy. The evacuating catheter would, however, not pass, so the operation was postponed to the 27th. In the interim a clever and very intelligent native workman, who makes many surgical instruments for me from European patterns, made me a No. 7 evacuating catheter. On March 27th, the child being again placed under chloroform, the No. 7 evacuating catheter passed readily. I crushed the stone with a No. 7 lithotrite, which I introduced into the bladder on three occasions, and removed the débris by means of a Berkeley Hill's extractor attached to the No. 7 evacuating catheter. The operation lasted thirty-two minutes, and the stone, which weighed eighteen grains, was composed of lithic acid. There was not a particle of débris left behind in the bladder. On the 28th the child complained of much pain in passing urine, and the penis was somewhat swollen.—29th: Pain in voiding urine much less. Swelling of penis much diminished.—30th: Pain in micturition very slight; swelling of penis nearly subsided. The mother took the child home.

(To be continued.)

A CASE OF

TROPICAL ABSCESS OF THE LIVER, OPENING INTO THE BOWEL; RECOVERY.

BY SURG. G. HARLEY THOMAS, M.R.C.S.,
ARMY MEDICAL STAFF.

PRIVATE P. L——, 1st Battalion Border Regiment, aged twenty-three years, came under my treatment in the Station Hospital, Kasauli, Punjab, on April 3rd, 1885, with symptoms of hepatitis. He had been in India for more than three years, in a hot station. He had never had dysentery, and was not an intemperate man. He had suffered from hepatitis six months previously at Agra. On admission he complained of pain in the right side, over the hepatic region, which was aggravated on breathing deeply; he had also pain in the right shoulder. He had vomited the day before, and still had a feeling of nausea. His liver was much enlarged, chiefly in an upward direction, dulness extending to about an inch and a half below the nipple; there was only slight enlargement below the ribs, no bulgings of the intercostal spaces, and no jaundice. His temperature was 99·2° in the morning, and 100·6° in the evening. He had no rigors. The pulse was normal, the tongue slightly coated, and the bowels constipated. The disease was diagnosed as hepatitis. A sinapism was applied over the liver, and the following mixture ordered to be taken twice a day: one-sixth of a grain of podophyllin, thirty grains of taraxacum, and one ounce of peppermint water; also to take a five-grain mercury pill, and to be placed on milk diet. On April 5th, his temperature rose slightly, being in the evening 101·6°; his bowels were well open, motions being white in colour. On the 6th he complained of great pain over the liver; his breathing was quick, and his countenance anxious; his tongue had a white coating, with raised papillæ; his temperature was 100° in the morning and 103° in the evening, but he had no rigors. A blister was applied to the right side, the mixture and pill were omitted, and eight grains of chloride of ammonia in an ounce of water was ordered to be taken thrice a day. On the 7th he was better; the temperature was almost normal in the morning, and only rose to 101° in the evening; he perspired freely during the night. His temperature now varied between 99° in the morning and 102° in the evening up to the 10th, when on that date, after having been eight days in hospital, he was seized with a rigor about the middle of the day, and his temperature dropped from 101·2° in the morning to 99·2° in the evening, and pus was observed in his motions for the first time (about two drachms in each stool). A hepatic abscess was then known to exist. On the 11th he felt much better; the temperature remained normal both morning and evening; the pain in the hepatic region was considerably less; his tongue was coated, but moist; he had only one motion, which was dark-brown and semi-solid, and about four drachms of cream-coloured pus were passed with it; his urine was high-coloured, and contained lithates, but no albumen. The chloride of ammonia was now stopped, and the following ordered to be taken three times a day: perchloride of iron, ten minims; simple syrup, one drachm; and infusion of calumba, one ounce. Also some extra milk and eggs were given him. From the 11th to the 23rd his temperature remained subnormal; he had one or two solid or semi-solid motions daily, passing three or four drachms of sanguineous pus with each stool; but on the morning of the latter date he complained of pain below the sternum, his temperature rose to 100·2°, his pulse was 100, and for the last two or three days he had passed no pus from the bowel. A sinapism was applied to the tender spot, and a diaphoretic mixture administered. On the 24th the hepatic pain was considerably less; his temperature remained high, being 102°. He passed a small solid motion, with some thick unhealthy pus. Five grains of blue pill were ordered. On the 25th his temperature dropped to normal again; his bowels were well opened after the pill, the first motion containing a good deal of decomposing pus, but only a trace of matter in the remaining stools. On the 26th his bowels were open twice, and no pus was passed. The temperature and pulse were normal. From this date, and throughout the whole of the month of May, the patient passed small quantities of pus every two or three days (about three drachms with each motion); his bowels were nearly always regular, and his temperature kept normal; but he was still troubled with a pain in the right side, especially when drawing a deep breath, and he could not lie on that side. He was placed on chicken diet, with extra milk and eggs, and sometimes stimulants. During the month of June he progressed very favourably, and began to gain flesh. A small amount of pus was still passed occasionally. The liver had much contracted, the dulness had diminished in front, and his temperature kept normal. In July he was convalescent, his general health and strength had much improved, no pus had been observed in his motions for three weeks, the hepatic pain had entirely disappeared, and on Aug. 2nd he was discharged from the hospital cured.

Remarks.—The above case is an example of great structural changes going on in the liver without the patient being aware that there was anything very serious the matter with him. It was only eight days after admission into hospital that the abscess burst into the bowel, while a few days before admission the man had been marching about ten miles daily, and had enjoyed fairly good health from the time of his discharge from the Agra hospital six months previously. But this is frequently the case when the inflammation of the organ is caused by the combined effects of great heat and malaria. It will be observed that the bursting of the abscess was followed by an immediate fall of temperature, which remained slightly subnormal for twelve days; it then suddenly rose, and this indicated decomposition of pus taking place, especially as none had been passed with his motions for a few days previously to this rise of temperature; but as soon as the unhealthy matter was discharged the temperature dropped to normal again. The previous history [illegible] patitis, which lasted a long time, [illegible] sion between the liver and [illegible] though the abscess burst

quickly after his admission into hospital, the pus was thus prevented from being discharged into the abdominal cavity, and causing his death.

Umballa, Punjab.

CURATIVE TREATMENT OF VAGINAL HYDROCELE BY CORROSIVE SUBLIMATE.

BY JAMES MILLER,

SURGEON TO THE LONDON GASLIGHT AND COKE COMPANY, NINE ELMS STATION; VISITING SURGEON TO THE SOUTH LAMBETH AND STOCKWELL DISPENSARY.

THE treatment of vaginal hydrocele by tapping is so simple that were it *per se* curative instead of being merely palliative, as is usually the case, there would be no need of any further method. But unfortunately such is not the case, and when an individual is tapped for the first time, it is simply one of a series of operations which will have to be repeated from time to time at longer or shorter periods, varying with different persons, and sometimes with the same one.

Various methods for the radical cure have been suggested and carried out, the latest probably being that recommended by Mr. Bellamy[1]—viz., "a clean sweep through all the scrotal tissues from the cord to the base;.....the cavity is then to be stuffed with carbolised lint or gauze, and the upper part of the wound brought together by stitches." But, though undoubtedly good, this is bold treatment, and such as many men would not submit to, for the reason that their hydroceles give them little or no pain, and they are more content to go on with the tapping process now and then than take the risk of the knife. If, however, at the time of tapping, an injection can be used which will cure the hydrocele without compelling the patient to keep to his bed or give up his work for a time, there is a distinct gain upon the various methods of treatment at present in vogue. And such an injection I believe we have in corrosive sublimate, as illustrated by the following cases.

CASE 1.—B. C——, aged forty-five, a stoker, had been troubled with hydrocele (left) for about two years. It was the usual history of a gradual and painless enlargement. Only the inconvenience of having so large a burden in such an awkward place induced him to seek some relief. I therefore tapped him, and the process was repeated four times in two years, there being only an interval of three months between the third and fourth operation, which tended to dishearten him. As he could not afford to lose time and "lay up," I therefore determined to try what the injection of a small quantity of corrosive sublimate would do. Accordingly I prepared a solution of one grain of the salt in an ounce of distilled water, and injected fifteen minims (=$\frac{1}{4}$ of a grain) of this into the sac. The *modus operandi* was very simple. Having evacuated the contents of the sac, I charged a hypodermic syringe of the above capacity with the liquid, and fitted it into the cannula which had been left *in situ*, discharged the contents into the sac, and removed the cannula in the perpendicular. The man felt no more than if he had only been tapped. This was done on Saturday evening, Jan. 3rd, 1885. I saw no more of him until the following October, when, on inquiry about his hydrocele, he informed me that it had all gone; in fact, he had not been troubled with it since I "injected the stuff." He stated that he experienced some sharp pain during the first night, but it passed off, and he went to work on the Monday as usual. On examining the scrotum there was no deformity or enlargement to be seen. It was perfectly natural.

Having another patient troubled with hydrocele, I was therefore glad to know the result of this first case, which, being so satisfactory, I did not hesitate to repeat.

CASE 2.—A. M——, aged thirty-eight. On Nov. 14th, 1885, I treated this patient in the same way. Here, again, was another ordinary vaginal hydrocele (left). Having drawn off twelve ounces of blood-stained fluid, I injected the solution in the same quantity and the same strength as before. In this case, however, I anticipated any after-pain by ordering some belladonna liniment to be sprinkled on lint and applied to the scrotum. On Nov. 16th, there had been no pain, and the patient had slept well at night, but the sac was rather more distended than it was immediately after the operation. I ordered him to keep on the sling which he had worn previously, and in a few days the fluid had been reabsorbed and the swelling was much less. In a few days more the swelling had all disappeared, and has not troubled him since.

In addition to the above cases I have treated two others on the same lines as the last, but there is no history to them. They were injected after evacuation, and disappeared without trouble. The gains by this simple method are great, for though the means used are the minimum for palliative treatment, the result is the maximum of curative treatment, and this without loss of time to the patient, which to most men is a great consideration.

South Lambeth-road, S.W.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum allorum tum proprias collec as habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

CASE OF BILIARY COLIC WITH JAUNDICE OF TWO YEARS' DURATION; EXPLORATORY OPERATION; DEATH; NECROPSY; REMARKS.

(Under the care of Dr. PRINGLE.)

THE following case is one of considerable interest, and will be attentively perused by all interested in abdominal surgery. The condition of the part as found at the time of operation was unusual, and exceptional difficulties were encountered, making it impossible either to remove the stone through the wound or to crush it *in situ*. The gall-bladder lay so deeply that the ordinary method of attaching it to the wound could not be employed, and its position also prevented suture of the incision which had been made in it for the purpose of exploration of its interior. On this account a ligature was applied round the gall-bladder above the incision, the part below being removed, and it was thus hoped that the extravasation of its contents would be prevented. This procedure appears to have been effective until the general cavity of the peritoneum was shut off by adhesions.

Elizabeth L——, a widow, aged fifty-five, was admitted under the care of Dr. J. J. Pringle on Sept. 8th, 1886. No facts of importance in regard to her family history were elicited, except that her mother had died of heart disease, and that four brothers still alive are subject to rheumatism. Her previous health had been uniformly good, interrupted only by seven pregnancies and several attacks of rheumatism, affecting chiefly the small joints of the hands and feet, the most severe of which kept her confined to bed for six weeks in the spring of 1884. In September of that year a varicose vein in the right leg "burst," and during her consequent confinement to bed she was suddenly seized with severe pain in the abdomen, starting from the right side, radiating towards the spine, and becoming general over the abdomen; uncontrollable vomiting accompanied this attack, which lasted two days, and after it her skin and conjunctivæ were noticed to be yellow. Similar attacks, of varying intensity, recurred once or twice a week until April 4th, 1886, when she first came under observation as an out-patient. She then stated that her appetite was good, but that she was "afraid to eat," as solid food invariably caused pain, relieved only by vomiting; her bowels were very confined. Under palliative treatment directed to these symptoms (bismuth, carminatives, saline purgatives), she improved remarkably for nearly three months; but from the beginning of July onwards she had a great number of attacks; her jaundice became deeper; she rapidly emaciated and suffered from sleeplessness, due to her constant pain and mental worry from inability to attend to her domestic and business affairs. Recognising the gravity of her condition she at length con-

sented to her admission into the hospital, and to submit to any measure considered advisable for her.

State on admission.—An intelligent, big-framed woman, with drawn features expressive of pain, dilated facial capillaries, jaundiced tint of skin and mucous membranes, and chronic rheumatic deformity of the joints of both hands and feet. The superficial veins of both legs are varicose, and there is a large number of hæmorrhages into the skin of the lower extremities and trunk with evidences of much scratching, although the patient states that she does not itch now as formerly. Since first coming under observation she has lost flesh greatly. The pulmonary physical signs are normal. There is no physical evidence of hypertrophy or dilatation of the heart, but over the position of the apex beat is a distinct, though soft, systolic bruit conducted towards the axilla. Over the area of the aortic valve is a harsher systolic bruit, distinctly heard in the right carotid artery, and loudest in the first right interspace close to the sternum; the second sound everywhere is sharp and clear. The radial pulse is small, rather incompressible, and beats 88 to the minute. The abdominal walls are lax, permitting thorough examination of the viscera. Hepatic dulness extends a distance of four inches and a half vertically in the nipple line from the sixth rib to an inch below the costal arch, where the organ can be indistinctly felt; it is soft, its surface not irregular, and manipulation causes no pain. Nothing corresponding to a distended gall-bladder can be detected. Stomach resonance is obtained as high as the fifth rib in the left anterior axillary line, and the patient complains of flatulence. The tongue is large, coated, and transversely furrowed. The urine is of low specific gravity (1008), and contains bile-pigment, but no albumen. The progress of the case during the following six days was eminently unsatisfactory. She was in almost constant pain, relieved only by morphia administered subcutaneously; she vomited repeatedly, and became more and more pinched and exhausted. The abdomen became tender, and its examination badly tolerated; but on one occasion a mass, judged to be about the size of a pigeon's egg, was felt one inch above and two inches to the right of the umbilicus, and the opinion was hazarded that it might be the gall-bladder containing stones. The bowels were acted upon by purgatives, no gall-stones being present in the motions. An exploratory operation was, after consultation, decided upon, its object and risks having been explained to the patient and her relatives.

The operation was performed by Mr. Pearce Gould on Sept. 15th. Ether was the anæsthetic selected, on account of the supposed cardiac disease, and was administered by Mr. Henry Davis. Full antiseptic precautions were adopted, excepting the spray, solution of bichloride of mercury (1 in 2000) being used for sponges and hands. An incision four inches long was made in the right linea semilunaris and continued down to the peritoneum. Previously to opening the peritoneal cavity all bleeding points in the wound were seized with forci-pressure forceps. On opening the peritoneal cavity the liver was at once seen to be considerably enlarged, with a deep notch in its free border in the position of the gall-bladder, but that organ could neither be seen nor felt; the finger when passed in deeply under the liver felt a stone. The omentum and colon were protected and pressed down by a flat sponge, the edge of the liver gently raised, and a careful dissection was made in the direction of the gall-bladder, which was exposed after dividing firm peritoneal adhesions. The bladder was small, did not reach the free border of the liver, and no stone was felt in it. An aspirator was introduced, and about two drachms of pale bile and mucus withdrawn. The puncture was then enlarged to admit the forefinger, but the stone could not be felt from the interior of the bladder. Repeated attempts to pass a probe into the cystic duct failed, nor could the stone be pushed back into the gall-bladder or into the intestine. It was then found to be quite impracticable to stitch the gall-bladder to the abdominal wound, and it lay so deep that an attempt to suture the wound in it was hardly more successful. Under these circumstances the fundus of the bladder was freed from the liver, and a stout silk ligature was tied tightly around the bladder well beyond the wound, and the part incised cut off. Its wall was found to be considerably thickened. The peritoneum of the stump was then stitched over the mucous membrane with fine catgut. The stone was now felt for again, and it was found to be very movable, at times slipping out of reach, so that it was impossible to grasp it between the fingers or in a forceps, or to force into the duodenum. All hæmorrhage having been stopped and the peritoneal cavity sponged out, the wound was closed with several deep and superficial chromic catgut sutures, and dressed with iodoform wool. The operation lasted a little over two hours.

The case rapidly progressed to a fatal termination. The patient never rallied from the shock of the operation, and complained of intense pain about the wound, relieved only by frequently repeated injections of morphia. Her breathing became laboured, and she presented the physical signs of severe acute general bronchitis with progressive rise of temperature, finally attaining 105° immediately before death, fifty-four hours after the operation.

The necropsy was made by Dr. Pasteur twenty-two hours after death, and showed the following condition:—Rigidity present, integuments deeply bile-stained. On opening the abdominal cavity there was a considerable amount of recent adhesive peritonitis around the edges of the wound, to which the great omentum was adherent. The small omentum was firmly attached to the under surface of the liver, both lobes of which were covered with recent lymph. A short, deep, abnormal vertical fissure, an inch and a half to the left of the falciform ligament, bounded a supernumerary lobe, which probably corresponded to the prominence felt during life. Immediately below the liver, and shut off from the general cavity of the peritoneum by recent adhesions, was an irregular cavity containing some bile-stained fluid, and lying against the liver was the end of the cystic duct surrounded by a ligature. The orifice was not completely closed by the ligature, and easily admitted a medium-sized probe, which passed along the cystic duct a distance of about three-quarters of an inch. There was no evidence of general peritonitis. The liver, stomach, and duodenum were removed *en masse*. The stomach was dilated, but otherwise healthy in appearance. The duodenum was also normal. On compressing the common bile-duct in a downward direction, bile flowed freely into the duodenum. The hepatic and common bile-ducts were enormously dilated, the two forming one straight, cylindrical tube from the liver to within half an inch of the duodenal papilla. Lying in this, and very freely movable in every portion of it, was a single cylindrical stone, 1 in. in length and 1¼ in. in circumference; its lower end squared off abruptly, but above it tapered off in a conical summit much resembling a rifle-bullet. Its weight when dried was 27 grs. The cystic duct was not dilated, and a small probe was now passed with some difficulty from it into the common duct. The portal vein was normal. There were considerable dilatation and hypertrophy of the biliary system throughout the liver, which was unduly tough. The spleen was large and soft; it weighed 9 oz. The kidneys were moderately granular. The heart weighed 10¾ oz.; its cavities contained mixed clot, and were not dilated; there was some fibrotic thickening along the margins of the mitral valve, but no vegetations; the aortic valves appeared normal. There was marked atheroma of the aorta. Both lungs were studded with subpleural hæmorrhages and extensive areas of collapse and broncho-pneumonia. The bronchi contained much frothy mucus.

Remarks by Dr. PRINGLE.—It is obligatory to record in detail all cases of an operation still under discussion, the acceptance of which as a standard surgical procedure must ultimately depend upon the results of extensive collective experience. [Dr. Pringle also refers to the successful results of the operation when performed for distension of the gall-bladder due to impaction of a stone in the cystic duct, not agreeing with an opinion which has been expressed that the occurrence of jaundice during and after the passage of a gall-stone is of extreme rarity.] The case narrated was fully acknowledged not to accord with the type which presents the most favourable conditions for operation, inasmuch as the seat of arrest of the gallstone could not be definitely determined, and the evidence as to distension of the gall-bladder was equivocal. Recorded operative experience upon cases similar in these respects, although admittedly not encouraging, is based upon too small a number of cases to have much value. The patient's constant suffering and rapid downward progress prompted recourse to any measure calculated to afford her the slightest chance of relief. The object of the operation was, in the first instance, exploratory; and after the easy discovery of the gall-stone by the finger it was [illegible]ed that its removal would be satisfactory, at all events, that it might be [illegible]om outside the duct, as

has been twice successfully practised. Unforeseen difficulties were, however, encountered in the numerous adhesions about the gall-bladder, the removal of which organ became a matter of necessity, and in the extreme mobility of the stone, which it was found impossible to fix at the bottom of so deep a wound. The great thickness of the wall of the gall-duct, found at the necropsy, showed the perfect feasibility of the ingenious manœuvre which has been termed "cholelithotrity." Finally, it cannot be doubted that death was in great measure, if not mainly, due to the lung condition resulting from the administration of ether as the anæsthetic selected, on account of an erroneous intepretation of the cardiac physical signs; and it is hoped that the publication of this fatal case may not deter surgeons from operating upon similar cases, whilst it may forewarn them of some of the difficulties which may have to be encountered.

LIVERPOOL NORTHERN HOSPITAL.

SYNOVIAL CYSTS IN CONNEXION WITH THE KNEE; SYNOVIAL CYST OF THE WRIST; OPERATIONS; RECOVERY; REMARKS.

(Under the care of Mr. CHAUNCY PUZEY.)

CASE 1. *Synovial Cyst in the Calf of the Leg, communicating with the Knee-joint; Synovial Cyst of the Wrist; Operations; Satisfactory result.*—T. W——, aged twenty-four, a printer, was admitted on Feb. 17th, 1885. He said that he had rheumatic fever four years before, that the right wrist-joint and knee-joint were most affected, and that the swelling never quite disappeared from the wrist. A month before admission, after a slight contusion or squeeze of this wrist, an increase of swelling appeared as below described. The man's own expression (as noted by Mr. Horrocks, house-surgeon) was that "it seemed to drive it to both ends."

On admission, there was a rounded, elongated swelling over the radial side of the back of the wrist and hand, extending from the base of the first metacarpal bone to about two inches above the wrist-joint. There was no redness or heat about the swelling, which was divided into two portions by the annular ligament. Fluctuation existed between these two portions, and a sort of soft crepitus was felt occasionally on squeezing the contents from one portion to the other, as if caused by the passage of loose bodies. The man's right knee presented an interesting condition. The joint was considerably distended with fluid, and there was a large fluid swelling in the upper part of the calf of the leg, evidently communicating with the joint. This was diagnosed as an enormously distended bursal swelling or synovial cyst, communicating with the knee-joint, and it was decided to test the man's capability of tolerating operative measures by attempting a radical cure of the wrist before in any way interfering with the knee.

On Feb. 18th, under full Listerian precautions, the tumour in the wrist was freely opened by two incisions, one above and the other below the constricting annular ligament. A considerable quantity of thick synovial fluid escaped, and with it two or three "melon-seed bodies," and two more, which were still attached to the wall of the cavity, were removed by scissors. No tendon appeared. The cyst wall was stitched to the skin by three or four sutures, and the track was syringed through with a solution of carbolic acid and iodine. The usual dressings were applied, and the limb fixed on a splint. No complications arose. The wounds healed by granulation, and on March 4th the patient left the hospital with his hand in the most satisfactory condition. He had been kept in bed most of the time, with the knee-joint fixed in a splint, the result being that the swelling in that part had considerably diminished; and he was advised to go to his home near Manchester, and after resting for a while to try if he could resume work.

On May 4th the man returned to the hospital with the determination to submit to the risk of operation, for he said he could never depend upon his knee not giving way under him, causing him to stumble and fall, whereas his wrist, which before operation had been getting weaker and weaker, was now quite strong and useful. The swelling of the knee-joint, he told us, had existed for four years; but it was about a year later that he noticed a swelling behind the knee, which appeared suddenly and [illegible] suddenly with some diminution of the swelling [illegible] joint. The size of the sw[illegible] amount of walking undergone, but on the whole there had been a gradual increase of the swelling in the calf.

The condition on admission (as noted by Mr. Horrocks) was as follows:—The affected knee measures 14½ in. round the joint above the patella, and 14 in. below it; the sound knee measures 12¼ in. round the joint above the patella, and 12¼ in. below it. The fulness over the front of the affected thigh extends 3 in. above the upper border of the patella, and laterally is more marked on the inner than the outer aspect of the joint; the depressions on each side of the ligamentum patellæ are distinct, but the patella floats. Fluctuation is distinctly felt between the joint and the swelling in the calf, and *vice versâ*. On examining the back of the leg, a transverse oval swelling 4 in. across and 2½ in. from above downwards is seen in the upper part of the calf; above this there is a transverse depression, and higher again than this a smaller and more deeply situated oval swelling, and fluctuation can be obtained between this and the other swellings. The calf of the affected limb measures 13¾ in. in circumference at the most prominent part of the swelling, the measurement at the corresponding part of the sound limb being 11¾ in.

After a few days' rest in bed, on May 10th, under carbolic spray, the swelling in the calf was laid open freely, and about five or six ounces of thick synovial fluid were evacuated. (Before commencing the operation the knee-joint was firmly bandaged with a Martin's rubber bandage, so as to force the fluid from the joint into the calf, and to prevent the admission of air into the joint.) The sac wall was found to be very thin everywhere, except at its upper part, where it was constricted, and communicated by a narrow channel with the upper and more deeply situated sac; here the cyst wall was thick and wrinkled, looking like the mouth of a bag where it is tied. Through this narrow opening a director was pushed, and the opening was enlarged with a bistoury sufficiently to let out a small quantity of fluid and to permit exploration with the finger. The walls of this smaller cavity were thicker and rigid. The communication with the joint was not found; it was probably too sinuous. As much as possible of the walls of the lower and thinner sac were torn or dissected away; a large drainage-tube was fixed in the upper one. The lower half of the wound was stitched up; the upper half was freely swabbed with tincture of iodine. The limb was fixed on a modified Thomas's knee-splint, and the wound dressed with iodoform wool and Listerian dressings. Then the Martin's bandage was removed from the knee.

May 11th.—Dressings changed (under the spray); found fairly soaked with thin, synovia-like fluid, slightly blood-stained; no effusion in the joint.

15th.—Since the last note the patient has continued to do well; the lower part of the wound has healed. The large drainage-tube was removed to-day, and a smaller one substituted.

30th.—Wound nearly healed. Drainage-tube shortened.

June 13th.—Drainage-tube removed some days ago. Small superficial wound remaining.

By the end of the month the wound was quite healed, and a day or two later the man was allowed to get up. On July 24th he went home. The condition of the limb was most satisfactory; there was no swelling of the joint, and the slight stiffness resulting from the enforced fixing of the limb had almost passed away. At no period of the operation was there the slightest cause for any anxiety. Some months afterwards the man called at the hospital and reported himself to the house-surgeon as being quite well, and engaged at his ordinary work.

CASE 2. *Synovial Cyst in Popliteal Region; Operation; Successful result.*—J. K——, aged fifty-one, a commercial traveller, was admitted on March 3rd, 1885. He complained of weakness of the left knee. On examination a swelling of the size of a small Tangerine orange was found in the lower part of the popliteal space, slightly to the inner side of the median line. It did not pulsate; when the knee was flexed it disappeared, and on extension of the leg it stood out prominently and felt very tense. There was no redness or tenderness about it.

The limb was fixed on a Thomas's splint, and a succession of blisters over the swelling was tried; but as this seemed to have no marked effect, and as the patient became importunate for more active treatment, operation was decided upon. On April 30th the swelling was laid open thoroughly, under carbolic spray, and about [illegible]ance of thin "calves'-foot jelly"-like material escaped.

The sac, which was very thin, was found to dip down between the heads of the gastrocnemius, and a probe was passed upwards some distance in the direction of the joint, with which, however, no communication could be proved. As much of the cyst wall as possible was stripped away, and a drainage-tube fixed in the deep part of the wound. The superficial part of the wound was stitched up, the iodoform wool and gauze dressings applied, and the limb fixed on a Thomas's splint. All went on well. On May 9th the drainage-tube was shortened, and a week later was removed altogether. By June 3rd the whole wound was soundly healed, and the man was walking about. He said that his knee felt rather stiff (probably from its long-continued position of full extension), but it was seen that he could freely flex it to a right angle. On June 7th the man went out well, and ready for work.

Remarks by Mr. PUZEY.—Of these two cases, in the latter there is some room for doubt as to whether any communication existed between the cyst and the joint; but the former was manifestly one of those to which Mr. Morrant Baker has specially drawn attention in the thirteenth and twenty-first volumes of St. Bartholomew's Hospital Reports, and it appears to me worth recording, because it illustrates many of the conclusions at which he arrived, and it shows how such cases may be treated without running much risk of the calamities which appear to have generally resulted from operative interference. In the case of T. W——, we have the history of two joints—the wrist and the knee—suffering severely from an attack of rheumatism, and never completely recovering from it. Then cystic swellings appear—in the case of the knee obviously, in the case of the wrist most probably, in connexion with the joint. An inspection of the interior of the popliteal swelling showed that it had originated at the back of the joint, and that later on this primary synovial cyst had forced an opening for itself apparently beneath the lower border of the popliteus, and then rapidly the secondary tumour had been formed, as shown by the thinness of the sac wall in every part except at its neck, where the walls of the canal were thick and corrugated, like the neck of a bag. Whether the primary cyst had originally been a bursa which communicated with the joint, or whether it was a true hernia of the synovial membrane, I cannot of course say; and from a surgical point of view it is not of much importance, although of interest pathologically. As may be seen by reference to the articles above referred to (especially pp. 258-261 of vol. xiii. of St. Bartholomew's Hospital Reports), post-mortem examination has not yet thrown much light on this point. But the very important practical question is—How should such cases be treated? The answer given by most authorities amounts to a strong recommendation to avoid any operative interference, and this seems justified by the many cases recorded (and how many more have probably been unrecorded?) in which loss of limb or life has resulted from such interference. But I think it will be found that in the majority of these cases the true nature of the affection has not been recognised in time, and due precautions have therefore not been taken. Several years ago I saw a young woman with a large fluid swelling in the upper part of the calf of one leg. I proposed to admit her into hospital, intending to operate antiseptically. I saw no more of her, but heard, some months after, that another surgeon had opened the swelling at her own home, and that she died in a few weeks. I was unable to ascertain particulars, but have no doubt as to what the nature of the swelling was, and very little as to the sequence of events. But surely antiseptic surgery gives us a freer hand; and although, perhaps, in the case of the well-to-do patient palliative treatment may answer all purposes, in that of the working-man we are justified in risking a little (after duly cautioning him) in view of obtaining a permanent cure. And as Professor Lister has shown us how the knee-joint itself will bear a clean-cut wound, so surely we may venture on a clean-cut wound and on antiseptic drainage of cavities connected with the joint. Paracentesis of such cysts can only be palliative; iodine and such-like injections would be destructive in their effects; and free drainage seems to me to be the only trustworthy means of permanently obliterating the cavity. The extreme tenuity of the cyst wall itself in these two cases leads me to think that it might be possible to bring about this result by forcibly pressing (with the palms of one or both hands) on the tumour, in such a manner as to force the fluid downwards against the weakest part of the sac wall, which might thus be forced through and the contents extravasated into the cellular tissue, thus avoiding any skin wound; and then, by well-arranged pressure and bandaging, absorption of the fluid might take place. Or by means of a long tenotomy knife, made to enter the sac at a long distance from the puncture in the skin, the sac wall might be freely opened and the same object gained. But where the Listerian method can be properly carried out I certainly should prefer the precision and thoroughness of open antiseptic drainage. With regard to the permanency of the cure in these two cases the question remains open, but I believe that if either of these men had had a return of his trouble he would have found his way back to me.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Tumours of the Bladder.—Supra-pubic Cystotomy.—Fracture of the Head of the Radius complicated by Fracture of the Coronoid.

AN ordinary meeting of this Society was held on the 26th ult., Mr. Thomas Bryant, F.R.C.S., President, in the chair. Nearly the whole of the evening was occupied with the surgery of vesical tumours.

Sir H. THOMPSON contributed a paper on Tumours of the Bladder, in which he gave a brief sketch of six cases in which he operated during the last twelve months, showing the parts removed in each case. In three the supra-pubic operation was employed; in two the perineal incision only: and in one, that of a female, urethral dilatation was sufficient for the purpose. It may be added here that in two cases the result is without doubt a complete and permanent cure. In two others the disease, although known to be considerable, was more so than might have been expected from the preliminary examination, and death, in each case imminent, was in one certainly, perhaps in both, postponed for a short time. In each the operation was undertaken only with the view of palliating the patient's condition, not of saving him; removal of the growth, so far as this was possible, being the only mode of arresting severe and continuous hæmorrhage. The remaining two cases are of recent date, and it is only possible to say that the patients have thus far progressed satisfactorily.

Mr. BERNARD PITTS read a case of Supra-pubic Cystotomy two years after the removal of growth by perineal operation. The patient was a man aged forty-five. He began to have hæmorrhage from the bladder about three years before the first operation, or five years ago. When he first came under observation he was losing a large quantity of blood, his urine was very offensive, he was cachectic, and unable to follow his occupation. After operation and removal through the perineum of a pedunculated papilloma he regained his health, his urine became clear, and he saw no trace of blood in it for a year and a half. When examined in July last he was in good general health and actively engaged in his occupation as a watchmaker, but he had a constant deposit of blood and mucus in his urine, and was occasionally passing small clots; micturition was frequent and attended with some pain. In spite of treatment these symptoms continued, and on September 22nd a supra-pubic exploration was made, and it was found that at the site of the old pedicle—viz. just below the right ureter—there was a widely diffused recurrence; the growth was for the most part but slightly elevated, but there were several cone-like elevations of the size of the top of one's finger. These projecting buds were nipped off with forceps, and the broad base of the growth was scraped with a sharp spoon. A number of small sessile tufts were seen on the sides and base of the bladder, and were, as far as possible, removed with the spoon. The patient made a good recovery, and exactly one month after operation the bladder opening had entirely closed. He had lost all trace of blood in his urine, and all pain. The portions of growth removed were firm, and quite different in naked-eye appearance to what was removed on the first occasion. Microscopical examination showed the recurrent growth to be papilloma, presenting, however, [illegible] character. The conclusion of [illegible] future of the case, since

it was very likely that further operative interference would in time be necessary, and it was suggested that one should not be in a hurry to interfere in such a case because of slight return of symptoms, but that it would be better to wait until the patient was rendered unfit by hæmorrhage or exhaustion to follow his occupation; then to again open his bladder above the pubes, and to remove the growth as freely as possible, and if on examination the growth presented no further evidence of a malignant change to be content with this; but in case there was distinct evidence of change in the character of the growth, or if the growth was so luxuriant that successive operations failed to keep it in subjection, then it would seem right to give him a chance of prolonged life by diverting the ureters, and subsequently removing such parts of the bladder as necessity compelled. It was suggested that by an incision in the groin, as for ligature of the external iliac, the ureter might be reached, and ligated near the bladder, and the fore-end then brought to the surface; that after the wound had healed, and the kidney was accustomed to the change, the same operation should be done on the opposite side. The bladder would then be rendered a passive organ, and the growth within it could be dealt with through the supra-pubic opening, either by application of caustics or by stripping back the peritoneum as far as the attachment of the ureters, and then removing the greater part of the bladder, taking away the mucous coat from such part as from the connexions it might be inadvisable to otherwise meddle with.—Mr. JOHN CROFT related a case of flat epitheliomatous growth situate behind the trigone; the tumour could not be removed, but great relief followed the establishment of the perineal fistula, which was allowed to remain open for nine months, when the growth grew through the perineal wound; the hæmorrhage and dysuria ceased from the time of the perineal exploration. Another case occurred in a lady; it was a fimbriated growth. The urethra was dilated, and the whole growth was scraped away in fragments by the aid of the finger-nail. The hæmaturia had ceased, and had not returned, now four months since the operation.—Mr. THOMAS BRYANT felt that this operation was a great advance; but the founders of the Society would have regarded it as a rash innovation. Most of the cases were of the "rescued" kind. The average duration of life in tumour of the bladder would be an interesting item of information. He had operated on twelve cases, and all by the perineal section. One case ended fatally, probably because the supra-pubic method had not been employed. But perineal exploration ought first to be used. For the actual operation the supra-pubic method was probably to be preferred in most cases of extensive growth and near the fundus. If the tumour be small and situate at the base, the perineal section might be best for the removal of it. He gave illustrations of the principle that small tumours could produce severe symptoms. The case of a female child suffering from profuse hæmaturia was narrated, in which on withdrawing forcibly a sounding catheter the eyelet contained a papilloma which was torn away from the mucous membrane of the bladder. The child did well, and was healthy sixteen years later. In the case of a lady suffering from vesical spasm and hæmaturia, a small growth not larger than a haricot bean was found near the neck of the bladder; the tumour was easily removed and was a fimbriated papilloma. Eighteen months ago a man with vesical hæmorrhage was reduced to the last degree of anæmia; the bladder was explored through the perineum; the whole bladder appeared to be filled with villous growth. Sir Henry Thompson's forceps were used, and a great deal of the growth was removed; the bladder was scraped throughout, the walls being wiped rather roughly with a sponge on a holder. The man steadily recovered, and remained well for six months, when slight hæmaturia persisted for a week, but this never recurred. Another case of a calamitous kind occurred in a man in whose bladder a fibrous polypoid growth sprang from the fundus; this was seized and withdrawn. A second one was detected, but was not so easily removed; it was drawn into the perineal wound and snipped off. The man died of peritonitis, and a small hole was found in the bladder at the site of the removed polypus.—Mr. HENRY MORRIS had operated in five or six cases. The perineal section was performed in all. Of these only two were thought to justify further op[illegible] that had been one of vesical calcul[illegible] covered, and removed w[illegible] two days later—as the tumour was unexpected at the time of the perineal exploration. In another case, that of a large hard tumour with nodulated surface, the size of a small orange it was found impossible to remove it through the perineal wound, and a supra-pubic opening was made. The two wounds were a great advantage in this operation; but it was impossible to remove the whole of the disease. Though the rectal bag was much inflated, it was surprising to find how little the bladder had been elevated, for a fold of peritonem still presented in making the parietal incision. The tumour extended from the ureter on one side up to the fundus on the same side. Would it be more advantageous to close the perineal or the supra-pubic wound for the purposes of drainage? He did not think that the suggestion made by Mr. Pitts was too adventurous. Draining the kidneys by turning the ureters away, and make urinary fistulæ either in the loin or groin, was scientific treatment on a par with the operation of lumbar colotomy for rectal obstruction. The little inconvenience of urinary fistulæ was illustrated by two cases.—Sir HENRY THOMPSON said that washing out by the catheter was not a certain method of diagnosis. The lithotrite might remove fragments suitable for diagnosis, but this should be done cautiously. He could not certainly diagnose a tumour in the bladder by means of the sound, as the papillomata were very soft and light; even with the finger in the rectum a certain diagnosis was not possible. The perineal opening was no disadvantage whatever, and should form the exploratory opening. He advised in his first paper that the surgeon should lay hold of nothing whilst the assistant is pressing down from the outside, lest the peritoneum be wounded. Had he been aware of what could be done by the supra-pubic method at that time he would not have used the perineal method for that case. Drainage afterwards through the supra-pubic wound was quite sufficient. He referred to the case of a man with very large prostatic growth, necessitating frequent catheterism and causing much exhaustion. A supra-pubic opening was made and a curved silver tube introduced; it was a perfect drain, and the patient still had a permanent opening and enjoyed existence. The urine drains away into a urinal which the patient wears. The suggestion by Mr. Pitts was a novelty well worth consideration. He was thankful for a suggestion thrown out by the President, that a new sponge tightly tied round a forceps was a method of clearing out an extensive villous growth.—Mr. PITTS said that he had perhaps prematurely come to the opinion that the supra-pubic operation was the best. There might be some cases that could be better treated by the perineal method.

Mr. B. WAINEWRIGHT read a paper on Vertical Fracture of the Head of the Right Radius and Fracture of the Coronoid Process of the Ulna, caused by a fall on the hand, in a man, a rivetter by trade, producing great restriction of all the movements of the forearm and inability to follow his occupation. It was treated by excision of the head of the radius and removal of the fractured portion of the coronoid process of the ulna, resulting in greatly improved mobility of the forearm, and enabling him to resume his work.

After Mr. Butlin had exhibited a screen of drawings of Diseases of the Tongue the following living specimens were shown:—Dr. James Anderson: Intracranial Murmur with relapsing Optic Neuritis. Mr. Mansell Moullin: Complete cure of Gunshot Wound of the Foot. Dr. Beevor: Cases showing type of Paralysis resulting from pressure on fifth and sixth cervical roots. Dr. Hale White: Addison's Disease with Leucoplacia Buccalis.

MEDICAL SOCIETY OF LONDON.

Athetosis.—Congenital Dislocation of Patellæ.—Pes Gigas.—Erasion of Diseased Joints.—Dermatitis Herpetiformis.—Cystitis treated by Electricity.

A CLINICAL meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Dr. C. E. BEEVOR showed a case of Athetosis in a man aged twenty. There was a history of a convulsive fit at the age of thirteen, and loss of power on both sides. He gradually recovered power in the left side, but remained paralysed in the right leg and arm. Ever since the seizure he had [illegible] from epileptic fits, occurring about once a year.

The movements commenced in the right arm and hand only a year ago. Voluntary efforts increased the movements. The right hip-joint was dislocated—it was said as the result of the first fit. The right limbs were much shorter than the left. There was but little difference between the two sides of the face. The movements ceased during sleep. There is no mental defect, though his aspect and speech might suggest this. He has never been aphasic. Dr. Beevor considered that there was a cerebral lesion, but did not attempt to localise the lesion more precisely. Voluntary movements were possible with the right hand, though much interfered with by the involuntary athetosis.

Mr. HERBERT ALLINGHAM showed two cases of Congenital Dislocation of Patellæ; the quadriceps muscle was atrophied. The vastus internus in the boy shown did not respond to electrical reaction.—Mr. J. H. MORGAN was disposed to think that laxity of the internal lateral ligament was the chief cause of the displacement.—Mr. NOBLE SMITH had seen two cases.—Mr. F. B. JESSETT had met with one case.—Mr. W. H. BENNETT considered that infantile paralysis might lead to the dislocation, as he had seen in one case.—Mr. EDMUND OWEN thought that knock-knee might be a cause, in addition to congenital malformation and to infantile palsy.

Mr. H. ALLINGHAM showed a remarkable case of Pes Gigas. The hypertrophy appeared to affect only the anterior part of the foot, and involved the cellular tissue chiefly. The bones did not appear to be enlarged. There was no evidence of neuroid tissue in the hypertrophy, which probably involved the lymphatic and connective tissues.—Mr. DAVIES-COLLEY had recorded a somewhat similar case in the Pathological Transactions three years ago. The foot was amputated through the metatarsal bones. Billroth had pictured such cases in his Clinical Surgery.—Mr. W. H. BENNETT had treated a case of the kind by partial amputation, with very good result. There was some tissue that resembled myxoma.

Mr. EDMUND OWEN showed two cases of Chronic Suppurative Knee-joint Disease, treated by free removal of the diseased tissues. A flap was raised from the front of the joint, in which the patella was contained. The semilunar fibro-cartilages were removed, and the whole cavity rendered aseptic by injections and washings of corrosive sublimate. No local or constitutional disturbance followed the operation. There was ankylosis in each, and no shortening of the limbs.—Mr. F. B. JESSETT fully concurred in the treatment, which was less liable to be followed by severe accidents than resection, and it left no shortening.—Mr. DAVIES-COLLEY'S experience of erasion of the knee-joint was not so favourable. In children he would prefer excision; the epiphysial lines need not always be interfered with.—Mr. BRUCE CLARKE had used the method in a boy in whom the disease was more chronic. A movable joint might be secured if the disease were treated early. A movable was preferable to an ankylosed joint.—Mr. W. H. BENNETT asked whether it should not be the aim of the surgeon to obtain a movable joint.—Mr. BENTON considered that bony ankylosis would not result; there was already some movement.

Dr. STEPHEN MACKENZIE showed a case of Dermatitis Herpetiformis in a man aged thirty-nine. He had a chancre at the age of twenty, but no secondaries. He had had no skin affection till last Boxing Day, when he drank freely and slept in a damp bed. Catarrhal symptoms followed. On Jan. 5th a vesicular eruption appeared on the face and neck. Some bullæ also came out on the arms, as well as erythema on the chest and arms. Where the erythema was there were no vesicles. Ever since January he had had the condition of hyperæmia, vesicles, and bullæ of variable severity. The erythema marginatum was very fugacious, but generally permanent. Duhring had described these cases as dermatitis herpetiformis. He drew attention to the multiplicity of the lesions. Erythema, vesicles, bullæ, and pustules were generally present in the same cases concurrently or consecutively, associated with small vesicles arranged in groups. In all the cases Duhring described (sixteen in number) there was much itching—whence the term pemphigus pruriginosus; but there was no pruritus in Mr. Mackenzie's case. Certainly, as Duhring stated, herpes gestationis was a variety of the same disease. A coloured drawing of a case of this kind in a pregnant woman was shown. Some of the cases described by Bazin and Tilbury Fox as hydroa were of the same nature. Impetigo herpetiformis of Hebra was always fatal, and probably not the same affection as dermatitis herpetiformis. The disease was very rebellious to treatment, but arsenic seemed to have some influence over it. Cold appeared to increase its severity. One case of Duhring's had lasted sixteen years. In reply to questions from Dr. Veale and Dr. C. T. Williams, he said there was no albuminuria and no glycosuria, and the reaction of the urine was natural.

Mr. BRUCE CLARKE showed a case of Cystitis, which was apparently benefited as the result of the application of the constant current for ten to twenty minutes once or more times a week. Benzoate of soda was given in large doses, and every other treatment carried out, including cystotomy.—Mr. E. OWEN considered that cystotomy would cure most cases of cystitis.—Dr. S. MACKENZIE asked whether salicylate of soda in large doses had been given.—Mr. SWINFORD EDWARDS asked whether the negative or the positive pole was introduced into the bladder, and whether the walls of this viscus were touched.—Dr. C. T. WILLIAMS asked how the electricity acted.—Mr. BRUCE CLARKE said he could give no satisfactory explanation.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

A Review of the Past Year, with some Reminiscences of Cholera and Tropical Fevers.

A MEETING of this Society was held on Wednesday, Nov. 10th, Dr. Walter Dickson, R.N., President, in the chair.

Dr. DICKSON, after thanking the Society for the honour of re-election, and congratulating it on its present flourishing condition and the work done last session, paid fitting tribute to the memory and scientific labours of the distinguished members whose loss they had to deplore during the past year—Dr. G. Milroy, Dr. T. S. Cobbold, and Dr. Varentrapp of Frankfort,—all of whom had for many years been connected with the Society. Dr. Dickson then proceeded to consider the epidemic of cholera which, beginning at Brindisi and Venice in the spring of this year, inflicted serious loss in several provinces of Italy, chiefly on the Adriatic Coast, and in the valley of the Po, but also extended to a few places on the west coast near Naples, and to Cagliari in the island of Sardinia. It subsequently spread to Istria and Hungary, but on the whole was much less destructive than former epidemics, the larger cities of Italy having escaped. A minor outbreak in the extreme corner of Brittany in the winter months reminded us that these visitations were not always associated with high temperature, and the report to the French Minister of Commerce showed conclusively how the disease spread from individual to individual, and village to village, in a group of small fishing ports in the department of Finisterre. The highest mortality was always coincident with the most defective sanitation, and in Audierne, with 1700 inhabitants, 400 cases occurred, and 144 deaths. Drunkards, and those who, while nursing the sick, took their meals in the bed-chamber, were especially observed to suffer. Although distinctly traced from one small town to another, its first appearance was variously ascribed to importation from a distance—from Brest or from Toulon, through sailors who had returned from Tonquin, or, as suggested by the Medical Commission of Inquiry, through fishermen returning from the coast of Spain, which was last year devastated by cholera. The troops stationed in the district did not suffer, their better hygienic condition protecting them from the disease. In Italy cholera is always regarded as introduced from without, and quarantine regulations are more confided in than sanitary precautions, involving trouble and expense. The relaxation of the old restrictions was deeply resented by the people, and the Government, though disposed to tread in the paths of this country in the matter of local sanitation, had to yield in some points to popular clamour. Some advance, therefore, has been made by the adoption of the five days' detention of ships and the abolition of land quarantine by the International Conference at Rome last year. In time, no doubt, the English idea of scrupulous universal cleanliness, as the best preventive of cholera and all other epidemic diseases, will obtain extended acceptance among the southern nations of Europe, which have recently so grievously suffered from their neglect of it. Dr. Buchanan's admirable summary of the argument was quoted, and the Local Government Board for [illegible] correct sanitary defects

wherever they were reasonably suspected to exist. Dr. Koch's researches on cholera microbes and M. Pasteur's prophylactic inoculation for hydrophobia were to be regarded as valuable advances in epidemiological science, though still on their trial and requiring corroboration from further experience. Reference was made to the Peruvian verruga and the recent deplorable self-sacrifice of a young physician of Lima, who inoculated himself with the blood of a patient ill with the disease. After a period of incubation of twenty-three days he induced the disease, and died on the thirty-eighth day, showing that the malady, though strictly endemic, confined to a limited tract of country, and not necessarily contagious, is zymotic and inoculable, and possibly dependent on a bacillus, reported to have been discovered by Professor Izquierdo of Chili, circulating in the blood and provoking the local changes that mark the disease. In the last report of the health of the Royal Navy were found some interesting details of the etiology of the fevers which occurred to the force in the Soudan, Egypt, and Malta in the recent war, and which greatly raised the rate of sickness and mortality. On the west coast of Africa the cases of paroxysmal fevers of the climate appeared to have been of a mild type, although very numerous. In one vessel in the Niger, with seventy whites, all except six were affected by malarious fever, yet no death or invaliding had occurred. Only one case of yellow fever is recorded in the whole naval force (at Callao, in the Pacific), in a man who had slept on shore. Only five cases of cholera seem to have occurred in the whole force (all at Amoy, in China), and were traced to the free use of aerated water manufactured in the town from water polluted with sewage. The naval statistics show a portentous increase of venereal affections, chiefly on the home station. In the whole force absence from duty from this cause has amounted in the year to five days per man—a loss of time equal to that caused by all the zymotic, rheumatic, respiratory, and digestive diseases put together. On some foreign stations there had been a diminution of venereal disease in the navy owing to the salutary regulations enforced by the local authorities; and at the Cape of Good Hope a frightful extension of syphilis, affecting a large portion of the population, including many infants and young children, had led to a great change in public opinion; and the restrictive measures, which had been some years ago repealed by the colonial Legislature, have been again introduced, as absolutely necessary to avert further evil. The President then gave some of his own experiences in the navy in regard to cholera and kindred disorders in two instances, which, in the microcosm of a ship and the thorough knowledge of the persons affected, afforded good opportunity of studying etiology. In the first, a corvette with 200 men serving on the Baltic coast in the first year of the Russian war, the sanitary condition of the ship and crew were very defective, and much deteriorated by the arduous work of incessant cruising in cold, damp, tempestuous weather, blockading the enemy's ports and destroying his commerce. In the end of September, 1854, she captured several prizes, which were sent in care of seventy men into Memel, which had that summer been visited by cholera. A heavy gale drove the ship off the land and prevented communication with the prize crews for four days, during which they underwent much hardship and privation. When they returned on board, nearly all were found to be suffering from bowel-flux in various degrees of intensity, and two died of cholera—one in fifteen hours, the other with consecutive fever on the ninth day. A third case, in a man who had not been on shore, and was less severe, survived to the tenth day, and, in the final stage, had black vomit as well as rice-water evacuations. The men who had not been on shore were affected in far less proportion than those who had been with the prizes at Memel, of whom more than one-third suffered severely, and few of them escaped the minor form of the disease. The other example was of a frigate with 500 men, the flagship on the East India station, which, during eighteen months' service in India, Ceylon, and Arabia, had enjoyed a marvellous immunity from disease, and was in perfect hygienic condition when she arrived at Aden in March, 1859, after lying six months off Jeddah in the Red Sea. Leave to go on shore was given, Aden at that time being reputed healthy, although it was afterwards discovered that a few sporadic cases were occurring among the natives. A few cases of bowel complaints were found when they [illegible] board, and in three decided cholera was [illegible] The ship at once put [illegible] internal economy, although several cases of diarrhœa occurred in the next few days, none attained choleraic intensity. Both instances show that in the cold bleak climate of Prussia, as well as in the intense dry heat of Arabia, much risk is run by communicating with cholera-stricken localities. Malarious fever was then discussed as it appeared on board a steam-sloop with 110 men, employed for three years (1850 to 1853) on the west coast of Africa in the suppression of the slave-trade. Minor forms of fever were not uncommon, but in the River Congo, where the vessel lay seven months, from one to [illegible] miles from the shore, it was found that while those who remained on board her scarcely suffered, the crews of the boats, which often ascended the river forty miles to search for slavers and lay near the banks, were much affected by terrestrial miasms, and a considerable portion, one-third of those so employed, contracted malarious fever. Some, who were natives of ague districts or had formerly had that disease, showed only the quotidian or tertian type of intermittent, but the majority were severe cases of remittent, with an average period of twelve days' incubation, exhibiting high pyrexia during the first week with only slight remissions, critical evacuations from the fourth to the seventh day of perspiration, or urine, or blood from the mucous membranes, and, although all recovered, their convalescence was exceedingly slow, with occasional relapses. Only one death occurred in a young officer, who had not been exposed in the boats, but was a man of intemperate habits, and died on the fourth day with black vomit and deeply jaundiced. Thus, from the same malarious poison in the Congo, arose in a few months the morbid processes of ague, remittent and yellow fever, due, it would seem, to the modifying influences of exposure, natural proclivity, and personal habits of the individuals. But two-thirds even of the boats' crews escaped unscathed, and those who remained on board the ship were nearly exempt. Only that one death from disease, and very the little invaliding, occurred during the whole commission of the ship, which was in perfect order, and the greatest care was taken by the commanding officers to mitigate as far as possible depression and discomfort inseparable from three years' sojourn on that dreary station. The last instance adduced by the President was that of a corvette with two hundred men, which lay in the river San Juan de Nicaragua, in Central America, and suffered from the malarious fever of the locality. This ship was in good sanitary condition, and the men had recently come from Europe. It was the hot rainy season, and 16 per cent. of the crew were laid up in nine weeks by various forms of malarious fever one-half of the number sick showing the intermittent, the other half the remittent type. The disease here differed much from that observed in the river Congo and in Africa generally. Pyrexia, at the outset exceedingly high, was moderated in a few hours, persisted with remissions for one or two weeks, after which the patient rapidly recovered without the extreme debility and prolonged convalescence of African fever. One death only occurred, and that by a coincidence was also in the case of a young officer, intemperate in alcohol, who had been, moreover, on shore, and exposed to chill in heavy rain when overheated. Four days after he was seized with fever of the same character as the others; but on the third day he became delirious, with yellowness of the skin and black vomit, and so died, the fatal symptoms being probably induced or aggravated by chronic alcoholism. Bilious discolouration of the skin, of such grave import in tropical fevers, is of less moment in European epidemics. An outbreak of jaundice two winters ago at Bremen, in North Germany, was described as remarkable from its prevalence exclusively among men, its limitation in locality, its being non-febrile and non-fatal, and from its alleged connexion with revaccination, many of the jaundiced having been revaccinated a few months before. Catarrhal icterus has been lately ascribed to ptomaines absorbed from the alimentary canal acting on the liver. Some remarkable epidemics of jaundice had been quoted by the late Dr. Murchison, two of the last being that at Pavia, in Italy, and Rotherham, in Yorkshire, both of great severity. The light recently shed on several zymotic diseases affecting children by the observations of Drs. Ballard, Power, Cameron, Klein, and others, tracing such diseases to morbidly poisonous milk, is one of the chief medical events of the year. Those researches and the others undertaken in regard to the microbes suspected or proved to form an essential part of [illegible] various morbid processes will afford interesting material for [illegible] discussion in the Society.

ACADEMY OF MEDICINE IN IRELAND.

Liver with two Gall-bladders.—Perforation of Stomach.—Colloid Carcinoma of Stomach.—Fibroma of Cornea.

AT the opening meeting of the Pathological Section on Nov. 5th, the PRESIDENT delivered an introductory address.

Dr. PURSER exhibited a Liver with two Gall-bladders. The specimen was of some little interest from its rarity, though not exemplifying any great morphological law. It was taken from a girl aged eleven years, who was admitted into Sir Patrick Dun's Hospital extremely ill of scarlatina, which she had had for five days, and who died a few hours after her admission.

Dr. QUINLAN submitted a case of Perforation of the Stomach. On the 11th of October, at the request of Dr. Franks, he received into St. Vincent's Hospital a patient who was cook to a gentleman. She had been for many years subject to chronic disease of the stomach, with dyspepsia and constipation; and on the Wednesday before her death she took a very large dose of Epsom salts and senna. This dose had a very active effect, and was followed by great pain, which increased day by day, until, on the Friday night, it became unendurable. In her agony she crawled out of bed and knocked at the door of the head of the family, who with great humanity immediately sent for Dr. Franks. The latter, at half-past two o'clock in the morning, found the woman lying on her face, supported on her elbows and knees, and in very great agony. He found that the pain was localised to the left side of the epigastric region. There was no flatulent distension or pain on pressure. Her pulse was 110, and her temperature normal. Perceiving that it was a case of peritonitis, he applied morphia to keep down the pain. She got worse, and on the following Monday was received into St. Vincent's Hospital. Her abdomen was then greatly distended, but it was remarkable that pressure did not increase the pain. He (Dr. Quinlan) saw her immediately afterwards. She was in great agony; her temperature was 101·6°, her pulse 120, and her face had a pinched, collapsed look. He saw that the case would be fatal, and could only endeavour to relieve the pain by morphia. At 11.30 the house-surgeon found her free from pain and speaking calmly, and then she suddenly collapsed and died in a few minutes. On the following morning a post-mortem was made. Irrespective of the particular lesion, she was a healthy, well-nourished woman, her age being thirty-eight. The intestines were greatly distended with flatus, the contents of the stomach were effused into the peritoneum, and there had been very severe peritonitis. There was a perforation in the stomach at the middle of the lesser curvature. The coats of the stomach were red; and there were a number of patches of very severe congestion, looking like the effect of some irritant poison. He examined the grumous fluid in the stomach, but found no trace of antimony, arsenic, or any other poison. There was great thickening of the stomach throughout its entire contents, and considerable evidence of chronic disease. It was evident that the perforation and subsequent peritonitis had been produced by the action of the violent purgative.

Dr. KENDAL FRANKS exhibited the stomach, omentum, transverse colon, pancreas, and spleen of a man who died in the Adelaide Hospital of Colloid Carcinoma of the Stomach. He was only thirty-eight years of age. The history of the disease dated back eight months, when some pain in the epigastrium was first observed. A tumour was felt for the first time two months previously. Abdominal section was performed on Oct. 12th, but as it was evident that the tumour could not be removed the wound was closed. The patient died twelve days afterwards from exhausting diarrhœa, which set in a few days previously. The wound was firmly healed, and there was no evidence of peritonitis. The specimen showed the stomach walls enormously thickened, white externally, discoloured internally. The different layers of the walls were undistinguishable. The orifices were of normal size. The transverse colon behind was also the seat of colloid degeneration, but not to the same extent. The duodenum was healthy. The orifices of the stomach were scarcely altered in size. The pancreas and spleen were firmly adherent to the stomach, and seemed to be involved in the disease, but the liver was healthy. The great omentum presented a hard, nodulated, cancerous ridge at its junction with the stomach. Dr. Franks alluded to three cases presented to the Pathological Society by the late Dr. Stokes, and to drawings of them which Dr. Foot possessed. Microscopical sections, showing the colloid nature of the disease, were prepared by Dr. Bewley, and exhibited to the meeting.—Dr. FOOT said this was an uncommon form of carcinoma of the stomach, and he believed it to belong to a class which would never be successfully operated on, the reason being that an extensive and widespread infiltration of the pylorus, and sometimes as far as the œsophageal opening, preceded the formation of any tumour. In the cases represented by the three drawings which he laid before the Section, the stomachs were gradually diminished in size by growths projecting on the mucous surface towards the interior of the stomach; and in some of these cases the stomach was reduced to the size of the small intestine. According to Cruveilhier, the information about this form of cancer might be summed up under three heads—viz., first, it was the form of gastric carcinoma the local symptoms of which were the most obscure; secondly, it was the form in which the cachexia was least pronounced; and, thirdly, it was the form in which ulceration was rarest.

Dr. A. H. BENSON showed sections of a Fibrous Tumour which he had removed by dissection from the anterior surface of the apex of the Cornea of a girl aged nineteen, otherwise healthy. It had commenced near the apex of the cornea about three years previously, and had slowly grown in density and extent, without any past or present sign of inflammation in its neighbourhood. It was of a dense white colour, measured about 4 mm. in diameter and 1 mm. in thickness, and was raised above the surface of the surrounding cornea, with sharply-defined margin. Its surface was evenly covered by the corneal epithelium. When dissected off, the cornea under it was perfectly transparent and normal-looking. There was no vascularity in or about the tumour, or anywhere in the cornea; nor was there any history of such having been present at any time. The tumour commenced and grew painlessly. Microscopic examination showed it to consist of apparently normal corneal tissue, with cells and corpuscles. It seemed to be a case of true corneal tumour, though Alt, in his "Histologie des Auges," p. 40, states his disbelief in the occurrence of such. This tumour had nothing whatever to do with the limbus conjunctivæ or the episcleral tissue, the usual origin of so-called corneal tumours.—Mr. STORY asked if there were any bloodvessels in connexion with the tumour. It would be curious to find a tumour of such a character and in such a site without any vascular connexion.—Dr. PURSER remarked that Bowman, in his work on the parts concerned in operations on the eye, had figured a growth on the surface of the cornea consisting of papillæ. Perhaps Dr. Benson's tumour was of that character. From Dr. Benson's description he should imagine that the tumour consisted of papillæ growing on the surface of the cornea—in fact, it was like a wart on the surface of the cornea.—Dr. BENSON, in reply, said there were no bloodvessels in the tumour or cornea, or any opacity that might be the remains of bloodvessels previously existing, or any history of any previous condition of congestion of the eye which might have been the seat of vascular communication between the tumour and the margin of the cornea. The tumour was perfectly smooth and fine. There was no nodulation, or even bossing up of the central part of the cornea.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Oct. 28th, Dr. Cleaver, President, in the chair.

Ophthalmic Cases.—Mr. SNELL introduced two patients. 1. Splinter of Steel removed from Lens Capsule by Electro-magnet. The man had been struck at his work five or six months ago, but only very recently sought advice on account of increasing impairment of vision, occasioned by opacity of lens. A coloured spot in the centre of the anterior capsule was presumed to be the splinter. Ten days since, on holding the electro-magnet in contact with the cornea for a little time, the fragment sprang forward to the posterior corneal surface. On his lying on the couch for removal, the splinter was nowhere visible, but on again applying the electro-magnet it once more came to a convenient spot and was readily effected with a small wound. The in-

complete cataract was left for subsequent treatment. The fragment weighed ·0001 gramme, and Mr. Snell stated that he had now removed about sixty pieces of steel or iron from various parts of the eye with his electro-magnet. 2. Paralysis of Internal Rectus from a blow over the eye with fist. The patient was a youth; the eye internally was uninjured, and at first ecchymosis was the only external symptom. Five days after the accident diplopia was noticed, and then the deficient action of the right internal rectus was distinct; three weeks after the injury the condition remained about the same. The direct cause of the condition was obscure; the blow was chiefly felt at the inner side of the eye, where there was tenderness. No evidence of rupture of muscle. Was the tendon crushed or torn, or was the branch of nerve similarly injured or interfered with by hæmorrhage?

Mediastinal Tumour.—Mr. PRIESTLEY exhibited a specimen of mediastinal growth in a patient of Dr. Dyson who had suffered from acute pneumonia. The growth consisted of a mass of caseating glands. The patient had a remarkable distribution of superficial arteries on his back, and the pulsation of the left subclavian could be felt below the left clavicle. Whilst under treatment the pneumonic symptoms were most prominent. The specimen was referred to the Pathological Committee to report upon.

Enlarged Spleen.—Dr. PORTER showed a large spleen from a case of splenic leukæmia. The patient had been under observation for nearly two years, and had presented the usual symptoms of progressive anæmia, emaciation, profuse sweats, epistaxis, great increase of white and diminution of red corpuscles in the blood, with great enlargement of the spleen and latterly of the liver, ascites, and some enlargement of the inguinal glands. The patient died of asthenia, hastened by hæmorrhages into the tissue of the mesentery and omentum, and excessive ascitic effusion, for which he was twice aspirated, with only temporary relief. Post mortem, besides the enlarged spleen, which consisted mostly of pulp and a large fatty liver, enlargement of the mesenteric and lumbar glands was found, and abundant lymphoid deposits in both mesentery and omentum.

Hydrophobia.—Dr. SIDNEY ROBERTS related a case of this disease occurring in a boy of five years under his care at the Public Hospital. The child was bitten on the thumb, which was at the time (half an hour after the bite) cauterised with nitrate of silver. Symptoms began on the forty-second day after the bite with restlessness and pain in the bitten part; on the forty-fifth he refused food and drink. He died on the forty-eighth day after the bite. Salivation was conspicuous by its absence thoughout the disease; there were no lyssi. Various remedies were administered, but chloroform inhalations was the only remedy that afforded temporary relief. An interesting point was that two other children were bitten by the same dog, one an hour and the other only five minutes previously. Both were sent to Pasteur fifty days after the bite and are now, eighty-three days after the bite, in robust health.

Pasteur's Treatment of Hydrophobia.—Dr. WHITE read a paper on this subject, founded on his observations made in a recent visit to Paris. He briefly adverted to Professor Pasteur's work in connexion with splenic fever in cattle, as illustrating the path which the great experimenter followed when he commenced the study of rabies, and related the facts which Pasteur had discovered in his study of the disease in animals—viz.: 1. That the nervous system is *par excellence* the seat of the rabies poison. 2. That the disease can be, with great certainty, transmitted through a long series of animals by trephining the skull, and introducing through the opening thus made a portion of rabid nerve tissue. 3. That passage of the poison through a series of rabbits intensifies it; and that a similar passage through a series of monkeys decreases its virulence. 4. That exposure of a highly virulent nerve tissue to the action of dry air decreases and finally destroys its virulence. 5. That if a dog be treated by inoculation with the attenuated virus of the monkey, or that from the rabbit, after prolonged exposure to air, it remains insusceptible to subsequent inoculations of the most intense virus of rabies. 6. That owing to the long period of incubation in dogs bitten by rabid dogs, it was possible to anticipate, and so avert, the advent of rabies in dogs already bitten by inoculating them with the attenuated virus. Dr. White claimed that Pasteur had demonstrated absolutely by the most rigorous tests his ability to protect dogs [illegible] Pasteur's patients who have bee[illegible] dition was ascertained [illegible] ½ per cent. Dr. White described in detail the processes whereby the vaccines are prepared; and concluded his paper by reviewing the various theories which seem to shed light on the manner in which the body is protected from the poison of rabies by inoculation.—Mr. Walker, Mr. Favell, and Dr. Potter joined in the discussion.

Tumour of Stomach.—Mr. FAVELL exhibited this specimen from a middle-aged man who during life had suffered very little from stomach symptoms. He appeared only to have vomited once, and the pain experienced was relieved by eating. He suffered chiefly from bladder symptoms. The tumour was a large cauliflower-looking growth, and was found growing from the concave curvature of the stomach. The specimen was referred to the Pathological Committee to report upon.

Aseptic Surgery.—The PRESIDENT (Dr. Cleaver) gave an address on this subject, and laid particular stress upon the fact that many surgeons imagined they were practising aseptic surgery when in reality they were only treating with antiseptics, of which there were many methods, and all of them more or less imperfect; whereas in aseptic surgery there was only one method—viz., that introduced by Sir Joseph Lister, which aimed at and attained a complete absence of putrefaction, and is therefore designated aseptic. Another fatal error was that aseptic or Listerian surgery was spoken of as treatment by the spray; on the other hand, Sir J. Lister, in an address to the Surgical Section of the International Medical Congress in London in 1881, brought forward results of investigations he had made tending to show that the atmospheric dust is not nearly so much to be dreaded as we used to assume, and that the various forms of virus are far more likely to be introduced by contact with infected liquids or solids than from the air. Dr. Cleaver claimed as one of the results of aseptic surgery complete immunity from infectious disease, including pyæmia, septicæmia, erysipelas, and hospital gangrene. In upwards of 300 cases of major operations performed at the Sheffield Hospital for Children during the last few years, not a single case of these diseases had arisen.—Remarks were made by Mr. Pye-Smith, Mr. Jackson, Mr. Favell, Dr. Martin, Dr. Gwynne, Dr. Keeling, Mr. Garrard, and Mr. Knight.

MIDLAND MEDICAL SOCIETY.

AT the meeting of this Society on the 10th ult., Mr. Lloyd Owen, President, in the chair, the following specimens were shown:—

Borborygmi.—Mr. S. C. LAWRENCE showed a girl, aged eighteen, who for the last fifteen months had been subject to constant "borborygmi." These sounds were audible at a distance of some yards, and were synchronous with the respiratory movements; they ceased when she was asleep, lying down, or holding her breath. They had obstinately resisted all treatment, and were regarded as hysterical.

Dermoid Tumour of Ovary.—Dr. MALINS showed a dermoid cyst of the ovary that he had successfully removed from a patient aged fifty-one. It contained a large quantity of light-brown hair, a well-formed tooth, and some bony plates, besides much thick fluid.

Convergent Squint.—Mr. EALES showed a woman, aged twenty-two, suffering from complete paralysis of both external recti muscles. She consulted him on account of convergent strabismus, which the mother stated was noticed at birth, and had been present ever since. V = $\frac{6}{9}$. H = ·50 dioptre; accommodation was good in each eye, and there was no other symptom present. She had no binocular vision, even for near objects. Division of the left internal rectus had gratified her by curing the obvious squint, but she had neither binocular vision nor was troubled with diplopia, though there was still some slight strabismus convergens.

Myxœdema.—Dr. SUCKLING showed a man aged forty suffering from myxœdema. He had been ailing for two years, complaining of debility and malaise. He presented the usual symptoms of myxœdema in a typical manner; the urine was free from albumen, of a low specific gravity, and deficient in urea. There was no reduplication of the heart sound, but feebleness of the circulation was a marked feature, the extremities always being cold, and the pulse small and of low tension; the temperature was 97·5 F.

Dr. SAUNDBY read a paper on the Treatment of Diabetes [illegible] mellitus.

Reviews and Notices of Books.

The Surgical Diseases of Children. By EDMUND OWEN, M.B., F.R.C.S. London: Cassell and Co. Pp. 518. 1885.

CASSELL'S "Clinical Manuals" have been so good and have established for themselves such a high standard that we now come to their criticism with rather exalted anticipations. It is perhaps on this account that we must plead to a feeling of disappointment in the volume before us; not that the volume is without merit, but that it is less meritorious than it might have been, seeing how its author had at his disposal the clinical and pathological records, statistics, and illustrations of the Hospital for Sick Children since its foundation—records &c. which in their special detail and excellence are probably not to be equalled at any other institution of the same kind.

Passing, however, from what is not to what is contained in this work, we would, in the first place, venture to regret the absence of all system in the arrangement of the matters discussed, and the very unequal attention bestowed on these matters. Let us glance at the Table of Contents. The Introductory Remarks are followed immediately by chapters on Diphtheria and on Tracheotomy. Would it not have been wiser to make the student acquainted with the diatheses of childhood, syphilis, rickets, scrofula, and the like to teach him, in fact, something of the conditions which influence and modify disease and its treatment in young subjects—before discussing so vague and difficult a subject as diphtheria or tracheotomy? Further down this table we find a chapter on Nævus, followed by another on Empyema; then one on Burns and Scalds, followed by another on Infantile Paralysis. The chapter on the Genito-urinary Tract is cut short by those on the Rectum and Intestinal Obstruction, the Testis and its Coverings being then dealt with and followed by Hernia. It is impossible to conceive of any arrangement better calculated to render a difficult task more difficult for an author, or one more likely to puzzle a student, than this mixing up of subjects, which are neither clinically, pathologically, nor surgically associated.

Then, as regards individual subjects. The Introductory Remarks, consisting of some nine pages, discuss and dismiss a variety of subjects, such as the following: anæsthetics, temperature, pulse, tongue, proposed operations, scarlet fever, administration of medicines, leeches, poultices, and "how to bring up babies." If a book on the surgical diseases of children were wanted, surely such questions as the foregoing ought to have been dealt with in a more extended form, since they include much that makes children's diseases special. The paragraph on anæsthetics occupies barely eight lines. It is dogmatically stated that "chloroform is best adapted for the purpose": the reader is informed that "no painful operation or wearying examination should be conducted without the aid of an anæsthetic"; in other words, that chloroform must be constantly brought into use; yet there are no instructions as to its mode of administration, beyond that "at the Children's Hospital it is usually given on a piece of lint." A few hints as to the accidents likely to occur, and how to avoid them, might advantageously have been given. Even in empyema, where one lung is *hors de combat*, and the other not infrequently damaged, we find no caution enjoined: simply the statement "chloroform having been administered."

The chapter on Diphtheria includes a paragraph, with special heading, on "laryngismus stridulus." What the connexion may be we quite fail to perceive. Then chronic laryngitis, we are told, "is often the result of congenital syphilis. ..... It may be treated by a couple of leeches over the trachea." Several other alternatives mentioned "are useful in various phases of the disease." Not only are phases not described, but we are left in ignorance as to when or how to apply one remedy in preference to another. Why not have included chronic laryngitis under its asserted causation, and described it more fully?

Tracheotomy is dealt with in much the same casual way. It is illustrated with three woodcuts, one of which is Spencer Wells' compression forceps, now so well known as not to require illustration; another is an old-fashioned tapering Fuller's bivalve cannula with a rigid neck-plate. This form of cannula, occasionally useful in an emergency, is here recommended for general use. As regards size, we are told that "for small children the lumen of the outer tube, at the level of the plate, may be about the size of an ordinary steel penholder, and for larger children of the size of a cedar pencil." These instructions are somewhat vague; in a subject of such moment they might even be more severely characterised. This chapter (on tracheotomy) closes with a paragraph on "papillomata of the larynx," consisting of fifteen lines for history, diagnosis, and treatment.

In considering the Diatheses of Childhood, the author introduces a condition we have not yet heard of in this connexion—"children out of condition"; but the half-page devoted to it contains nothing which, in our opinion, justifies its removal from the place usually assigned to the subject—viz., the introductory remarks or chapter.

Among the symptoms of Congenital Syphilis we meet with the following dogma: "An eczema which extends up the abdomen and down the lower part of the thighs—that is, beyond the region enclosed in the napkins—is of syphilitic origin." Visceral syphilis is not even mentioned. A coloured drawing representing condylomata, and referred to in this chapter, will be found (owing, doubtless, to careless editing) many pages further on among rachitic deformities. We cannot commend this drawing; the mucous patches are usually broader, larger, and less elevated than here represented; as shown, they look like warts, and might well serve for contagious molluscum, and be less likely to mislead.

Rickets is discussed chiefly as if it were a disorder of the bones, first under diatheses, and further on under rachitic deformities. But neither this subject nor syphilis is treated in the orderly manner we should have expected in the special work before us; the author does not attempt anything like a chronological sequence of the manifestations of these diseases as they occur at various ages, from infancy onwards.

Concerning Strumous Glands, we read: "A common cause of enlargement is irritation of the pharyngeal mucous membrane by *sewer gas*." After relating how the children of three distinct families, one of which "was markedly strumous," got cervical abscess after exposure to sewer gas, the author says, "The use of the word struma must not be made a scapegoat in an endeavour to explain the occurrence of glandular enlargements when no other source of irritation happens to be discoverable." While agreeing generally with this caution, we venture to claim an equal indulgence for "sewer gas" under like circumstances.

In discussing the treatment of Empyema, the author says, "The site recommended for the opening of the pleural abscess is the fifth intercostal space, at the junction of the anterior third with the posterior two-thirds." This spot may be very well when the abscess cavity happens to be seated here, or even when there is an abscess occupying the whole or a considerable part of the chest; but we do not think the fifth space quite the best, and prefer the sixth. We also differ in regard to the exact part of the space for the opening; the junction of the anterior third with the posterior two-thirds is, we think, too far forwards for satisfactory drainage in the recumbent position, and places the [illegible] in the above-named cases of operating incised to puncture at the selected

spot is made with a fine trocar and cannula, and a grooved director is passed along the track into the pleural cavity. Along the groove a probe-pointed bistoury is then thrust, and an incision about an inch in length is made through the space. The incision is subsequently enlarged by thrusting in the end of the finger, and working it along between the ribs." To say nothing of the difficulty of such a proceeding, is it well to recommend a student to thrust in the end of his finger, and work it along between the ribs in order to enlarge an incision? Would he not find a sharp scalpel far more to the purpose? Mr. Parker is said to have invented a useful double drainage-tube, illustrated in a woodcut. We believe it would be more correct to credit Mr. Scott Battams with this invention, which from experience we can speak highly of.

A propos of the diagnosis of Spinal Caries, we are told that if a child prefers a cautious descent downstairs by the aid of the balusters, and refuses "to jump from the bottom step," the diagnosis is clear. Does the author really offer this as a serious statement in a book written largely for students?

With regard to the chapter on Fractures, the book would have lost nothing had it been left out. On the other hand, a systematic account of the anatomy of the epiphyses at various ages, and of the injuries and diseases to which they are liable, would have greatly enhanced its value, and indeed should have been regarded as a *sine qud non* in a surgical work on children's diseases.

Our perusal of other chapters brings us face to face with the same want of thoroughness—the same want of system in the treatment of the subjects discussed. Why not have abstracted some typical histories from the hospital note-books, instead of giving quotations first from one writer, then from another, often without any indication of what the author himself thinks best? Some of the chapters commence with a paragraph on the development of the organs under consideration, but this is so brief that it quite fails in its object. So, too, with the illustrations—they are not sufficiently obvious. Take for instance Fig. 21, representing the Development of Face. "Quain's Anatomy" is almost essential to make its bearing quite clear to the student.

We will now close this notice—not because we have exhausted the points open to criticism, but because we have said enough to justify the disappointment which we admitted to have felt in first glancing through the book. This feeling has increased rather than otherwise as we have more carefully studied the chapters. If the author will only take our criticisms kindly to heart, he will set about a reconstruction of his book and a re-writing of his chapters such as will ensure a really useful work when the second edition is called for. Should such a course be taken, our criticisms will have fulfilled the object we aim at in respectfully offering them.

The Member, the Fellow, and the Franchise. By JOHN ERIC ERICHSEN, F.R.C.S., F.R.S., Surgeon Extraordinary to Her Majesty the Queen, &c. London: H. K. Lewis. 1886. pp. 16.

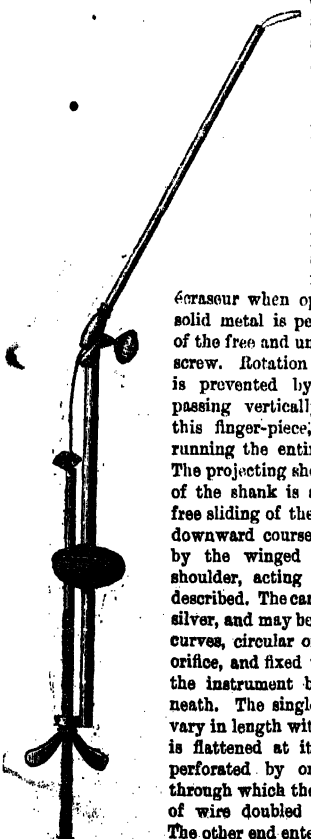
THE present pamphlet is a somewhat amplified edition of the speech its author delivered at the College of Surgeons on Nov. 4th at the general meeting. We must pass over the opening paragraphs, without, however, on that account, be it said, endorsing the author's eulogy of the College of Surgeons, many of these statements being as visionary as the "vastness of its acquired wealth," to which allusion is made in proof of the wisdom and excellence of the policy hitherto pursued by the Council.

Considerable stress is laid on the fact that Licentiates of the College of Physicians and of the Apothecaries' Society have no status beyond their licence to practise; it is argued that the Members of the College of Surgeons stand exactly on the same level, and therefore should have none. We must remind Mr. Erichsen that [illegible] bestows not a mere licence [illegible] the body corporate [illegible] the ancient privileges formerly enjoyed (and enjoyed by all alike) by those who belonged to the corporation, and that to interpret the full meaning of this term we must go back to the origin and growth of the College. Let those who are interested in the matter refer to our columns of Oct. 30th, where a brief *résumé* of the history of the College will be found.

Mr. Erichsen's contention that the Members are not at present entitled to electoral privileges is indisputable; he is wrong in saying that Members urge a legal claim. On the contrary, they urge a claim similar to that put forth in 1843, when, as a result of this claim, the Fellowship was instituted, and they have now an equal right at least to do so. The Members, who in and after 1843 by the new Charter were elected Fellows, stood exactly on the same footing as regards their legal claim as do the Members of to-day. But whereas in 1843 a very limited number of the Members were made eligible for the electoral privilege, it is now sought to do justice to all alike, and to confer the electoral franchise on all Members of a certain standing.

Mr. Erichsen states that the business of the College is not political, not ethical, and not commercial. In the sense that the College cannot exercise any political influence, that it attempts but little ethical control over its Members, and that it does not conduct its affairs on ordinary commercial lines, this statement is strictly true. Whether, however, this is as it should be, is quite another question.

We are told that the business of the College is educational and scientific, and "that the supervision of surgical education and the conduct of those examinations by which it is controlled can only be efficiently done by men who are thoroughly trained to that sort of work." The author proceeds, "probably at least 1000 (of the 1140) Fellows are general practitioners." It therefore follows that he would practically limit the management of the College to the remaining 140; in other words, Mr. Erichsen would re-establish the monopoly which the institution of the Fellowship, it was hoped, would put an end to. Provincial Fellows will do well to note this argument. With the exception of some 140 favoured Fellows none are fit to participate in College concerns. By "favoured" we mean of course London Fellows, for the Council have, until quite recently, insisted on personal voting, which practically shuts out the majority of provincial Fellows from an expression of their views. Mr. Erichsen knows "of only one teacher of anatomy of any distinction who is not a Fellow." Are there not two at least at University College? He need only turn his eyes to other schools in order to convince himself how unjust this remark is to men of great distinction as anatomists, not in London only, but in Edinburgh, Aberdeen, Glasgow, and other places. Has he forgotten such men as Huxley, W. K. Parker, Ward, and a host of others? On this showing is it not strange that the Fellowship is not a necessary qualification for the "endowed lectureships," of which Mr. Erichsen speaks so enthusiastically in the early part of his pamphlet?



Mr. Erichsen would further support the *status quo* by appealing to the scientific acquirements of many members of Council. "Where are to be found the men of science connected with the College of Surgeons? Are they amongst its Fellows or in the ranks of its Members?" he asks. Guaged by the test of the "coveted distinction of the F.R.S.," Mr. Erichsen implies that Fellows only obtain it, and yet the very first name mentioned in this connexion is that of Sir James Paget. Now Sir James Paget, of all living men, is about the best instance of what can be accomplished without the academic test on which Mr. Erichsen lays so much stress. For Sir James is a Fellow by election and not by examination; like all the *elected* Fellows, therefore, his position is that of a Member as regards examination tests, while his status and privileges are those of the higher grade. A glance at the College Register reveals that Owen, Quain, Busk, Hewett, [illegible]ett, Simon, Bowman, Spencer Wells, Humphry, and [illegible]hers are Fellows by *election* and *not by examination.*

These are names to be proud of, and are, and will remain, evidences of how much depends on the man, how little on the mere examination test, and will serve to show that the highest scientific attainments and reputation in no way depend on the Fellowship of the College by examination, to which Mr. Erichsen attaches such an undue importance.

New Inventions.

AN IMPROVED NASAL ÉCRASEUR.

SIMPLICITY of construction, lightness combined with strength, and durability, are the essentials of a good nasal polypus snare. The rapidity with which the steel wire loop may be adjusted to the instrument should also be considered in the selection of a snare. The accompanying woodcut is intended to represent an appliance for which all the above advantages are claimed. This snare-écraseur may be described as consisting of four parts. The main body or shank has inserted at its angle a grooved wheel or pulley. A screw runs parallel with the shank, with a winged milled nut at its lower end; a cannula and a single steel wire loop drawer. The body of the instrument is constructed of steel of a superior quality, and is provided with the grooved wheel before referred to at its upper extremity, a finger-piece at or about its middle, and a projecting shoulder at its lower end. Over this revolving wheel the steel wire loop drawer passes, thereby reducing to a minimum the friction and loss of power that would otherwise be considerable. The finger-piece is one with the shank, and is intended for securely holding the écraseur when operating. This piece of solid metal is perforated so as to allow of the free and unimpeded passage of the screw. Rotation of the latter on its axis is prevented by a small steel point passing vertically downwards through this finger-piece, and entering a slot running the entire length of the screw. The projecting shoulder at the lower end of the shank is also perforated for the free sliding of the screw in its upward or downward course. Traction is obtained by the winged nut, external to the shoulder, acting on the screw already described. The cannula is made of German silver, and may be of varying lengths and curves, circular or flattened at its nasal orifice, and fixed to the body or shank of the instrument by a set screw underneath. The single wire loop-drawer will vary in length with that of the cannula, is flattened at its free extremity, and perforated by one or more openings, through which the ends of a small piece of wire doubled into a loop are fixed. The other end enters the nearest point of the screw, and is secured by a set screw on its side. A pear-shaped extremity is brazed to the screw end of the wire to lessen the liability to slip when undergoing a severe strain. When the winged nut has worked up the screw, the latter is drawn backwards, pulling the single wire loop-drawer and its attached loop further into the cannula, and thus the growth or hypertrophy is snared with expedition and with but little effort. The snare as described possesses all the power of the straight instrument, with the additional advantage that the operator's hand is out of his line of vision. The grooved wheel or pulley was applied by the writer for the first time in the history of nasal snares to a modification of Wilde's original model in common use in Germany. This instrument (Krause's) differs from the snare ordinarily employed in Germany and Austria in having the single wire loop-drawer (*Drahtstange*) substituted for the long wire loop. In justice to Dr. Sajous of Philadelphia it must be stated that he introduced the same principle of attaching a short length of wire loop to a single rod or stile in his straight snare écraseur several years ago. The advantage of this method of attachment is that the rotation of a short loop on its axis is much less likely to occur than in a loop of greater length. The original of the instrument illustrated was made to order by H. Pfau, Dorotheenstrasse 67, Berlin. Messrs. Maw, Son, and Thompson, of Aldersgate-street, are prepared to supply the écraseur as described.

GEORGE W. MAJOR, M.D. Montreal.

TENNIS ELBOW-CAP.

MESSRS. POPE and PLANTE, of Waterloo-place, have brought out a cap for the elbow in cases where the muscular parts about the joint have been overworked at tennis. It is composed of cotton or silk elastic, which completely surrounds the arm, extending for some distance above and below the joint, the part below being strengthened by a band one inch and a half below the joint. They recommend its use when the arm is recovering from a strain, and there is no prolonged return of tenderness or of pain on lifting a weight of about four pounds. It is only to be used during gentle play. Our experience of its use is that whilst it affords relief and support to the part, it also produces discomfort of the arm below from obstruction to the superficial veins, congestion rapidly following the frequent movements of the forearm, accompanied by a feeling of fulness and heat if the cap is too tight. Accurate measurement is required. It is called the Cavendish Elbow-cap.

THE METROPOLITAN INFIRMARIES.

AT a meeting of the medical superintendents of the metropolitan infirmaries, held at the Lambeth Infirmary on Nov. 25th, Dr. Lloyd in the chair, the following resolutions were agreed to:—

1. Moved by Dr. Saville, and seconded by Dr. Webster,—"That, in view of the differentiation into departments which the science of medicine has undergone of recent years, the opinion of the boards of guardians be obtained as to the desirability of appointing specialists of eminence as honorary consultants to Poor-law infirmaries, who shall be available for consultation with the medical superintendents; such consultants not to have any power in the administration of these institutions, as set forth in the regulations now in existence at the various metropolitan infirmaries. And that a copy of this resolution be forwarded to the medical superintendent of each metropolitan infirmary."

2. Moved by Dr. Webster, and seconded by Dr. Lund,—"That it is desirable that an increased medical staff be provided in the metropolitan infirmaries, in the form of a resident qualified clinical assistant (with board and lodging), in addition to the medical superintendent; but that such clinical assistant should not supplant the present assistant medical officer."

It [illegible] these resolutions stand [illegible] at a meeting to be held

THE LANCET.

LONDON: SATURDAY, DECEMBER 4, 1886.

WE announced in our second edition, published on Friday last at 5 P.M., that Mr. WHEELHOUSE, Sir WALTER FOSTER, and Dr. GLOVER had been elected the direct representatives for England and Wales to the General Medical Council, with the actual numbers polled by each; thus the anxiously expected result was known throughout England and Wales on Saturday morning. There can be no need of any apology for again referring to this election, the great importance of which we have more than once impressed upon our readers, not only with regard to the choice of candidates, but even more as an indication of the public spirit in the profession, and of its interest in and appreciation of direct representation on the General Medical Council. Many prophecies have been indulged in, some hopeful, others adverse; but we doubt if anyone ever dared to foretell that so large a number as 13,381 in England alone would vote when the total on the Register is 18,074. Yet this is the fact. A poll of one-half of the Register would have been a success, but a poll of over two-thirds is such an unlooked-for response to the trust that Parliament has reposed in the profession that it ought to silence once and for all those who affect to believe that direct representation was a "cry" got up by interested parties, and was in no sense a genuine and strongly felt need of the profession. The result has conclusively shown a remarkably general and widespread interest in the election.

Another matter which fairly calls for praise is the mode in which the election has been carried out. Opinions will no doubt, differ as to the conduct of different candidates and committees, but when we bear in mind the suddenness with which the election came upon the great body of practitioners, the entire lack of experience of similar electoral contests, the widely distributed electorate, and the other obvious difficulties in the management of a canvass, the features of the election, on the whole, must be regarded as satisfactory. It is also satisfactory to learn that those elected have been returned by very substantial majorities over the other candidates. If we look at the poll for England and Wales, we find that Mr. WHEELHOUSE received a vote from very nearly one-half of the entire body of electors; and that Dr. GLOVER, who was supported by a full third of those entitled to vote, has a majority of nearly 2000 over the candidate who stands next to him on the poll. With so many candidates for the three seats the results might have been very different, and it is certainly a great advantage for those who will speak with unique authority at the Council to know that they have been supported by the great body of the profession in general, and that they do not owe their election to small majorities. Like all minorities, those defeated will not look upon the verdict as irrevocable, but will endeavour at a future time to turn their minorities into majorities. If they succeed in this, we hope that their success will [illegible] who have been returned [illegible]

We have all along contended that it was most important that those who were returned as the direct representatives should be really such, and not men of the same interests as those already having seats on the Council. We rejoice to see that this principle has been largely successful. In England all three of the members will, we believe, represent the wants and aspirations of the general practitioners of medicine. By their wide acquaintance with the profession in all its branches, by their public action and well-known sympathies, they have shown themselves well able to represent the thousands whose votes have placed them at the head of the poll. In Scotland the same may be heartily said of the return of Dr. BRUCE over the head of a candidate whose connexion with a corporation was too close to enable him to represent the general practitioners of Scotland. In Ireland alone has this principle been completely disregarded by the majority. Not only is Dr. KIDD, the successful candidate, a member of the Council of the College of Surgeons, and an ex-president of that body, but his return keeps the representation of the entire profession in Ireland—corporate and otherwise—in the hands of Dublin men. This is undoubtedly a pity, and ought to be corrected whenever the opportunity for it arises. So far as the return of actual general practitioners is concerned, the election has been in some measure a success. In Scotland Dr. BRUCE, and in England Dr. GLOVER, are typical general practitioners; and although Mr. WHEELHOUSE can scarcely claim that title now, it certainly fitly described him for a large part of his honourable career.

In one word we may be permitted to refer to the position taken by THE LANCET. We have strenuously contended that the electors should be left absolutely free and unhampered in their exercise of the franchise. We have repeatedly drawn attention to principles rather than to men; we have urged our readers to exercise their right in accordance with these principles, but we have not pressed the claims of individuals. One argument that has been used against the gift of "direct representation" has been that the elections would be in the hands of the medical press. We have endeavoured—we believe with success—not to interfere in any improper or questionable way with the vote of any one of our readers; and this in spite of the fact that Dr. GLOVER is, and has long been, a very valued member of our editorial staff. We rejoice in his success, and all the more that it has been won without the aid which might have been afforded him in our columns.

THE importance of life insurance to all those who have others dependent upon them is so obvious that it would seem superfluous to advocate its more general adoption at the present time; and yet it is surprising how many men there are with wives and families, having an income more or less precarious, and no private means, who have not made this almost necessary provision for those whom they might at any time leave wholly unprovided for. To no men do more harrowing scenes occur of widows and fatherless children left utterly destitute, than to members of the medical profession. The breadwinner has been carried off at the end it may be of a long illness, and after the due discharge of all outstanding bills and funeral expenses there [illegible] found to be no policy of insurance, and nothing left save

household furniture. It is well indeed if matters are not worse than this, and the unfortunate widow left with debts to be paid. One would naturally have expected that with these harrowing sights in recollection all such members of our profession as are wholly dependent upon it for the support of themselves, their wives, and families, would have taken the precaution of having a policy in one of the many well-established life offices, which are not only willing, but anxious, to increase the number of their "assured," always provided that the lives are fair average ones. But, as any one who reads this may ascertain by inquiry among his friends, medical or lay, life insurance is still very far from being so general as it should be. If such persons are asked why they have not become policy-holders, various reasons are assigned. For example, one probable, and apparently logical, reason will be that the person questioned does not see the advantage of life insurance, since, if he should live to a good old age, his relatives will only receive what he has probably paid in premiums. This objection is easily answered. Life assurance is a provision against the uncertainty of life, and although medical applicants are, *cæteris paribus*, accepted as good lives, in no profession is the uncertainty of life more plainly illustrated than in that of medicine. Instances might be given and multiplied, but it is sufficient to say that every office could adduce cases where the sum insured has been paid within a very short period after the policy has been issued, and where only one premium has been paid. But should the applicant live to a good old age, has he done wisely in insuring? Undoubtedly he has. If as is now usual, he insure with profits, and in a well-established office the policy will increase in value each succeeding year, and may become double the original amount. In either case therefore the taking out of a policy of insurance on his life is to every medical man a good investment, and every medical practitioner would do well to insure against accident whereby he may receive a weekly sum in case of total or partial disablement, while in the event of a fatal accident his relatives will receive the capital sum. A more general adoption of these wise—might we not say necessary?—provisions for the future would render unnecessary most of those heart-rending appeals for the widows and orphans of medical men which appear so often in our columns, and those of our contemporaries.

An excellent means of promoting life insurance is by parents insuring their sons' lives as soon as they are insurable, say, at the age of fifteen. The premiums are low and remain so, and when the assured is old enough to take up the policy, he may be said to have, owing to the wise provision of his father, a small capital or estate to dispose of. Should he unfortunately never reach "man's estate," but die young, there is the capital sum to leave to parents, brothers, or sisters, instead of being wholly dependent upon them. And, like all other measures taken out in an honest spirit, life insurance brings good in its train. It inculcates habits of thrift and prudence; it compels a man to save up at least a portion of his income for others; and it affords great relief from the otherwise harassing care which must weigh upon everyone who thinks upon what will happen when he is gone, and how loved ones will be comfortably provided for.

FURTHER communications have been made to the Académie des Sciences by M. GUIDO TIZZONI on the pathology of suprarenal capsules. The last paper deals with the functional and structural alterations that occur in the nervous system after the extirpation of these organs. The functional derangements have been observed in five rabbits operated on after the following manner. In one rabbit both suprarenal capsules had been removed fifteen months; in another the right capsule had been extirpated twenty-four days and the left six; in the remaining three animals the right capsule only had been excised nine, eighteen, and twenty-two months respectively. The lesions of the capsules were proved in seven animals; the five above mentioned and two others were killed at the end of nine and twelve months respectively, without having shown the least sign of functional disturbance. The nervous symptoms appear to be related to the brain and medulla oblongata. The animal moved with less ease and refused nourishment; soon it became comatose, spread its legs to prevent its falling, and dropped its head; it was seized with trembling and a tendency to be propelled forwards; mere touching excited a transient opisthotonos, or jerking and exaggerated movements; convulsive seizures, opisthotonos, and violent spasms preceded death. There was also diminution of mobility and sensibility (to pain and electrical excitation) and reflex action, especially in the anterior extremities; mydriasis, acceleration of respiration during the spasms, slowing of the same during the intervals, redness of the buccal mucous membrane, lowering of temperature, and finally rapid rigor mortis. The lesions observed were great injection of vessels in the central nervous system, and hæmorrhagic foci in the grey matter of the cord about the anterior horns and neighbourhood of the central canal, if death occurred soon after the operation. When death follows the operation at a longer interval the lesions are found in the pia mater and subarachnoid space, in the cavities and ventricular walls. There is an exudation with fibrous reticulum in the subarachnoid space, which contains also an amorphous, granular substance, rich in white cells and droplets of myelin. Branched villous outgrowths fill a large part of the ventricular cavities, which are also the seat of an exudation still richer in formed elements than that in the subarachnoid space. The leucocytal infiltration may be followed into the substance of the brain and cerebellum, where foci of cells and fibres have been destroyed and the epithelium of the cavity shed. These lesions correspond in distribution to the pia mater, and affect a limited layer at the surface of the hemispheres or at the interior of the ventricles; but there are, besides, disseminated plaques of degeneration, with, at the same time, infiltration of the spinal cord, and acute softening, commencing in the axial part of the nerve fibres and extending thence to the sheath. In the ependyma an exudation is found—sometimes of simple sort, sometimes attended with loss of epithelium and infiltration of the grey matter, penetration of leucocytes into the vascular walls, and disorganisation of the same; in fine, extension, either uniform or focal, of the morbid process into the grey matter, which may be replaced by globular masses or an amyloid substance. The same lesions are found in the walls and cavity of the fourth ventricle; the nerve nuclei of the [illegible] do not escape, and their cells are [illegible] infiltration, and dystrophy. [illegible] The intensity of the

changes diminishes from above downwards, and attains its maximum (*sic*) at the seat of the second and third dorsal pair. Roots, ganglia, and nerves may be also totally or partially degenerated. In the two cases where no lesions were found the posterior part of the cord was alone preserved, that which generally remains normal. These alterations are probably due primarily to vascular lesions, which in the acute cases lead to hæmorrhages, and in the more chronic ones to alteration of the cerebro-spinal fluid. This opinion is strengthened, TIZZONI believes, by the fact demonstrated by his former experiments (see THE LANCET, vol. ii. 1884, p. 549), that suprarenal regeneration takes its point of departure in the solar plexus; also by the analogy between the nervous lesions and those of the skin which NOTHNAGEL has shown to affect primarily the vessels of the cutis; and, finally, by the great resemblance between the disturbances observed by BROWN-SÉQUARD soon after extirpation of the organs, and those which TIZZONI has observed later. Two cases described by BURRESI and SEMMOLA demonstrate the occurrence of nervous disorders in man, like those which TIZZONI has described in rabbits, as the result of disease of the adrenal organs.

WE understand that a deputation from the Committee for promoting a Teaching University in London has waited on the Senate of the University of London, has laid the views of those interested in the success of such a university before the members of the Senate, and has received a satisfactory reply. We are glad to find that this movement is again being brought into notice, but fail to see how, after Sir J. PAGET'S remarks at Manchester, any common line of action between the proposed and the existing Universities can be arrived at; moreover, we doubt if the Vice-Chancellor went further than to suggest, with his well-known courtesy, that every consideration should be given to the proposals of the deputation. Some internal reforms in the present University, such as the formation of a Board of Studies, as a means of communication between the teachers and the Senate, and perhaps a reconstitution of the Senate so as to give increased representation thereon to the teachers in the two large London Colleges, may be effected by this movement; but this will not satisfy the general body of its supporters, who demand a real Teaching University. A paragraph in *The Times* of Monday last showed how intense this feeling is among certain of the London teachers, and were it not for the evidence it afforded of the eager craving existing for some solution of our present difficulty, would have been sufficiently grotesque. The Victoria University, in order to provide for the affiliation of the Yorkshire College of Science, or any new college that may be successfully started in the North of England, has a clause in its Charter by which "any incorporated College may be admitted as a College in the University, on the University Court being satisfied, (first) that the College applying has established a reasonably complete curriculum, and possesses a reasonably sufficient teaching staff in the departments of Arts and Sciences at least; (secondly) that the means and appliances of the College for its teaching are established on a [illegible] and (thirdly) that the College is under the [illegible] governing body." Power[illegible] fusal, for an appeal to the Privy Council. It is gravely suggested by some of the teachers at University College that this College should, under the above clause, become a constituent College of the Victoria University; and of course, if this application were made and was successful, King's College, the Mason College at Birmingham, and the University College at Bristol would at once follow suit. The students of the teaching Colleges of England would thus all be able to obtain degrees in arts, science, and medicine from the northern University, and no further Teaching University would be required; whilst the secession of Owens College and the University College of Liverpool from the University of London would be followed by every other fully-equipped college in the kingdom. The idea is so strikingly original, and is such an easy mode of cutting the Gordian knot, that it seems really a pity that it should have been officially announced as premature by the Secretary of University College on the very next day. It will probably have served its purpose if it brings the necessity of a real Teaching University more forcibly before those interested in the movement and the authorities of the existing University, and proves to them that no stone will be left unturned to obtain for London students degrees not only in medicine, but also in arts and science, on similar terms to those which are readily afforded by every University in the world except by the imperial examining board in this metropolis which bears the name of the University of London.

Annotations.

"Ne quid nimis."

THE AMALGAMATION OF THE EXAMINING BOARDS.

A LEGAL correspondent takes exception to our statement in a recent article that the action of the Royal Colleges of Physicians and Surgeons in refusing to amalgamate with the Apothecaries' Society for the purposes of examination has placed the public under a serious disadvantage. As one of the public, he asks how this can be the case, and points out that (1) if the Medical Council appoint assistant examiners for the purpose of creating the Apothecaries' Society an examining board, it is a positive requirement of the Act that they "shall maintain such standard of proficiency as is required from candidates for the qualifying examinations—i.e., possession of knowledge and skill for the efficient practice of medicine, surgery, and midwifery"; (2) the public, he urges, are not affected by the question whether the Apothecaries' Society will charge a lower fee; and (3) if the Privy Council were to refuse to appoint assistant examiners, and were to leave the present Conjoint Board as the sole examining board, the fees would not prevent men from entering the profession, and the public would therefore be able to get good doctors to treat them. Concerning the last of these objections we have only to reply that it is a possibility which need not be entertained. The Apothecaries' Society will doubtless be able to substantiate their claim to be an independent examining board, through the appointment of assistant examiners either by the Medical Council or by the Privy Council. With regard to the first two objections, we admit at once that the Act has endeavoured to guard against any undue lowering of their standard of proficiency; but this standard is not one that [illegible] be recorded as a mathematical expression from which [illegible] can be no deviation. If any circumstance should lead

the Colleges to believe that a lower standard was not undesirable, it is not difficult to see that the General Council, in view of the intimate relation of its members with those who control the affairs of the licensing bodies, might easily be led to fall in with the views of the Corporation in this respect. Such professional opinion must also have its influence upon the Privy Council; the standard might not be suddenly altered, but a gradual change might be brought about if the Colleges thought this change desirable. We do not need to show that this would be prejudicial to the public, and we have only to consider what circumstance could give rise to it. The existence of rivalry between different examining bodies alone could do this, and it is this rivalry that we have been desirous of seeing rendered an impossibility by the creation of one examining body. The principle of unity is obviously of so much advantage to the public that it was but right that the medical corporations should have made some sacrifice to preserve it. They have, however, considered too much what they believe to be their own interest, and have thought less of the chief object which it was intended by the Act to attain. This is a question which we believe concerns the public not less than it does the medical profession.

LORD SALISBURY ON HOSPITAL SUPPORT.

THERE is something very refreshing in seeing the Prime Minister of England, at a time of considerable social and public anxiety, devoting his mind to an argument in favour of hospital support. All honour to Lord Salisbury for doing so. His paper is contained in the *Hospital* for Nov. 27th, as also two other deliverances on the same subject by Sir Andrew Clark and Sir Sydney Waterlow respectively, two other undoubted friends of Hospitals. The case for supporting these institutions could not be stronger than it is, nor could the time be more opportune. Never were the hospitals more straitened. It is said gravely that one or two of the best will have to be closed if unforeseen help does not come. And Christmas is at hand, with its mystic sympathies and benevolent impulses. Is it imaginable that a hospital in London should be closed for want of funds? There have been black days when banks have been closed; but such days would appear bright compared with that in which a great London hospital shall close its doors because men have closed their pockets in a community whose income is to be counted by millions. Lord Salisbury admits the great depression of the present moment, but he points out that this very circumstance strengthens his argument. He shows that depression of trade increases the amount of misery and disease to be relieved. The Premier thinks that one disadvantage of the case of hospitals is that it is so plain—no one disputes their excellence. No one who has seriously gone into hospital wards and work will do so. But is his Lordship quite right in thinking the case so undisputed? There are many people nowadays who think it their duty to prate about the abuses of hospitals on the strength of a few exceptional cases, and who give no thought to the mass of pain and disease and disablement with which they grapple. Lord Salisbury is right in placing the claim of hospitals at the very top of all claims. When sickness and accident overtake the working man all other misfortunes follow—wages stop, nourishment is stinted, so is clothing. The case is one for ready help. No one that is in actual work can be excused from the duty of some contribution to these institutions. "No doubt," says Lord Salisbury, "the heavier call is upon the rich, but it is equally upon all, and this deficiency will never be filled up unless the masses of those whose incomes are not large will each feel the responsibility of contributing what he can to so glorious an object." The hospitals be as severe as they please in excluding ascertained unfitness; nothing can justify the admission of cases that can be treated as well at home, and that ought to be under the care of the ordinary practitioner, who as he has advanced in skill has only grown more considerate in his charges. But let a bed be made, and let all medical and nursing help be ready, for the sick poor in the great calamities of their life. Similar lessons are urged by Sir Andrew Clark and Sir Sydney Waterlow. Sir Andrew insists on the advantages of inter-communication between hospitals, and Sir Sydney on the enormous development of skilled nursing and its importance in sickness. Let us hope that Christmas benefactions will follow these great arguments, and lighten the heart of many an anxious hospital treasurer.

LEPROSY.

THE Hawaiian Legislature, in its determined efforts to try to control the spread of leprosy in the islands, was fortunate in securing the valuable services of Dr. Edward Arning for purposes of special research. He found the bacillus lepræ plentifully in all nodules and diffuse swellings of the tuberculated cases and in similar lesions of the mucous membrane of the mouth, throat, nose, rectum, and large intestine, and in the discharges from the ulcerated lesions. He recognises a diarrhœa arising from the leprous ulceration of the bowels closely simulating a true dysentery, and thinks that the deaths usually ascribed to intercurrent pneumonia, tubercular phthisis, and dysentery should be more correctly ascribed to breaking down of leprous infiltrations of the lungs and bowels. He failed to find the bacilli in the early bright-red patches of vaso-motor congestion due to nerve lesions, in the anæsthetic patches of the so-called "anæsthetic cases," and in the chronic sores of necrotic parts of skin tissue and bone, but they were present in the nerves supplying the mutilated parts. There were none in the urine and none in the blood, nor could he discover by culture or otherwise the existence of any spores in the latter fluid. All attempts to obtain an independent and pure growth of the bacillus lepræ failed, nor were inoculations of animals of various ages in different parts of the body succeeded by a general infection. Arning inoculated a condemned criminal, but fourteen months later no definite results had followed, though a few bacilli could still be detected in the scar. Lastly, he demonstrated a vitality persisting over several months of the bacillus lepræ in putrefying tissues. On the clinical side, researches in electro-diagnosis convinced him that the anæsthesia and paralysis are due to leprous disease of peripheral nerves, but he does not regard the muscular crippling as so characteristic of the disease as the bone affections. Coming to therapeutics, we notice that Arning administered iodide of potassium without any good effect, also hyposulphite of soda, salicylate of soda, creasote, carbolic acid, and arsenious acid; and with some good effect salicylic acid and hypodermic injections of corrosive sublimate. He observed the efficiency of electrical treatment in anæsthetic cases, and insists on the value of salicylic acid in a 10 per cent. paste or ointment or solution in oleic acid, and also of pyrogallic acid in a 10 per cent. ointment or strong solution in traumaticine. Arning declares that, for one reason or another, he found it impossible to obtain from questioning the natives reliable statistics on which to base proofs for the hereditary or congenital transmission of leprosy; but we note from other reports that amongst the cases of advanced leprosy at Molokai sterility is almost universal, and the majority of the offspring, where either one or both parents are diseased, have been stillborn or have died within a short period after birth, and of those who have survived many have not yet developed leprosy. No con- [illegible] but Arning saw two well- [illegible] ree and a half and four [illegible], whilst it is perfectly

true that healthy people may live with tuberculated lepers for years without contracting the disease, many on the other hand do not escape, and he especially refers to the remarkable percentage of the non-leprous assistants, or kokuas, on the settlement who contract the disease. Of 178 kokuas, 17 developed leprosy between Feb. 1885 and 1886.

GENERAL MAXWELL ON THE "BEAUFORT" LIMB.

IT was not in the nature of things that the artificial arms and legs of the Comte de Beaufort, served out annually by hundreds at home and abroad to the crippled poor, should in every case give satisfaction or escape the fault-finding which sometimes does duty for criticism. It is one thing to command success and another to deserve it; but that the good Count's invention comes fairly within the latter predicament must be evident to all who have considered it theoretically or who have had a just experience of it practically. General H. H. Maxwell has for upwards of six years been an energetic and well-judging administrant of these artificial limbs, and in a pamphlet, privately printed, he comes forward as a fully-qualified, impartial witness to their efficacy when duly applied to the proper cases. Having thoroughly schooled himself in the classic treatise on human locomotion by the brothers Weber ("Mechanik des Menschlichen Gehwerkzeugs": Göttingen, 1836), which is quite a sealed book to all but accomplished mathematicians, the General proceeds to show how by minute attention to the requirements of each cripple, above all by careful measurement, and, after trial, by such modifications as may be necessary, the limb can be so fitted, whether to the superior or the inferior stump, as to form a highly serviceable and by no means unsightly substitute for the natural arm or leg. The invention itself was gradual, and, like most things, has reached perfection by successive improvements. Baron Larrey's report on it to the Academy of Medicine in 1851 describes the apparatus as consisting of a piece of ash wood attached like the peg to the ordinary wooden leg. Replacing the metal disc of the peg, it is shaped somewhat like a foot, but shorter in length. The plantar surface is covered with a leathern sole garnished with cork at the heel. It is curved in form, the curve being such as to give the limb continuous lines of bearing on the ground while the body moves forward, save that the curve is not so perfectly uniform as to incur any danger of slipping. Dr. Tillaux, in his report on the Paris Exhibition of 1867, congratulates the inventor on having given the sole of the foot a convex form, which admits of the cripple's raising himself on the stump, while at the same instant he bends the leg to make a step forward, resting on the fore-part of the foot, thus imitating the natural step. In the words of the Count himself as to the action of the curved sole, "a bearing-point in front, acting like the fore-part of the natural foot, is the only means of equalising the pace (of the artificial and natural legs), and of enabling the cripple to get under weigh, as it were, at the beginning of a step with the artificial leg." A further improvement occurred to him in thinking of the poor, who have no money to spend on costly artificial limbs. It was this—to substitute wood for the usual steel uprights of the rich man's leg, and to adapt to it the foot with convex base. Successfully tried under Dr. Broca's superintendence, it was adopted in the civil and military hospitals and by the great charitable societies of Paris, and "at last there was put within the means of fortune's disinherited ones an apparatus which previously only the rich could afford to buy or keep in repair." All this fine philanthropic story is vividly told in the General's pamphlet, and the objections that have been taken to the invention [illegible] and sometimes on the score of [illegible] rebutted. And what has *mutatis mutandis*, be equally said of the Beaufort arm—a not less brilliant triumph of rehabilitating invention. Here, again, General Maxwell's pamphlet successfully removes objections and vindicates theoretically and practically the efficacy of the limb. With the approach of Christmas, his able and kindly treatise might well have public as well as private distribution, if only to give to a wider circle the benefit of its opportune suggestions for the restoration of the crippled breadwinner to his sphere of usefulness.

POLLING THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

IT will be remembered that at the last meeting of the Council of the College of Surgeons it was decided to poll the Fellows, and that the President and Vice-Presidents were requested to draw up a circular, to be addressed to the Fellows to ascertain their opinion as regards (*a*) Members being allowed to vote for Fellows as members of the Council of the College, and (*b*) the admission of Members of the College to seats on the Council. This circular will come before the Council at their next meeting. We congratulate the Council on the concession to the now popular feeling, which this appeal to the Fellows implies. We assume that the terms of the questions submitted will agree substantially with those of the resolutions passed at the general meeting on Nov. 4th. It would perhaps be better if these resolutions were submitted *verbatim*. They were passed by overwhelming majorities at a public meeting called by the Council, and nothing short of what is set forth in these resolutions will satisfy the Members, or be fair to their aims, aspirations, and intentions. The limitations contained in the resolutions materially affect the decision and the ultimate result. The Council should therefore make their circular include all the points at issue. We shall then learn authoritatively how far the Council are in accord with those by whom they are elected to office. If backed by any large majority, their position will be strengthened by the vote; while if the contrary obtains, the Council will be able, with better grace, to give way, and so bring the present deadlock to a satisfactory close.

BARON HUDDLESTON'S STRICTURES ON THE PROFESSION.

"MEDICAL men who gloat over their scientific knowledge and air the same in the witness-box, where they would usurp the functions of the jury without taking a juryman's oath, and excuse themselves by saying they came to get the prisoner off." Such was the scathing denunciation which one of Her Majesty's judges thought fit to level against what it has been our privilege and pride to consider an honourable profession. We are not going to join issue with Baron Huddleston upon the merits or demerits of any particular case or instance of alleged professional shortcomings, but we take exception to the spirit and the substance of his remarks in their more extended application. If from fear, favour, or affection a medical man entered the witness-box with the avowed intention of delivering a prisoner other than with the conviction that he was going to apply his special knowledge to the furtherance of justice, we do not hesitate to say his conduct would merit all that was said by the judge at the late western assize. It is impossible to consider a medical man in the light of an ordinary witness, for he has to explain facts and terms not "understanded of the people," and much of the evidence he gives is inference from observations that he alone is fitted to make. Again, medicine being an inexact science, it is so easy to put several interpretations upon a number of facts which fit the several theories equally well. In the struggle [illegible] arrive at the truth and demonstrate it to a non-scientific [illegible] a medical man is bound in great measure to assume

the position of advocate; but as the late M. Berryer, the inimitable French jurist, remarked, "there is the *fas* and the *nefas* of advocacy." Strictly speaking, it would be well if the medical man could confine his testimony to facts and leave the jury to draw the conclusions; but if this were the custom and practice, the verdicts of juries, founded upon physiological and pathological data, would soon be brought into contempt and placed under the ban of public censure. Faced by these difficulties, medical men can justly claim a wide indulgence if they seem to err or pass the bounds of legal procedure; and we make bold to say that, with rare exceptions, they quickly find a chord of sympathy struck between them and the occupants of the bench and jury-box. If the reports of the recent trials in the west of England can be trusted, it would not be difficult to take up the gauntlet so ruthlessly thrown down by his lordship, and challenge him upon the particular objects of his charge; but we prefer to leave that to the parties more immediately interested, and to take exception to what appears to be a grevious wrong done to the profession at large, unwittingly no doubt, but none the less reprehensible as coming from one clothed in the purity of the judicial ermine. We trust that Baron Huddleston will see his way to disavow the desire to cast obloquy upon a profession which he probably has had reason to consult and trust.

UREA AND ITS RELATION TO CERTAIN MORBID CONDITIONS.

THE question whether urea is furnished equally by all the albuminous constituents of the body, or whether it only represents the decomposition of one particular tissue or organ, has long been a puzzle to physiologists. The exclusive view, however, which regarded urea as derived only from one source, such as from the excess of nitrogenous food taken into the system but not employed, or from disintegration of muscular tissue, or from nitrogenous metabolism taking place in the liver, have given place to wider ones, and most physiologists are now disposed to admit that the sum total of urea eliminated in the twenty-four hours is derived from many sources. Such a belief would enable us to account for many anomalous circumstances attending on urea excretion in disease. Among the many possible sources of urea formation, Dr. Noel Paton (*Journal of Anatomy and Physiology*) has recently drawn attention to the destruction of blood-corpuscles in the liver, under the agency of certain hæmolytic agents, as leading to the increased discharge of urea and urinary pigment. Indeed, these researches have led Dr. Locke, in the *Practitioner* of Sept. 1886, to explain the diuretic action of mercury as exhibited by the action of the preparation known as "Guy's" pill. Dr. Oliver, of Newcastle-on-Tyne, has recently considered the subject from its clinical side, and has arrived at the same conclusion that Dr. Noel Paton has from the experimental—viz., that the destruction of blood-corpuscles forms an important source of urea; and he has shown that in diseased conditions in which chronic anæmia was present the daily discharge of urea was small, but that where the anæmia was quickly progressive the disappearance of blood-cells was always followed by a marked rise in the daily discharge of urea. Also in a paper on Functional Albuminuria communicated to THE LANCET, Oct. 23rd, 1886, Dr. Ralfe observes that the albuminous element of the blood-corpuscles brought to the liver under ordinary circumstances no doubt undergoes transformation into urea; but that when the destruction is considerable, and the process takes place suddenly, probably, whilst there is a decided increase in the formation of urea, a large proportion of this effete albumen is at once got rid of by the kidneys, giving rise to what is known as functional albuminuria. In a more severe form however, the number of blood-corpuscles destroyed great that the conversion of all the effete hæmoglobin into bilirubin cannot be effected, so that a portion of the undestroyed hæmoglobin appears in the urine. In this manner Dr. Ralfe explains the relationship that exists between certain forms of albuminuria and hæmoglobinuria, and the increase of urea elimination that occurs in them. As we have already stated, the belief in the multiple sources of urea enables us to explain many anomalous circumstances attending urea excretion in disease. Thus, for instance, in phthisis with rapid wasting of tissue we should naturally expect a considerable increase of urea elimination if urea were solely derived from tissue metabolism, but no such increase can be definitely established even when high temperature exists; and Dr. Oliver has shown, from the observation of numerous cases, that when the ureal excretion in phthisis is augmented it is always accompanied by distinct evidence of the increase of the anæmia.

THE PERILS OF FOOTBALL.

THE Football Association have issued the following notice:—

"The attention of the Committee of the Football Association having been drawn to the recent numerous accidents at football, arising in some instances from rough and violent play, wish to impress upon all clubs belonging to the Association the necessity for a strict observance of the rules and laws of the game bearing upon the point under the provisions of Rule No. 15. Referees have the power in all cases of 'violent conduct to order the offenders at once to leave the field without any appeal having been made for foul play, and without the previous caution which is necessary in the case of 'ungentlemanly behaviour,' and as it is absolutely essential, both for the safety of players and in the interests of the game, that 'violent play,' easily to be distinguished from fair and legitimate charging, should be put down with a strong hand, the Committee trust that referees will not hesitate to use the power conferred upon them by the rule quoted above whenever occasion may arise."

We are glad to see that the authorities, of the Association game at any rate, recognise that the interests of football are being jeopardised by "violent play," and that accidents occur which are more numerous and severe than need be. We trust that referees will take the strong hint given them by the Committee, and, by using freely their powers, save football from the reproach under which it now labours. If, however, the rules in force are not sufficiently stringent to prevent these frequent and formidable accidents, the Committee of the Football Association must see that they are made so. We should also be glad to hear that the Rugby Football Union is taking steps to minimise the risk of accidents.

FIFTY YEARS' IMPROVEMENTS.

A REVIEW of the sanitary improvements which have been effected in this country during the reign of Queen Victoria was a fitting text for Captain Douglas Galton's address to the Society of Arts at the first meeting of the present session, and the subject was admirably treated by the lecturer. England has indeed undergone a complete transformation during this period, and English people may well remember how much is due to their Sovereign and her beloved Consort for the changes which have been brought about. The England of to-day is widely different from the England of fifty years ago; she has added largely to her possessions, and her influence has been felt in all parts of the world, but the improvements that have taken place have been greatest in the social condition of the people. Captain Galton's address enables all to understand how [illegible] of life fifty years ago. The [illegible] institution of civil regis-

tration of births, marriages, and deaths, and the constitution of the General Board of Health and its successors, have contributed in an untold degree to the happiness and prosperity of the nation. In 1837 it was calculated that one-tenth of the population of Manchester and one-seventh of the population of Liverpool lived in cellars. The window-tax was a cause of excluding the air and shutting out the sun; but in 1851 there was a material advance. Gradually the courts inhabited by the poorer classes in towns were flagged and drained; means were provided for carrying off the waste water which people formerly threw down at their doors; the cleansing of streets and roads was undertaken, and improved water-supplies were provided. Later, health officers were appointed to each district, and its sanitary improvement seriously taken in hand. Captain Galton referred in some detail to the improved condition of the soldier, and reminded his audience that the greatest of the triumphs which had attended the Queen's reign was the saving of millions of lives and the avoidance of a vast amount of physical suffering.

THE LIGHTING OF RAILWAY CARRIAGES.

THIS is a matter of considerable importance, and we are glad to find that it is once again attracting public notice. Railway companies are necessarily monopolists; so far as appearances go, they are doubtless justified in assuming that those who are dependent upon them for the means of rapid travelling must need accept what they please to give. This is, however, but a shortsighted view of the position. As a matter of fact, the regular custom of passengers who "live out of town" and travel daily, or nearly every day, by railway, to and from their places of business, cannot fail to play an important part in the production of profits. And this is the class of passengers which most of all does the useful grumbling against a policy of parsimony and bad management, greatly to the advantage of the general community. Railway directors and administrators who turn a deaf ear to the complainings of these habitual passengers are guilty of singular folly. Looked at from the strictly commercial standpoint, such grievances as this class of customers ventilate are without exception drawbacks to perfect success in earning the largest practicable dividends for shareholders. If it were only possible to make an exact return of the number of families who do *not* live out of town, and whose daily custom is lost to the railway companies by reason of their failure to provide adequate and comfortable accommodation, this view of the case would come quickly home to the financial sense and acumen. We contend that, taking the lowest ground and appealing to the most mercenary and illiberal instinct of railway companies, it would be easy to show that they stand in their own way by not being more amenable to reason in the matter of redressing the wrongs of policy and management which are brought under their notice. Meanwhile there is higher ground that must be occupied. A very considerable amount of actual mischief is done by the long persistent refusal of railway companies to provide suitable means of lighting their carriages. This is a subject on which much has been written, but to very little purpose. The only possible explanation of the great neglect which has been shown in this particular respect is that chairmen and directors have not the courage to incur the needful expenditure. There is, of course, no sort of difficulty in the matter. If only the will existed, plenty of ways and means of attaining the object in view could be found. The Metropolitan and District Companies, not because they are more liberal than others, but because the line lying underground the carriages must needs be lighted, have shown how gas may be employed; and other companies have, by experiment, [illegible] electric apparatus may be [illegible] purposes. It has also been made plain that either gas or the electric light can be economised by being placed under the control of one of the companies' officials, to be turned up when passing through tunnels by day or when it grows dark at night, and turned down again at pleasure. In short, there is no sort of excuse for the failure to provide a proper amount of light for both ordinary and extraordinary purposes. A great mistake was originally made by omitting to provide in the Acts of Parliament which license railway companies that their management should be supervised in every particular and reconsidered throughout, with a view to the public advantage, at short intervals. The supervision which exists is little more than a farce; it is powerless to compel the remedy of evils not directly dangerous to life. This is why so much annoyance and injury is done to passengers in a side way by systematic neglect to meet obvious needs and redress manifest grievances. This is why no inconsiderable part of the public must submit to have its average eyesight impaired, solely because, almost without exception, the railway companies refuse to provide a suitable amount of light in their carriages. It is idle to compare the policy of the several companies in this matter. They are all as parsimonious as the conditions of their enterprise admit. There is nothing whatsoever to be grateful for in relation to any one of the number. Nor have we the least hope that anything we can urge will move them to be reasonable. Our appeal must be to the public, and we would point out that the practice of reading in railway carriages, as for the most part at present lighted, is one that ought to be discontinued. The instances in which injury is inflicted upon persons with weak or irritable eyes are very numerous; and cases of cerebral irritation set up by habitual efforts to read in dimly-lighted carriages are of frequent occurrence. Until the cry for more light elicits a response, it will be simply prudent to abandon the attempt to beguile the time spent in railway journeys by reading. Better do this than sacrifice sight or induce brain disease.

CAUSE OF SPONTANEOUS RUPTURE OF THE HEART.

THE cause of rupture of the heart, which has recently been brought home to the thoughts of the profession in all countries by the case of Professor Panum, has been touched upon by Ziegler, Leyden, Huber, Kraus, and other authors, and has recently been illustrated at the Society of German Practitioners in Prague by Dr. R. v. Limbeck, assistant in Professor Chiari's Institute of Pathological Anatomy, who demonstrated a case which had occurred in the Jewish Hospital, under the care of Dr. Saar. A man, aged seventy-three, who was in the hospital with the signs and symptoms of severe bronchitis, accompanied with fever, but with no indications of cardiac disease, while sitting on the nightstool became suddenly collapsed, and died in ten minutes. The necropsy revealed a rupture of the left ventricle, three centimetres in length, and a remarkable thinning of the wall of the ventricle towards the apex, so that the cavity, instead of being in the form of a cone, was nearly spherical. The muscular substance also was of a dark-brown colour and softened. Evidences of atheroma and calcareous degeneration were found in many of the more important arteries of the body, and when a probe was passed into the left coronary artery from the aorta it was arrested at the depth of a centimetre, the obstruction being, as was found on opening the vessel, complete for half a centimetre. All the coronary vessels were also affected with a considerable amount of endo-arteritis, which in one branch of the left coronary artery had led to a complete blocking up by a thrombus. Dr. v. Limbeck pointed out that Henle and Hyrtl have shown that the coronary arteries [illegible] anastomose with one another, except by means of

capillaries, and so the great softening (fatty degeneration or acute myomalacia), which was found especially in the part of the heart muscle supplied by the obstructed branch of the left coronary artery, is easily explained. The thinning of the heart wall was of course of the nature of a partial heart aneurysm, which, when the extra pressure caused by straining at stool was put upon it, gave way. Ziegler, too, has shown that the anterior wall of the left ventricle is the usual seat of rupture of the heart, which may very probably be due to myomalacia consequent on sclerosis of the coronary artery, which has been itself caused by thrombosis or embolism.

THE OFFICE OF CORONER FOR EAST MIDDLESEX.

THE proposal that the district apportioned to the coroner for East Middlesex shall be divided recalls the time when the founder of this journal, the late Mr. Thomas Wakley, M.P. for Finsbury, as well as coroner for Middlesex, did the duty of the whole western division of the county, and did it well. Of course, the population has greatly increased since his day, but it is difficult to believe that this fact can wholly explain the multiplication of inquests. We cannot, of course, presume to account for the altered condition of affairs, but it may be permissible to offer one obvious suggestion—namely, whether the need for a largely increased and increasing number of inquests is not, in part at least, due to the fact that, as a rule, the issue of an inquiry is not productive of any decisive result. It must be manifest that if nothing comes of the misconduct or neglect of those who provide the subject matters of inquests, the number of these inquiries is likely to increase. Practically, we fear, the knowledge that an inquest now commonly amounts to nothing more than a formal proceeding, by which the county obtains a satisfactory knowledge of the cause of death at the public expense, induces those formerly in the habit of sending for medical advice, "for the sake of a certificate," to let matters take their course. The propottion of cases in which neglect to call in a medical practitioner is the sole or principal cause of the need for a coroner's inquest is very large. Genuine cases of doubt or mystery of course increase with the population; but cases of neglect to seek medical advice increase in greater ratio. Another source of increase in the number of inquests is to be recognised in the multiplication of institutions which give medical advice with very little discrimination, so that, practically, the victims of heart, and lung, and brain, and organic diseases generally, are not expected to place themselves under responsible medical treatment, and when dying suddenly, as they are likely to do, inquests are required to determine the cause of death.

MICRO-ORGANISMS IN ACUTE RHEUMATISM.

DR. PAUL GUTTMANN records a case (*Deutsch. Med. Woch.*, No. 46) which he thinks has some bearing upon the etiology of acute rheumatism. The case was that of a lad fourteen years of age, who was admitted into hospital with well-marked symptoms of the disease. Pericarditis supervened, and owing to the rapidly extending effusion paracentesis of the pericardium was practised; only a small quantity of purulent fluid was obtained, but after death, which shortly ensued, the sac was found to be distended with pus and fibrin. There were also numerous abscesses in the kidneys; but the effusion in a knee-joint which was examined contained the usual sero-fibrinous exudation, and no pus. Microscopical examination of the pus and exudate showed micrococci in abundance (staphylococcus pyogenes aureus), and gelatine cultures were readily obtained. Dr. Guttmann had little doubt that this microbe, which was found in the joint effusion as well as in the pericardial and renal pus, bore an etiological relation to the disease in this instance, and suggests that other forms may be found in other cases. Micrococci have been found in pericarditis by other observers, and the experimental production of endocarditis by Orth, Ribbert, and others, by means of the intravenous injection of cocci, is one of the most interesting of recent contributions to pathology. Acute rheumatism, again, has many analogies with specific infective diseases, as was shown at the Brighton meeting of the British Medical Association by Dr. Mantle, who also described the discovery he had made of micrococci in the blood in this disease.

METROPOLITAN ASYLUMS BOARD: CLINICAL INSTRUCTION.

THE Committee of the Eastern Fever Hospital of the Metropolitan Asylums Board have appointed Mr. Reginald Dudfield, B.A., L.R.C.P., M.R.C.S., of Upper Phillimore-place, Kensington, to be junior assistant medical officer at the hospital for a limited period. This is the first appointment made in carrying into effect the resolution of the managers to make their small-pox and fever hospitals available for clinical instruction in infectious disease for the benefit of registered medical men whose opportunities for observing this class of diseases have been curtailed almost to the point of extinction by the closure of general hospitals against patients suffering from small-pox, typhus fever, scarlet fever, and, in a less degree, enteric fever. The Local Government Board recently gave their sanction to the principle involved in Mr. Dudfield's appointment. The gentlemen thus appointed will be entitled "assistant medical officers." They will have specified duties, and be in all respects subject to the regulations in force with regard to the hospitals. The remuneration of the office is limited to the allowance of residence, rations, &c.

CHOLERA IN EUROPE.

THE recurrence of cholera in fresh localities in Eastern and Central Europe is the most striking feature of the present phase of this year's epidemic. Large outbreaks are hardly to be expected in Europe at this season of the year, but it is most disquieting to learn that in certain parts of Austrian and Turkish Croatia, and in some districts of Hungary, fresh places are being attacked. The disease has also taken a fresh stride in a south-eastern direction, Belgrade having been attacked. According to the latest intelligence, cholera broke out in one of the infantry barracks, and between the 21st and 27th of November there had been fifty cases and ten deaths. The King of Servia, on receiving the intelligence, returned to his capital and personally visited the sick; he at the same time stimulated the authorities to take ample precautions to prevent the spread of the disease. Typhus is also prevalent in Belgrade, so that there is doubtless ample room for sanitary progress.

AIDED EMIGRATION OF PAUPER CHILDREN.

AMONG various questions relating to the poorer population, not the least important is that which affects the future of pauper children. What is to be done with them? Shall they grow up under the guardianship of the parochial system to find what occupation they can in an overcrowded market, and perhaps to be ultimately absorbed in the ranks of the idle and criminal classes, or is there any course which offers them a surer hope of future usefulness? This question cannot yet perhaps be answered in the affirmative, but there is reason to believe that it may be so answered under a system of aided emigration. A recent writer assures us that many of the children who now burden the parish [illegible] alone or as the inmates of [illegible]red to the colonies to

the advantage of the latter, at a cost under that of their annual maintenance at home. There are distinct advantages in such a scheme if it could be satisfactorily carried out. On the one hand, children at an age when they are still impressionable for good or evil are removed from the damaging influence of early associations; on the other, they take a fresh start in life in a new country, where, if inclined to work, they will be welcome, and will have every opportunity and encouragement to use their energies. Many will equally gain in physique by leaving behind them at a critical age the unhealthy slums in which they were reared, and taking up out-door occupations in their adopted country. The experiment has already been tried, and so far, we learn, with success.

THE HOSPITAL SUNDAY FUND.

THE Council of the Hospital Sunday Fund, on Monday last, agreed on their report to the meeting of the constituents, which is to be held in the Mansion House in December. The special exertions of this year have resulted in a collection of £40,399 7*s.* 1*d.*, as compared with £34,320 8*s.* 5*d.* in 1885, and an average of £30,121 6*s.* 8*d.* in the preceding thirteen years. The legacy of £1000 by the late Dr. Wakley was gratefully acknowledged by the Council. A proposal to invest that sum was with much unanimity discouraged by the meeting. Sir Sydney Waterlow led the objection to it by strongly expressing the view that we must not burden ourselves with the anxieties of those who have to come after us, but with pressing urgencies of the present. It was resolved to recommend for election on the Council, the Earl of Strafford, Sir Andrew Clark, Mr. Alderman De Keyser, Mr. R. Foster, Mr. Wakley, Mr. Lionel Cohen, M.P., the Rev. Prebendary Eyton, the Rev. C. J. Ridgway, the Rev. Dr. Clifford, and the Rev. J. R. Wood, to fill the vacancies which have recently occurred in its numbers. Benevolent persons who wish to benefit hospitals either during life or after their death cannot do better than make the Hospital Sunday Fund the almoner of their charity. Money distributed through them would go straight, and with only the slightest abatement in the way of expenses, to the most needy and meritorious charities. There is no fund administered so economically as that of the Hospital Sunday Fund. During the past year the extraordinary steps taken to increase the fund have made the working expenses a little more, but even so, they only amount to 3·942 per cent. of the gross receipts.

VEGETABLE OR MIXED DIET.

THE question of preference between animal, vegetable, and mixed foods is constantly recurring, and will probably continue to present itself for a long time to come. This is the more likely, since it is one of those questions the answer to which will greatly vary in the case of different individuals. The purely animal diet need hardly now be considered, since it is probably unknown in this country. The same cannot be said of the vegetarian system. A restaurant recently opened in the Strand by Messrs. Spiers and Pond, and another called the "Orange Tree" near Charing-cross, on the tables of which meat is not found, are sufficient to testify that London, at all events, is inclined to give a trial to light fare. There is, undoubtedly, much to be said in favour of this kind of nourishment. The results of the penny or halfpenny dinner supplied to school-children afford proof of its power to sustain and increase in the young both physical and mental strength. Similarly, there are adults whose constitutions are on the whole better suited for assimilating herbs or farinaceous food than meat. Such, for example, are the [illegible] restrict themselves to a [illegible] health. Again, there are many persons who have no such constitutional difficulty to consider who might with advantage at least reduce their daily consumption of animal food. Three or four meals a day at which meat is taken cannot constitute the rule of wholesome living for any but a small and active part of civilised mankind, though this does not imply that a total absence of meat is rather to be advised. For the great majority of healthy people we should certainly recommend a mixed diet in preference to any other, though a vegetable meal now and then will afford a change of fare at once nutritious and palatable.

THE PUBLIC HEALTH ACT, 1875.

THE Birmingham Corporation has always deserved to be considered one of the more advanced of English sanitary authorities. It has now, under the advice of its health officer, the president of the Society of Medical Officers of Health, proceeded against a landlord who refused to abate a nuisance on the ground that there was a tenant in possession, and that he could not properly enter the premises except for certain reasons specified. This case was heard on appeal before Mr. Justice Cave and Baron Pollock, who decided that the landlord was liable to do the work, being the owner within the meaning of the 94th section of the Public Health Act. If he had shown under Section 93 that he had used all due diligence to carry out the order, he would not have been liable for any penalties, but this he had omitted to do. The decision of the Court was therefore against him, Mr. Justice Cave observing that it would be hard on an occupier if he had to make good structural defects which arose from the neglect of the owner; while Baron Pollock wisely pointed out that "it is not probable that the tenant in the majority of instances would object to his landlord coming on the premises to abate a nuisance which was injurious to the health of the persons living there." This decision will doubtless reduce the difficulties sanitary authorities have to meet at the hands of obstructive landlords, and tenants will be encouraged to seek the aid of their local board when they have reasonable ground for complaint. It deserves, therefore, to be widely circulated.

THE FIRST EXCISION OF THE SPLEEN IN SPAIN.

SENOR DON DR. RIDERA recently performed excision of the spleen on a boy of ten in the Hospital del Niño Jesus in Madrid. This is the first time the operation has been performed in Spain, and unfortunately was followed by a fatal result the next day from shock. Immediately after the operation syncope came on, and it was with considerable difficulty that the child was revived. It was remarked that the operating theatre, although in one of the most important hospitals in the Spanish metropolis, was badly lighted, and unprovided with a subcutaneous syringe for injecting ether or with a faradisation instrument.

PROSTITUTION IN LIVERPOOL.

MR. FREDERICK W. LOWNDES of Liverpool has published a pamphlet, to be had of Messrs. Churchill, on the subject of Prostitution and Venereal Diseases in Liverpool. Mr. Lowndes' position as surgeon to the police force of Liverpool and the Lock Hospital gives importance to his views on this painful subject. He estimates that there are at least 4000 prostitutes plying their trade within the city, without let or hindrance, however diseased they may be, so long as they are not guilty of flagrantly disorderly conduct in the streets. One of the most interesting parts of his paper is that in which he discusses the causes of prostitution:—1. Those relating to men—(*a*) juvenile precocity; [illegible] the large number of young men in Liverpool marriage-

able but unmarried, thousands living a life of enforced celibacy; (*c*) men able to marry, but unwilling; (*d*) intemperance. 2. Those relating to women—(*a*) want of parental control; (*b*) seduction; (*c*) love of dress and finery; (*d*) bad arrangements in domestic service; (*e*) immoral female characters in large factories where girls are employed. The latter part of Mr. Lowndes' paper is devoted to an account of the laws for controlling prostitution, which are very ineffective. He ends by quoting Sir William Jenner, which should be studied by all young men and by public authorities. But there is a terrible continuity and persistence in this vice.

SIR JAMES PAGET ON SENTIMENT.

AT a luncheon held in St. Bartholomew's Hospital a few days ago, to celebrate the reopening of St. Bartholomew's Church, Sir James Paget gave utterance to a manly and practical view of the question of sentiment as a source or spring of action. We are too much inclined to despise or undervalue sentiment in this day of pretentious realism and affected precision. It is well that great and trusted scientists, whose words must needs have weight with the whole profession, should be both able and willing to speak out on this topic. We wish the speech of Sir James Paget had been reported in full. Meanwhile one sentence is worth preserving, and might well form the text of a sermon addressed to those who seem to think that because science claims to rest on facts, such fancies as supply the material of sentiment must needs be disregarded. This is a fallacy that cannot be too frequently or forcibly exposed.

THE HARVARD CELEBRATION.

THE 250th anniversary of Harvard College was celebrated on Nov. 5th and three following days. On the 5th there was a reunion of the *alumni* of the Law School, at which Mr. Justice Oliver Wendell Holmes, jun., delivered an oration. The second day was celebrated by the undergraduates; and on Sunday, the 7th (the actual anniversary of the foundation), memorial services were held in the College chapel. The final day, or "Graduates Day," was occupied by a meeting in the morning in the College theatre, when an oration was delivered by the Hon. Jas. Russell Lowell, and a poem by Dr. Oliver Wendell Holmes. The honorary degree of LL.D. was conferred upon the following three distinguished members of the medical profession—viz., Dr. Leidy of the University of Pennsylvania, Dr. S. Weir Mitchell of Philadelphia, and Dr. J. S. Billings of Washington. The President of the United States was present on this occasion, and also at the banquet which was held in the afternoon. A torchlight procession of the students closed the day's proceedings. The *Boston Medical and Surgical Journal*, from which we quote, urges the propriety of starting an association of medical *alumni* of the University, the Medical School being almost the oldest and largest department.

THE VACANT CORONERSHIP.

THE Middlesex magistrates have decided to present a petition to Her Majesty, praying that the eastern district of the county, as constituted by Order in Council made in 1862 for the purpose of an Act to amend the law respecting the office of county coroner, be altered or divided. The chairman stated that the new coroner would have to confer with the Court as to the salary, and that he certainly would not be elected at the salary which the late coroner received. In addition to the candidates for the vacant office mentioned in our last issue, the following have announced their intention of competing for the coronership: Mr. Cresswell Hewett, M.R.C.S., Mr. W. E. Baxter, and Mr. Thomas Beard.

THE HOUSE OF INDUSTRY HOSPITAL, BOSTON.

THE current number of the New York *Sanitary Engineer* gives plans and descriptions of the new hospital, on the pavilion type, which has been erected for the House of Industry at Deer Island, near Boston. It consists of four one-storeyed pavilions united by a corridor, with a kitchen and administrative block near to the centre of the buildings. The pavilions are on tressels, and their floorings are 4 ft. from the ground; each pavilion is 128 ft. long and 28 ft. wide, with an average height of 18 ft. Each pavilion has the public ward near the middle of its length. The public ward is approached through a group of ward offices and at the far end of each pavilion are isolation wards. The waterclosets are in projecting turrets. There is nothing very novel in all this. We are told that the air-space per bed is about 1500 cubic feet. This means that, with an average height of 18 ft. and a width of 28 ft., each bed has only 84 square feet of floor space, and that there is barely 3 ft. between the beds. This is far too little, and the architect would have done well to have reduced the height of the pavilions and have given more area per patient. The buildings are entirely of timber, and are heated by hot-water coils. In the winter there is provided a complete arrangement for artificial ventilation; a series of air-ducts in the floor terminate in an exhaust flue at one end, which is heated by a steam coil. We are told that the buildings cost $60,000, or £12,000. One pavilion of the four is still wanting, so that there is now accommodation for about 100 out of the full complement of 134 patients. This makes the cost per bed about £120, a very moderate sum; but it must be remembered that the building is entirely of wood, and not to be compared with solid structures of brick or stone.

THE STATE EXAMINATION AND THE DIFFERENT PRUSSIAN UNIVERSITIES.

IN looking over the summary of the results of the Prussian State examinations for diplomas during the last year (which we briefly noticed in our impression of the 20th ult.), one is struck by the good performances of the candidates from some of the smaller universities. While Berlin sent up 203 candidates, 55 of whom had previously been rejected, passing 1 in the first class (very good), 76 in the second (good), and 50 in the third (sufficient), Bonn sent up 47 men, only 2 of whom had been previously rejected, passing 4 in the first class, 29 in the second, and 8 in the third; and Konigsberg, with 2 rejected and 33 new candidates, achieved 6 first classes, 15 second, and 3 third. The plucking seems to have been most severe in Halle, Konigsberg, and Berlin, where about a third of the men failed. In Kiel the proportion of failures was about 1 in 7, and in Bonn only 1 in 8.

VALUE OF MEDICAL EVIDENCE IN LIFE INSURANCE.

THE *Scottish Banking and Insurance Magazine* of Nov. 5th contains an able article on the "Apportionment of Premium to Risk in Cases of Life Insurance." The object of the author is to refute the views of Mr. Chisholm, a Fellow of the Institute of Actuaries, and manager and actuary of a life insurance company, who in a paper before the Institute had expressed himself as being rather doubtful of the advantage of medical estimates of the value of life for insurance purposes. Mr. Chisholm says that in the olden days irregularity of the heart and albuminuria were never discovered. But he does not think the offices were much worse off in consequence, because in his estimation these maladies were probably only transient. It is curious to see a man of importance and intelligence writing so in these days. [illegible] answered in the paper before us [illegible] competition in life insurance

business and the consequent low rates on which it is done make care and every kind of precaution against bad lives essential. The question is not whether too much importance may not be occasionally attached to a medical symptom or a physical sign, but whether intelligent medical evidence is better dispensed with. Be it that such symptoms as Mr. Chisholm mentions are occasionally temporary and unimportant, who is to decide in any given case in which they exist whether they are so or not? The discussion at Brighton on this very subject showed how judicial good medical opinion is even in regard to grave physical signs, and how much disposition there is to give due credit to all qualifications of them. Mr. Chisholm's views are only tenable on the supposition that medical men are deficient in common sense and that directors have more than their share, which may be an excusable theory in the actuary of an insurance office, but will not commend itself to ordinary people. It would be strange indeed if all the improvements in the diagnostic and therapeutic departments of medicine had no value for insurance purposes. We commend the article in our contemporary to our readers and all concerned.

THE FORTHCOMING LECTURES AT THE COLLEGE OF PHYSICIANS.

THE following arrangements have been made in respect of the above lectures for 1887. The Gulstonian will be delivered on March 3rd, 8th, and 10th, by Dr. Macalister of Cambridge, his subject being "The Nature of Fever"; the Croonian will follow on the 15th, 17th, and 22nd of the same month, and will be given by Dr. Broadbent, who will discourse on "The Pulse"; on March 24th, 29th, and 31st the Lumleian lectures will be delivered by Dr. Priestley, who will take for his subject the "Pathology of Intra-uterine Death."

LEGACIES TO HOSPITALS.

THE will of a man like Mr. Morley, at once wealthy and benevolent in a high degree, is a matter of much public interest, and might without disrespect be made the subject of a little criticism. From our point of view it has one great defect—it does not leave anything to hospitals. We believe that hospitals have a peculiar claim on such accumulations of money as that so creditably associated with Mr. Morley. If they are not to be built and endowed out of such accumulations, it is difficult to see much prospect of relief for them in their present impecunious position. Of course it will be said that Mr. Morley did what he thought fit for hospitals while he lived, and few men were more entitled to claim the right to do what he pleased with his own; but, even so, we may express disappointment that about half a million of money can be bequeathed by one so intimately and honourably associated with hospital funds without mention of such institutions.

MILK POLLUTION.

AN interesting case has been heard at the Guildhall showing the possibilities of pollution of milk from noxious chemical effluvia. The defendant was summoned at the instance of the Commissioners of Sewers in the City for carrying on a chemical process which was dangerous to the public health. Complaints had been made to the medical officer of health by a milk-seller who carried on business on the ground-floor of the premises of which the defendant occupied the basement, the complainant stating that the milk was injured by some effluvia arising from the lower part of the house. Dr. Sedgwick Saunders gave evidence that he visited the premises a[illegible] distinct metallic effluvium emanating fro[illegible] chemical testing, he was under the impression that it consisted of nitrous acid gas, which was suffocating and poisonous; the milk would absorb the effluvium and thus become dangerous to the drinkers. Alderman Knill, before whom the case was heard, inflicted the full penalty of £5 and 2s. cost. No notice of appeal appears to have been given.

THE FRENCH MILITARY MEDICAL SERVICE.

THE number of admissions into the French Military Medical School of Val-de-Grace has this year been much fewer than usual. As a rule sixty-one students who have completed two years' medical study are admitted. This time, however, only twelve have been accepted. This is not, it appears, due to any existing surplus of military surgeons, for, in fact, the medical department of the army is by no means complete as regards its *personnel*. The reason is to be looked for in the necessity for economy. Indeed, it has been suggested that the school of Val-de-Grace itself may have to be abolished. Sudden changes are of course highly inconvenient to intending candidates, and a petition to the Minister of War is being prepared requesting that the number of vacancies to be filled should always be announced some time in advance.

DR. WATERS AND THE CHEMISTS OF CHESTER.

THE chemists of Chester have presented an address of congratulation to Dr. Waters on the presentation of the gold medal by the British Medical Association, and the presentation of his portrait by the public of Chester. We congratulate Dr. Waters. He knows our sentiments. He deserves great credit for years of trouble to obtain medical reform, though at the last he suffered himself to take too limited a view of the whole subject, and to accept an Act which, on the admission of the President of the Medical Council, withholds the chief reform, and may yet give much trouble to the profession.

THE EXAMINATION OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE first examination for the certificate in Psychological Medicine, conducted by Drs. Hack Tuke and Savage, was held on Nov. 29th and 30th. The written examination included questions on Classifications and Symptoms, on the forms of Mental Disease associated with Epilepsy, on Testamentary Capacity, the Treatment of Acute Mania, and on Statutory Forms relating to Admission. The practical part included examination of patients, filling up and correction of certificates, &c.

RECENT HONOURS.

THE Queen has given orders for the appointment of Deputy Surgeon-General John M'Neale Donnelly, M.D., of the Indian Medical Department, to be an Ordinary Member of the Military Division of the Third Class, or Companion of the Order of the Bath. Her Majesty has also been pleased to confer upon Deputy Surgeon-General Stewart Aaron Lithgow, C.B., M.D., of the Army Medical Staff, for action at Giniss, the distinction of Companion of the Distinguished Service Order.

TYPHOID FEVER IN PORTH.

THERE is an outbreak of typhoid fever in Porth within the local board district of Ystradyfodwg, the prevalence being associated with conditions of excrement disposal and drainage, which are locally described as a disgrace to any civilised nation. It is alleged that the attention of the sanitary officers has been called to the matter, but that nothing has yet been done by way of remedy. We trust the matter will receive prompt attention.

THE GENERAL HOSPITAL IN JERSEY.

WE regret to say that the opportunity occasioned by the lamented death of Dr. Charles Godfray, of Jersey, has not been used for improving the medical service of the General Hospital at Jersey. The arguments for enlarging the staff were unanswerable, but they have not prevailed. Another one-man appointment has been made. The fortunate gentleman is Mr. Walter Falla. We do not doubt the fitness of Mr. Falla to stand in the succession to Jones and Godfray, though his oldest qualification only goes back to 1879. We may admit, too, the force of much of the good-natured banter in which the *Chronique de Jersey* indulges with regard to the abounding and superlative testimonials of his fellow-candidates for the post. But for all that, we think that the principal, and till lately the only, hospital in Jersey ought to be served by a larger and more varied staff. A little competition in hospital is good for a community isolated as that of Jersey is, and remote from great hospital centres.

MR. FURNEAUX JORDAN.

OUR readers will learn with regret that Mr. Furneaux Jordan, Senior Surgeon to Queen's Hospital, co-Professor of Surgery at Queen's College, Birmingham, &c., has recently resigned his many surgical appointments, and that the state of his health compels him to retire altogether from professional life. His friends and old pupils intend giving him a substantial testimonial in recognition of his many contributions to the science of surgery, and of his services to the profession. Mr. Bennett May and Mr. Jordan Lloyd are acting as honorary secretaries, *pro tem.*, to the testimonial fund, which we hope will prove worthy of Mr. Jordan's acceptance.

ANOTHER SENSIBLE JUDGMENT.

DR. EDIS, as "the other certifying doctor," has been sued for his share of the responsibility in placing a lunatic in an asylum. The case was complementary to one on which we quite recently commented. In this instance Baron Pollock ruled that the defendant was within the protection of the Act, and directed a verdict for him, and gave judgment accordingly. These sensible procedures will do much to relieve the tension which exists in relation to the working of the Lunacy Laws, which afford very little security to the doctors, particularly as they have been of late years set in motion by suitors and judicially administered.

EPIDEMIOLOGICAL SOCIETY.

AT the next meeting of this Society, which will be held at 11, Chandos-street, W., on Wednesday next at 8 P.M., Dr. J. Edward Squire will read a paper on "Typho-malarial Fever." It is expected that the paper, and the discussion it will elicit, will be of much interest. Dr. Squire has recently studied this subject at Suakim, and it is hoped that others with special experience of the disease will take part in the debate.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Professor Gerhardt celebrated his twenty-five years' jubilee on the 9th ult.

Cracow.—Dr. Lazarski, Extraordinary Professor, has been appointed Professor of Pharmacology.

Dorpat.—Dr. Carl Dehio has been appointed Extraordinary Professor of Special Pathology and Therapeutics.

Greifswald.—Dr. Grohé, Professor of Pathological Anatomy, who had been made a Privy Councillor, did not live to enjoy his new honours, his death having occurred on Nov. 21st, in the fifty-seventh year of his age. In 1858 he was first appointed to Greifswald, and in 1862 received the full professorship. He is best known for his researches in pathological chemistry, especially upon the occurrence of glycogen in the lungs and heart, and more recently he studied the subject of the effects of intravenous injection of pathogenic fungi, in which he was followed by Dr. Grawitz, who is likely (*Berl. Klin. Woch.* No. 48) to succeed him in the professoriate.

Marburg.—Professor Maunkopff, Director of the Medical Clinic, has been made a Privy Councillor.

Munich.—Dr. Gietl, though improved in health, being still unable to give clinical instruction, Professor Bauer will for the present session take charge of the first medical section of the City Hospital.

Paris.—M. Béclard, Professor of Physiology, has been nominated Dean of the Faculty of Medicine for a fresh period of five years.

Prague (German University).—An invitation having been given to Professor Heubner of Leipsig, to a chair of Diseases of Children in Prague, and the Saxon Government being unwilling to make the arrangements required by Professor Heubner as the condition of his remaining at Leipsig, he has decided to accept the call and go to Prague. It is stated that in case of his refusal Dr. Escherich of Munich, would have been invited.—Dr. Wilhelm Fischl has been appointed to act for Professor Bandl, who is ill.

Würzburg.—The two names proposed by the Medical Faculty for the vacancy caused by the removal of Professor Grashey to Munich are those of Dr. Jolly of Strasburg and Dr. Krieger. (Dr. Jolly is the son of the late physicist of that name, of Munich.)

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of October it appears that the Thames water sent out by the Chelsea and West Middlesex companies again contained the very small proportion of organic matter which characterised the samples during the previous three months; whilst the supplies of the Southwark, Grand Junction, and Lambeth companies exhibited a noticeable increase in this respect, although the proportion was by no means excessive for the time of the year. The water drawn from the Lea and distributed by the New River and East London companies manifested no change since the September samples were taken, the proportion of organic matter present being exceptionally small. All the waters were clear and bright on delivery.

DR. WILLIAM TINDAL ROBERTSON, who on the 29th ult. was elected member of Parliament for Brighton, received his professional education at University College Hospital. He became a licentiate of the Apothecaries' Society in 1848, a member of the Royal College of Surgeons of England in 1850, and in 1853 obtained the degree of M.D. at the University of Edinburgh. In 1854 he commenced practice at Nottingham, remaining there until failing sight, which has since culminated in total blindness, compelled him to retire in 1875. Since that date Dr. Robertson has resided at Brighton, and taken an active part in the political life of the town.

IT is authoritatively stated that the Senate of University College, London, has not taken any definite action towards enrolling the College as a constituent part of Victoria University, and that the question of such enrolment has not even been broached at the meetings of the Council.

A BARQUE arrived off Dover on the 27th ult. from the West Indies, and was placed in quarantine, having yellow fever on board. The vessel was not

AT the meeting of the Branch Medical Council for England held on Friday last, resolutions were passed by the Council recording their sense of the judicious care and management with which the details of the late election of direct representatives on the General Medical Council had been conducted by their Registrar, Mr. Millar, and an Honorarium of £50 was presented to him.

THE Grand Cross of Isabel the Catholic has been conferred on Señor Don Dr. Matías Nieto Serrano, editor of *El Siglo Médico*, the leading Spanish medical weekly.

THE new pathological institute at Bonn was opened on Oct. 30th, with appropriate ceremony. It is said to be the finest of its kind in existence.

THE ELECTION OF DIRECT REPRESENTATIVES.

THE following are the numbers of votes polled by the respective candidates last week at the election to the General Council.

Number of voting papers sent out in England ...	18,074
Number of voting papers returned from England	13,381
Wheelhouse, Claudius Galen, F.R.C.S. Eng., Leeds ...	8548
Foster, Sir Balthazar Walter, F.R.C.P.L., Birmingham	7718
Glover, James Grey, M.D. Edin., London	6614
Richardson, Benjamin Ward, M.D. St. And., London ...	4704
Dolan, Thomas Michael, M.D. Durh., Halifax, Yorkshire	3063
James, Moses Prosser, M.D. St. And., London	1223
Morris, Edwin, M.D. St. And., Spalding	986
Balding, Daniel Barley, F.R.C.S. Eng., Royston	896
Taaffe, Rickard Patrick Burke, M.D. Lond., Brighton	878
Brown, George, M.R.C.S., L.S.A., London	865
Carpenter, Robert Henry Spencer, L.R.C.P.L., London	731
Bullock, Henry, F.R.C.S. Eng., Isleworth	463
O'Connor, Bernard, M.D. Q.U.I., London	320
Watts, Algernon Newbegin, M.R.C.S., Sharnbrook ...	214

In consequence of many of the voting papers having been carelessly filled in, a considerable number were invalid.

Result of Poll for Scotland.		*Result of Poll for Ireland.*	
Dr. Bruce	642	Dr. Kidd	911
Dr. Morton	596	Dr. Jacob	614
Dr. Sinclair	414	Mr. Laffan	195
		Dr. McMordie	161

DR. GLOVER'S ELECTION.

A MEETING of Dr. Glover's Executive Committee was held at the residence of Sir Andrew Clark, Bart., on Tuesday evening last. There were present, Dr. Stokes (chairman), Sir A. Clark, Dr. James Anderson, Dr. Glover, Mr. Shirley Murphy, Mr. Pearce Gould, Mr. Anderson Critchett, Mr. Lough, and Mr. Keele and Mr. Fraser Stokes (hon. secs.)

Dr. STOKES, in intimating formally the result of the election, congratulated both Dr. Glover and the committee on the event, as it gave Dr. Glover the important and honourable position for which he had been a candidate, and it brought to the committee the satisfaction of having secured the return of a representative who knew his duties as a member of Council, and who, he felt sure, would perform those duties ably and well.

Dr. GLOVER thanked his committee, each and everyone, for their kind exertions on his behalf. To them and to his many supporters throughout England and Wales he owed his success—a success which had been gained in a way and by means that would bear scrutiny. Some of his supporters did not agree with him upon all points, but he trusted that by honest thought, consideration and [illegible] they would be able to reach [illegible]

points in his election on which he thought they might be congratulated were, that the freedom of the profession had been rigidly respected, that he had frankly indicated his own opinions on difficult subjects, and that the election had been conducted on quiet and inexpensive lines.

It was unanimously resolved that no part of the expense of the election should fall on Dr. Glover, but that it should be borne by his committee, and it was arranged that subscriptions for this purpose should be sent to Mr. G. T. Keele, 81, St. Paul's-road, Highbury, by whom they will be acknowledged.

Dr. GLOVER moved a vote of thanks to the chairman of his committee, Dr. Stokes, and to the hon. secs., Mr. G. T. Keele, Dr. Reid, and Mr. Fraser Stokes. He said that it had been a peculiar gratification to him that these important offices had been filled by his near neighbours, and had it not been for the support he had received from practitioners in his own immediate neighbourhood he should not have consented to come forward for such a post.

The resolution was cordially seconded by Sir Andrew Clark, who referred to Dr. Stokes as an exemplary chairman, than whom he had never seen a better. The resolution was unanimously carried, and a similar one, thanking Sir Andrew Clark for the energetic assistance he had given throughout the election, brought the proceedings to a close.

WILLS OF MEDICAL MEN.

THE will of Charles Chadwick, M.D., late of Broadwater Down, Tunbridge Wells, Sussex, who died on Aug. 30th last at Buxton, was proved on Nov. 1st by Mr. John Stone Wigg, the Rev. John Watkins, and Charles Montagu Chadwick, physician, the son, the value of the personal estate amounting to upwards of £92,000. The testator bequeaths £500, besides some furniture and effects, to each of his unmarried daughters; and his plate is to be divided between his children. The residue of his real and personal estate he leaves in equal shares to, or upon trust for, his nine children; but the amounts settled upon his unmarried daughters, and the amount advanced to one of his sons, are to be taken into account in the division.

The will of Henry Jewell, M.D., formerly of Sidmouth, but late of Salcombe Regis, Devon, who died on Aug. 27th last, was proved at the Exeter district registry on Oct. 18th, by Captain Edward Hennale, R.N., and Mr. Henry Whitworth Andrew, the executors, the value of the personal estate amounting to upwards of £8000. The testator bequeaths £100, and his plate, books, pictures, household furniture, and effects, to his wife, Mrs. Kate Jewell; an annuity to his sister, and legacies to his executors. The residue of his real and personal estate he leaves upon trust for his wife for life or widowhood, and then for his grandson, Edward Jewell Whitting.

The will of Mr. Francis Falwasser, Surgeon-Major, Medical Staff Corps, late of the North Camp, Aldershot, Hants, who died on Feb. 4th last in India, was proved on Oct. 27th, by Colonel Francis Duncan, R.A, C.B., and Mr. Ernest Bateman Falwasser, the brother, the executors, the value of the personal estate amounting to upwards of £4000. The testator, after making some specific bequests to his brothers and sister, gives his furniture and effects to Mrs. Julia Alicia Madeline Murphy for life, and then for her three daughters. The residue of his property he leaves upon trust for Mrs. Murphy for life, then for the maintenance of her daughters under twenty-one, and ultimately for the daughters of his brother, the Rev. John Frederick Falwasser.

The will and two codicils of Robert Fowler, M.D, late of 145, Bishopsgate-street Without, and 12, Old Burlington-street, who died on Aug. 7th last at Hampstead-heath, were proved on Nov. 6th by Walter Fowler, R.M., F.R.C.S, the son, and Charles Jeken Elwin, the executors, the value of the personal estate exceeding £4000. The testator gives £100 and the lease of his residence in Old Burlington-street, with the furniture and effects, to his wife, Mrs. Judith Fowler, certain property in Shropshire to his said son, and other legacies. There are also some specific gifts of presentation plate to children. The residue of his real and personal estate he leaves to his three children, Walter, Harriet, and Margaret, in equal shares.

The will and codicil of Harvey Buchanan Holl, M.D., late

of 1, Derby Villas, Cheltenham, who died in September last, were proved on Oct. 11th by Mr. William Haworth Holl, the brother, and John Lawrance Longstaffe, the executors, the value of the personal estate exceeding £3700. The testator bequeaths the silver inkstand presented to him by the governors of York Hospital to his said brother. The remainder of the provisions of the will are in favour of his brother, and of Bennit Mason, Harvey Mason, and Annie Mason.

The will, with two codicils, of Walter Somerville, M.D., formerly of Greenfield, county Lanark, N.B., but late of Harrogate, who died on May 28th last, was proved on Oct. 26th by Mrs. Isabella Young Somerville, the widow, John McCasland McCulloch, and George Dalziel, three of the executors, the value of the personal estate in the United Kingdom amounting to over £2000. The testator gives an annuity of £60, to be subsequently increased to £1000, charged on his estate at Greenfield, to his wife; and the residue of his property equally among his children.

The will of Cosmo Gordon Logie, M.D., F.R.S.E., late of 47, Queensborough-terrace, Bayswater, who died on April 6th last, was proved on Oct. 11th by Mrs. Maria Logie, the widow and sole executrix, to whom he gives all his estate and effects.

The will and two codicils of George Miller, M.D, late of 6, Beaumont Villas, Spring-grove, Isleworth, who died on Aug. 31st last, were proved on Nov. 5th by William Hine Haycock, the sole executor. The testator, after making some bequests, leaves one-fourth of the ultimate residue of his property to his daughter Harriette Louisa, and three-fourths to his daughter Augusta Edwyna.

The following legacies have recently been left to hospitals and other medical charities:—Mr. Thomas Phillips Danson, of 54, Merton-road, Bootle, near Liverpool, £1000 to the Endowment Fund of the Bootle Borough Hospital, and £500 to the Liverpool Dispensaries.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Lambeth.—In the parish of Lambeth the birth and death rates for 1885 were 33·9 and 18·6 per 1000 respectively, the infant mortality under one year of age being at the rate of 131 per 1000 registered births. Amongst the zymotic diseases small-pox caused 85 deaths. As regards cases of this disease, it is stated that 509 came under notice, the districts in which it was most prevalent being Vauxhall and Stockwell. At Stockwell sixty-eight houses were invaded within half a mile of the Small-pox Hospital, the majority of the cases being, as in 1884, within the quarter-mile area. In 1884 Mr. Verdon brought forward some points which, in his opinion, militated against the theory of the aerial dissemination of the small-pox infection, and one of these was the fact that no cases had occurred in the forty houses situated upon the west side of Hargwyne-street, near to the hospital buildings. In 1885, however, the houses no longer enjoyed a similar immunity, and Mr. Verdon states distinctly that the districts in which the Asylums Board Hospitals are situated throughout the metropolis have in every epidemic suffered severely; there has, indeed, been an exceptional prevalence of small-pox in their vicinity. He, however, still believes that aerial dissemination is not the principal factor, and one of the points on which he relies as to this is the alleged comparative escape of children before vaccination. Thus he points out that 427 children were born within the half-mile area in the first six months of 1885, and he takes it for granted that as a rule such children would remain unvaccinated for about three months. From January 1st to July 28th, 293 cases of small-pox were admitted into the hospital, and no cases occurred amongst the children referred to except in two instances, where, it is alleged, the origin of the infection could be traced. Assuming that Dr. Verdon is correct, and that these two which he heard of were really all that did take place in a district where there is no compulsory notification, all proves is that, whatever the means by which small-pox spreads, it did not, for some reason or other, operate to a large extent on these infants. But the argument is no stronger against aerial communication than against any other method of infection—as for example, sewer infection, which he seems, on insufficient grounds we think, to regard as a principal cause of small-pox spread. The percentage of deaths amongst the vaccinated was 6·7; amongst the unvaccinated it was 78·5.

St. Luke's.—Dr. Yarrow devotes a large portion of his report to the consideration of statistics, the interest of which is mainly local. The corrected death-rate for 1885 was 22·7 per 1000. Measles and scarlet fever were more than usually prevalent. The number of cases of "fever" appearing on the Poor-law officer's books are stated to have been 7 only, and this is compared with 706 in 1865. The precise meaning of this is not clear. It can hardly mean that only 7 persons in receipt of relief had fever in 1885, and if other cases are now removed to the Asylums Board Hospitals, and are hence eliminated from the Poor-law medical officer's books, the comparison does not hold good. A large amount of sanitary work is steadily in progress, regulations have been decided on as to houses let in lodgings, and a considerable portion of land is occupied with artisans' and labourers' dwellings.

Bethnal-green.—In an extensive account of the conditions of this district, in so far as they point to the need of nuisance inspection, Dr. Bate states that in the whole of the metropolis there are 103 nuisance inspectors, this giving a rough average of one inspector to 40,000 inhabitants. The variations are, however, great. Thus, Greenwich and St. Olave's each have only one inspector, the population of the first being 148,545, and that of the latter 10,000 only. In Bethnal-green there is one inspector to every 65,000 inhabitants, and difficulties have arisen as to their relationship to the medical officer of health. The death-rate for Bethnal-green during 1885 was 22·08 per 1000, and the birth-rate 39·96. In the matter of making arrangements with the Metropolitan Asylums Board for the isolation of non-paupers, the vestry decided that no action was necessary, because the persons removed from their district to hospital either were, or by reason of their illness became, paupers. We imagine that many sanitary authorities in London take the view that, as the metropolis has an isolation authority, there is no need for other bodies to take up the work. The new Washington Lyons disinfecting apparatus is giving every satisfaction; before it did so it required to be properly covered with some non-conducting material, in order to prevent the spoiling of certain articles by means of the condensed water from the steam.

Bath Rural District.—Dr. Harper's annual reports on this district generally show a steady amount of sanitary work, and that for 1885 forms no exception. The death-rate was higher than usual—namely, 17·0 per 1000, but the increase was due to deaths amongst elderly people in the suburbs of Bath. Tiverton is evidently a portion of the district which needs substantial sanitary improvements. This last report refers to it again as having been the scene of nine fatal and thirteen non-fatal attacks of diphtheria, and it is stated that the people lived in damp stuffy dwellings, amongst a variety of insanitary conditions. We learn that sewer ventilation and refuse removal have been improved; the improvement has come none too soon, and we hope it may continue. During the summer months the authorities themselves undertook the removal of refuse in the populous parts of Tiverton and Weston, but it appears to have been of a restricted character. The removal ought to have been general, and where it is professedly undertaken by the authority, occupiers should test the matter by resort to measures indicated under Sect. 43 of the Public Health Act. But it would be still better if, in all the more populous parishes, scavenging were always carried out by the authority, and not imposed on occupiers, who have no means of properly carrying it out. When diphtheria was prevalent, considerable precautions were resorted to, and we are glad to find that the isolation hospital was useful both for this disease and other infectious fevers.

Birmingham.—During the third quarter of the present year diarrhœa was accountable for 543 deaths, or 86 per cent. of the gross number in the group of zymotic diseases, this rate being somewhat lower than that for 1884, but nearly double that for the summer of last year. During 1885, August and Septe[illegible]ool, and the contrast which [illegible]red Hill to [illegible]mind his

readers that he has frequently dealt upon the obvious connexion between summer diarrhœa and a high temperature. He also records the mean temperatures of the third quarters of 1884, 1885, and 1886 as 61·4°, 58·0°, and 60·1° respectively, and shows that the corresponding death-rates from diarrhœa per 1000 persons—namely, 5·3, 2·2, and 5·0—again bear out this view. With regard to the deaths from this cause during the past quarter, they were nearly all in children under two years of age, no less than 76 per cent. being under one year of age, and those under five years amounting to 96 per cent. of the total, leaving only a percentage of 4 to be distributed among the remainder of the population.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5551 births and 3529 deaths were registered during the week ending Nov. 27th. The annual death-rate in these towns, which had been 18·2, 19·5, and 19·1 per 1000 in the preceding three weeks, rose last week to 20·2. During the first eight weeks of the current quarter the death-rate in these towns averaged 19·1 per 1000, and was 2·3 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 13·4 in Brighton, 13·7 in Birkenhead, 15·3 in Derby, and 15·6 in Sunderland. The rates in the other towns ranged upwards to 26·2 in Bristol, 26·7 in Wolverhampton, 26·7 in Halifax, and 29·5 in Norwich. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 411 and 402 in the preceding two weeks, further declined last week to 400; they included 144 from measles, 75 from scarlet fever, 55 from "fever" (principally enteric), 54 from whooping-cough, 37 from diphtheria, 35 from diarrhœa, and not one from small-pox. No death from any of these zymotic diseases was registered last week in Brighton or in Birkenhead; whereas they caused the highest death-rates in Preston, Huddersfield, Wolverhampton, and Leeds. The greatest mortality from measles occurred in Halifax, Leeds, Huddersfield, and Wolverhampton; from scarlet fever, in Liverpool, Bradford, Sheffield, and Blackburn; from whooping-cough, in Leeds and Norwich; and from "fever," in Manchester, Norwich, Plymouth, and Bolton. The 37 deaths from diphtheria in the twenty-eight towns included 24 in London, 2 in Birmingham, 2 in Liverpool, 2 in Halifax, and 2 in Newcastle-upon-Tyne. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 293, 321, and 346 in the preceding three weeks, further rose last week to 413, but were 61 below the corrected average. The causes of 83, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Sunderland, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Blackburn, Oldham, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·1 and 21·4 per 1000 in the preceding two weeks, was again 21·4 in the week ending Nov. 27th; this rate was 1·2 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 16·3 and 16·4 in Leith and Perth, to 23·9 in Aberdeen and 25·3 in Glasgow. The 528 deaths in the eight towns last week were within one of the number in the previous week, and included 17 which were referred to whooping-cough, 17 to diarrhœa, 14 to scarlet fever, 8 to "fever" (typhus, enteric, or simple), 4 to diphtheria, 4 to measles, and not one to small-pox; in all, 64 deaths resulted from these principal zymotic diseases, showing a further decline from 81 and 77 returned in the preceding two weeks. These 64 deaths were equal to an annual rate of 2·6 per 1000, which was 0·3 above the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough had been 17 and 19 in the previous [illegible] last week to 17, of which 13 occurred in Glasgow and 2 in Aberdeen. The deaths attributed to diarrhœa, which had declined in the previous five weeks from 46 to 21, further fell last week to 19, and included 6 in Glasgow, 5 in Dundee, and 3 in Edinburgh. The deaths from scarlet fever, which had been 16, 23, and 24 in the preceding three weeks, fell last week to 14, of which 9 occurred in Glasgow, 2 in Dundee, and 2 in Aberdeen. The 8 deaths referred to "fever," of which 4 were returned in Glasgow, exceeded the number returned in the previous week by 2. The 4 fatal cases of diphtheria and measles scarcely differed from the numbers in the previous week; 3 deaths from each of these two diseases occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had increased in the preceding five weeks from 79 to 137, declined again last week to 125, and were no fewer than 46 below the number in the corresponding week of last year. The causes of 71, or nearly 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 26·2, 23·6, and 24·5 per 1000 in the preceding three weeks, rose again to 25·3 in the week ending Nov. 27th. During the first eight weeks of the current quarter the death-rate in the city averaged 23·5; the mean rate during the same period was 17·5 in London and 18·9 in Edinburgh. The 171 deaths in Dublin last week showed an increase of 5 upon the numbers in the previous two weeks, and included 7 which were referred to scarlet fever, 7 to "fever," (typhus, enteric, or simple), 4 to diarrhœa, 3 to whooping-cough, 1 to diphtheria, and not one either to small-pox or measles. Thus 22 deaths resulted from these principal zymotic diseases, against 32, 23, and 20 in the previous three weeks; they were equal to an annual rate of 3·3 per 1000, the rates from the same diseases last week being but 1·8 in London and 0·8 in Edinburgh. The fatal cases of scarlet fever, which had been 15 and 10 in the previous two weeks, further declined last week to 7. The 7 deaths referred to "fever," on the other hand, exceeded the numbers returned in recent weeks; while those from diarrhœa and whooping-cough scarcely differed from those in recent weeks. Two inquest cases and one death from violence were registered; and 57, or a third, of the deaths occurred in public institutions. The deaths both of infants and of elderly persons showed a considerable increase upon the numbers in the previous week. The causes of 18, or more than 10 per cent., of the deaths registered during the week were not certified.

SANITARY CONDITION OF JAMAICA.

The report of the Registrar-General of Jamaica upon the vital statistics and health of that island in the year 1884-85, signifying the year ending 30th September, 1885, has recently come to hand. We must once more enter a protest against the obvious depreciation in the value of the report from the fact that it does not deal with the complete year ending December, and thus afford comparison with similar statistical reports relating to others of the West Indian Islands, and to other British colonies. The estimated mean population of Jamaica in the year 1884-5 is 596,383; it is pointed out, however, that emigration to the Isthmus of Panama during the last two or three years, for the purpose of the Canal, has resulted in a net loss to the population of more than 20,000 persons, almost exclusively male adults, and equal to one-fifth of the male population at the reproductive ages. The effect of this depletion of the population upon its marriage, birth, and death rates must be considerable. The recorded marriage-rate in Jamaica is always low, and was in 1884-5 equal to 10·0 persons married per 1000 of the population, corresponding with the rate in the preceding year. The birth-rate was 37·8 per 1000, and it is worthy of note, as an exceptional fact, that the births of females exceeded those of males. Bearing in mind the large proportion of male adults temporarily absent, the birth-rate is very high. In connexion with the low marriage-rate, the high rate of illegitimacy is very noticeable. In the year under notice the proportion of illegitimate births was equal to 59·9 per cent. of the total births, and differed but slightly from the mean proportion in the preceding six years. The death-rate in the island was equal to 22·6 per 1000, and was almost identical with the rate in the preceding year. The proportion of infant mortality, bearing in

mind both the climate and the excessively large proportion of illegitimacy, must be considered low. The deaths under one year of age were equal to 159 per 1000 of the recorded births, a rate which compares favourably with that recorded in most European countries. In dealing with the statistics of the causes of death we are faced with the fact that in but 2449 of the 13,500, or only 18·1 per cent., of the deaths recorded in the year had there been any medical attendance during the last illness, and therefore only in this proportion of cases was there any professional evidence of the cause of death. Under these circumstances, the statistics of causes of death are of doubtful value, and doubt is suggested whether the recorded deaths can even approximately represent the actual number of deaths that occur in the island. It will suffice to note that 4098 of the 13,500 deaths in the year were classed to zymotic diseases, including 2139 from undistinguished forms of fever, and 295 from "fever" distinguished as enteric, simple continued, typhus, cerebro-spinal, intermittent, remittent, yellow, or malarial. The deaths referred to measles, scarlet fever, diphtheria, and whooping-cough were comparatively few, but it is quite possible that fatal cases of these diseases may, under the circumstances, have been returned under the heading "fever undistinguished." It is sufficiently noteworthy that while the death-rate from all causes in Jamaica is said not to exceed 22·6 per 1000, the rate from zymotic diseases appears to have been equal to 6·9 per 1000, or nearly a third of the entire mortality. The more than doubt that exists of the value of these statistics of causes of death in Jamaica does not encourage further reference to the rates of mortality from different diseases in the island.

Correspondence.

"Audi alteram partem."

THE MEDICAL COUNCIL AND MR. W. H. H. DAY.

To the Editor of THE LANCET.

SIR,—As an article on, and a report of, the proceedings of the General Medical Council as regards the case of myself and Mr. Davenport appeared in your issue of the 20th inst., which is calculated to leave an injurious impression on the minds of your readers as to my conduct, and to misrepresent me to the profession, I must request your insertion of the following statement, which I have tabulated for the sake of brevity:—

1. Although the practice in Westminster is mine in law, and consequently I am entitled to the profits thereof, I have never touched a farthing of them, as my connexion with that practice has been one of principle and not of profit.

2. I deprecate most strongly the singling out from the large army of "sine diploma" men throughout the country for the purpose of prosecution—without previous warning—of a man who has passed the Final Examination of the Royal College of Surgeons of England in *Surgery*.

3. I hold that this act, as well as being contrary to the spirit of fair-play supposed to animate most Englishmen, was calculated to lower the prestige of the College as an examining body before the public.

4. I hold that it is little short of a public scandal that a post-mortem examination should be made and an inquest held on the body of a person who had been seen by two qualified men and a student who had passed the College Final in Medicine and Surgery two days before his death.

5. The late Drs. Moxon and Mahomed held the same opinion as myself as to the impropriety of this prosecution: the former having spent some time at the police-court for the purpose of testifying in the defendant's favour; and the latter having written a letter, which is now in my possession, in which he deplores the fact of Mr. Davenport having been made the subject of a prosecution, says he is not the sort of person against whom the law against unqualified practice was intended to be set in motion, and [illegible]ally speaks of him as being *in fact*, if not *in law*, "*a well-trained surgeon or medical man, in the ordinary sense of the word.*"

6. I have forwarded to the Branch Council for England, to whom my case was referred, a full explanation of my conduct, in which I have pointed out to them that as the "unqualified person" in question has passed the same examination on the strength of which in 1878 I received my diploma, and they admitted me on to the Register, he can hardly be considered as "unqualified" within the meaning of their resolution of April, 1883.

7. Under that resolution the Council have no power against me, as I have not practised in Westminster "for gain."

8. I am not attempting to argue that Mr. Davenport is a legally qualified man, but I do claim that he has not been treated with the courtesy due to a full-curriculum student who has passed four-fifths of his Final, but as though he were some dispenser or herbalist who, presuming on his knowledge of drugs, had attempted to act as attendant on the sick.

9. Such being the opinion I formed on the justice of this prosecution, I have loyally endeavoured, at great trouble and expense to myself, so to identify myself with the Westminster practice that the conduct of it should not be open to the censure of anyone. This I did in defence of a friend against whom I considered a great injustice had been done in, i.e., expecting him to qualify immediately.

10. It was the account of the prosecution in the daily papers which brought me forward in defence of my friend, and under no other circumstances should I have dreamt of allowing him to act as my assistant under circumstances which might perhaps be open to misconstruction.

11. While not arguing that I have acted wisely in this affair, or attempting to defend my action in the abstract, I at the same time deny that I have done anything to justify the use of such words as "criminal," "misconduct," and "Public Prosecutor," in connexion with my name, and I am quite willing to leave the profession to form their own opinion on my conduct.

12. As regards my being represented as the proprietor of a dispensary, no one can deplore more than I do the system under which a medical man is expected to supply "advice and medicine" for about half the sum that a druggist would charge for the medicine alone.

13. I hope the publication of this will lead to the expression of some opinions on this most unique case.

I remain, Sir, your obedient servant,

WALTER H. H. DAY, M.B. Trin. Coll. Toronto,
M.R.C.S., L.R.C.P. Edin.

East Dulwich, S.E., Nov. 29th.

*** The terms to which Mr. Day takes exception were not used by us, nor did we quote or allude to them in our editorial remarks. We readily accept Mr. Day's explanations of the motives which weighed with him in permitting his name to be used in connexion with the dispensary at Westminster. They are of a kindly nature, and dissociated from motives of "gain." We cannot accept all his argument about the legal or moral position of Mr. Davenport, which, again, is not at present under consideration. It is obvious that a man must either be qualified or unqualified; the door of the profession must either be "open or shut." However near being qualified, if not legally so, he must be treated as unqualified.—ED. L.

THE APOTHECARIES' SOCIETY AND THE CONJOINT SCHEME.

To the Editor of THE LANCET.

SIR,—I am delighted with the letter of "Ye Humble Apothecarie" in your last number, and am very pleased to believe that in the far past the apothecary was of higher status than the surgeon. My question, however, is not answered by him, and I venture to repeat it: "Is not an L.S.A., who has taken no other diploma, *at the present time* in every practical sense a practitioner of an inferior grade?" I have no doubt whatever that the reply must be Yes, and that at the present time every L.S.A. who can obtain an additional qualification does so.

I would further point out that the Apothecaries' Society, by passing gentlemen on a minimum curriculum and a minimum examination, performs a very useful duty, and that should it depart from its present function, quasi-physicians and surgeons from over the Border, with innumerable letters attended to their names, will flock in greater numbers [illegible] and take the places now well [illegible]ical practitioner of the

past generation was an M.R.C.S. Eng. and L.S.A; that of the near future will be the M.R.C.S. Eng. and L.R.C.P. Lond.; but we must have an inferior grade if unqualified assistants and prescribing chemists are not to take away a large slice of our bread-and-butter. Why should not this inferior grade be able to obtain an English diploma? If the Conjoint Examining Board in England admit the Apothecaries' Society, the latter can only ask for an unequal authority and the nomination of two or three examiners in materia medica. Do the promoters of the present agitation really desire for it such an impotent position—one which for all practical purposes means its extinction?

I am, Sir, yours obediently,

Dec. 1st, 1886. L.S.A. (with other qualifications).

MEDICAL ATTENDANCE ON THE POOR.

To the Editor of THE LANCET.

SIR,—Another attempt is about to be made by the Metropolitan Medical Provident Association to attract public attention to the subject of the medical treatment of the working classes in London—a subject whose vast importance to the profession it is difficult to exaggerate. Sir Spencer Wells and I have signed a circular of invitation to a meeting for this purpose on Tuesday, Dec. 7th, at 4 P.M., at the rooms of the Society of Arts, in John-street, Adelphi, at which the attendance of all medical men interested in this question will be welcomed. Perhaps you will allow me to explain that this meeting is intended to be one for genuine consultation. Our object is not to recommend the scheme of provident dispensaries, which is now being worked by the above-mentioned Association, but to ascertain if possible if that or any other scheme will command sufficient support from the public and the profession to place the medical attendance on the poor upon a footing more satisfactory to reason and justice. The provident dispensaries have been greatly discredited by the prevalence of "bogus" dispensaries which have assumed the title of "provident," while they are really cheap doctor's shops, and are used as a means of evading the regulations of the Colleges as to advertising, and they no doubt, like other human institutions, have their own intrinsic drawbacks. We have only supported them hitherto as on the whole the best practical step known to us towards the solution of the problem. But we invite the attendance of the opponents as much as that of the friends of that scheme, provided they come prepared to co-operate with us in our real object—which is, I repeat, not to establish provident dispensaries, but to devise some means of relieving the medical profession and the poor from the evils of the present system. May I add that such a reform can only be carried out by the exertions of the medical profession themselves. We have found plenty of persons ready to criticise our proposals, but few hitherto who have given any practical suggestions, and fewer who would spend their own time and labour on the attempt. All medical men practising among the poor complain of the increasing difficulty of making a living, due chiefly to the competition of gratuitous institutions, and of the private "dispensaries" and "sick clubs." We invite them now to join us in our earnest endeavour to introduce a better state of things.

I am, Sir, your obedient servant,

Great Cumberland-place, Nov. 29th, 1886. T. HOLMES.

WORKHOUSE INFIRMARIES AND CLINICAL STUDY.

To the Editor of THE LANCET.

SIR,—With reference to your comment on the very able memorandum of Mr. Vallance, for the improvement of the medical administration of the Whitechapel Infirmary, and the advantages that would accrue from a modification of existing arrangements, I can thoroughly endorse a great deal that has fallen from the pen of that gentleman; but the question is a very vexed one, and one that requires mature consideration, on account of the peculiar and dual control in the administration of these institutions. As regards the visiting staff and the resident medical officer, you state that he (the resident medical officer) [illegible] to the said visiting staff as he is to [illegible]

be very anomalous, as how would the visiting staff be placed as regards the guardians—would they be under the control of the Board? If not, how about expenditure for drugs, stimulants, instruments, &c.? Such would be beset with difficulties when the resident medical officer presented his estimate for the consideration of the Board. Touching the visiting staff, you say, Appoint a visiting physician and surgeon. How about the special diseases—viz., eye, women, &c.: would you have specialists for them also? I cannot but think there is not sufficient material for a visiting physician, much less a visiting surgeon. A great part of the patients who seek admission to the infirmaries are people suffering from the dire effects of an ill-spent life—viz., the three D's (dirt, destitution, and drink). It is perfectly wonderful the effect of ablution, H.D., and a regulated diet; in fact, dietetics play a most important part in the treatment. Such cases, I maintain, are not cases for a visiting physician. The other medical cases, as well as surgical, are not such that the medical superintendent, along with his assistant medical officer, could not manage under existing circumstances, with credit to themselves and the profession, as well as to the patient. The cases that do require any special treatment, whether medical or surgical, can always be relieved after due consultation of the medical superintendent and his assistant that such a case requires the attention of a hospital physician or surgeon. It must be borne in mind that the medical superintendents and the assistant medical officers at the present time are men who take a great interest in their work, and keep up the work of the day. Concerning the nervous diseases, the majority of the cases are usually sent from hospitals as incurable (here again diet plays a most important part); in fact, if the institutions went under the designation of "hospitals for the incurable and infirm poor," it would be more appropriate than their present appellation of "union infirmaries." If any cases are obscure, the special physicians and surgeons are only too willing to give their aid. As to students, there is really not sufficient to induce a diligent student to come, as he can always find sufficient work in his hospital—that is, if he be a student of medicine and not a medical student; if they do not attend our special hospitals, much more would they shun our infirmaries. Touching the instruction of nurses, could not the medical superintendent, in conjunction with his assistant, give them all they require? Besides, the nursing staff are not solely confined to attendance on the sick; they have other duties to perform which do not fall to the lot of a hospital nurse viz., serve dinners, look after clothing, &c., which absorb a great portion of their time. The whole thing is replete with difficulties. The course, I think, most feasible to pursue would be to have a consulting physician and surgeon, and after the medical superintendent and the assistant medical officer have consulted concerning the case, and have come to the conclusion that it is a fit case for a consultant, let them send for him. I may add, in conclusion, that great credit is due to Mr. Vallance for the lucid and able manner in which he has brought forward his scheme; the Whitechapel Board are to be congratulated on such a clever and efficient officer.

I am, Sir, yours &c.,

City of London Infirmary, E., Nov. 1886. W. GEM.

THE FELLOWS AND MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—Will you allow me to suggest a scheme by which most of the differences between the Fellows and Members of the College of Surgeons might be set at rest. I do not recollect to have seen such a proposal before, but it may possibly have escaped me. It is that the Fellows should be entitled to two votes each on all College matters, and the Members to one. I would make all offices and honours tenable by either, and all should be subject to election. A certain number of the members of Council should be elected periodically, and there is little doubt but that Fellows would generally be chosen; or, if not, that old and respected Members, who should be equally welcome to the Board, would be selected instead. Of course the inequality of voting power would cease if a Member were elected.

With regard to the College of Physicians, it seems to me that a great error has been committed by the Council. There [illegible] Fellows and Members here also who appear to me (*pace*

Mr. Erichsen) to correspond in degree to the same classes in the other College; and as in the latter all are surgeons, so in the former all are physicians. But those who possess merely the licence to practise are surely not physicians, though they call themselves so; and if such title is assumed by the consent of the two higher classes, it is quite time the matter is authoritatively looked to. There is not a corresponding body amongst surgeons at all to this class.

With regard to the title of "Doctor" I cannot see any just or sufficient reason why its value should be depreciated by allowing its assumption by any who have not passed some examination other than that for surgeon or general practitioner, though I would be quite willing to grant it to any who subjected themselves to some examination of this sort, having first qualified by a surgical and medical examination as at present.

The claim of the Apothecaries' Society to a share in the power of examining for an entrance into the profession is as good, or better, than that of either of the Colleges. For many years it was far more dreaded than the examination of the College of Surgeons, and that of the College of Physicians is much younger. Long may it still exist and flourish.

I am, Sir, yours truly,

Nov. 1886. L.S.A., M.D., F.R.C.S.

THE CHARTER OF CHARLES I.

To the Editor of THE LANCET.

SIR, There are several legal points connected with the present position of affairs and with the existing Charters on which it is desirable that the Council, if they have not already done so, should take legal opinion, and Mr. Erichsen would render a real service to the College by urging upon the Council that the opinion of the solicitor to the College should be published on the following points:—

1. Whether the right to hold lands and houses to the value of £2000 a year is given by the Charters to the Members of the College or to the Council?

2. Whether the Council have not largely exceeded the limit of £2000 a year?

3. Whether the Council have thereby incurred any penalties under any Statute of Mortmain, and if so what; and whether such penalty falls on the Council or on the College?

4. Whether there is any authority in the Charters for the Council holding lands or houses conjointly with the College of Physicians?

I trust Mr. Erichsen will not dissent from the view that this is a reasonable request.

I am, Sir, yours faithfully,

November, 1886. H. NELSON HARDY.

THE M.CH. DEGREE.

To the Editor of THE LANCET.

SIR,—When the attention of the medical profession is being directed towards reform and removing anomalies, it seems a fitting occasion to direct attention to a distinct grievance which a large number of the profession suffer from, and to agitate for its removal. It is a palpable injustice to the holders of the degree of Master in Surgery that, in the case of a large number of hospitals and infirmaries, that degree does not qualify them to apply for the post of hon. surgeon.

A representation from the Medical Council to the governing boards of the hospitals in question would no doubt have the effect of inducing them to alter a superannuated rule not consonant with the times, and which is a plain injustice to a large number of well-educated and competent surgeons. In the majority of cases these rules were framed at a time when the degree in question was either non-existent or but little known. Such is not now the case, and it is time that the rules were changed to meet the altered circumstances. A representation such as I have suggested would doubtless be successful where the personal efforts of the comparatively small number of the holders of the degree would be inadequate.

I am, Sir, your obedient servant,

Nov. 1886. M.CH

LONDON SEWAGE.

To the Editor of THE LANCET.

SIR,—Advertisements are now being circulated seeking tenders for the construction of *additional* tank room at Barking, in order that Mr. Dibden may have greater space for his chemical experiments, which practical men regard as worthless in relation to the ultimate solution of the great sewage question.

The cost of the additional works required at the present outfalls, according to the joint report of the engineer and chemist of the Metropolitan Board, was £1,140,000, involving a charge on the ratepayers of £34,000 a year. Yet such is the rapid growth of population in the metropolis, particularly in the east, that it is stated on good authority that 65,000 persons are now being added yearly to a population already numbering five millions, so that it is quite certain that both Barking and Crossness will in a few years be densely surrounded with population and dwellings. Let me point out that this expenditure of £1,140,000, great as it is, cannot prevent the condemnation of the present outfalls in a very few years. It appears, therefore, to be a monstrous waste of good money sanctioned by certain members of the Board, who resolutely refuse to consider anything else, although Messrs. Jones and Denton's Canvey Island scheme has much to recommend it, and although they offer to place all their plans and details before a competent independent engineer, when they say they can prove that their proposal, if adopted, would save the metropolis one-half the outlay resulting from chemical treatment.—Yours faithfully,

Nov. 1886. OBSERVER.

"THE LIABILITY OF FRIENDLY SOCIETIES FOR EXTRA MEDICAL ASSISTANCE."

To the Editor of THE LANCET.

SIR,—I find on page 1044 of THE LANCET for Nov. 27th, 1886, a paragraph under the above heading, and as the information contained in the paragraph is *untrue* and calculated to damage the reputation of the Nottingham Friendly Societies' Medical Institution, I hope you will contradict the report in your next issue. 1. The action in the County Court was *not* taken by Dr. Collins against the Friendly Societies' Medical Institution, but against the patient himself. 2. Dr. Collins was *not* an officer of the Nottingham Friendly Societies' Medical Institution. 3. The Nottingham Friendly Societies' Medical Institution had two *doubly qualified* medical officers engaged on the staff at that time, the second gentleman (Dr. Rodgers) being fully competent to perform the operation. 4. Whenever the Nottingham Friendly Societies' Medical Institution has engaged the services of medical men the Committee has paid them punctually and liberally.—I am Sir, yours respectfully,

Nottingham, Nov. 28th, 1886. J. LEE, Secretary.

LIVERPOOL.

(From our own Correspondent.)

THE MAYOR AND THE ROYAL SOUTHERN HOSPITAL.

FOLLOWING the annual custom of more than forty years, the newly elected mayor, Mr. James Poole, attended the morning service at St. Barnabas' Church on the 21st inst. (the second Sunday after his election), when a sermon was preached by Archdeacon Gore, and a collection was made on behalf of the funds of the hospital. The collection realised £101. After the service the Mayor visited the hospital, which is within a short distance of St. Barnabas, accompanied by some of the medical staff, and the aldermen and city councillors, who had attended service.

HOSPITAL FOR INFECTIOUS DISEASES.

A correspondence has taken place between the Town Clerk and the Local Government Board in regard to the erection of a hospital for infectious diseases in Grafton-street. Subject [illegible]ration in the plans as to the [illegible]t the proposed hospital,

the Local Government Board has given its sanction to the borrowing of £15,000 by the Corporation for the erection of the hospital on the Grafton-street site.

CORONERS' INQUESTS IN LIVERPOOL DURING THE YEAR 1885-86.

The annual report of the Head Constable of Liverpool gives, amongst other interesting details, a table of the inquests held before the city coroner from Sept. 30th, 1885, to Sept. 29th, 1886. The total number was 615, in addition to which there were 695 other cases of death reported to the coroner by the police and others, thus making a total of 1310 deaths investigated by the coroner during the year. As might have been expected, the greater proportion of inquests were held on the bodies of males, the number of these being 376, and that of females 239. Among the causes of death indicated in the verdicts there were 60 deaths due to "natural causes," 5 from "want, cold, and exposure," 5 from "disease aggravated by neglect," 49 from "excessive drinking," 57 "found dead," 46 from "injuries, cause unknown," 41 from "other causes," 33 from "suicide," 4 from "manslaughter," and 5 from "murder."

A YEAR'S ACCIDENTS IN LIVERPOOL.

Another table gives the number of accidents in Liverpool during the same period, which reached a total of 2137. Of these, 411 persons were run over by carts, cars, &c., the accidents being fatal in 17 cases. There were 383 cases of falling into docks, canals, &c., of which 22 only were fatal, showing the promptitude with which lives are saved by the police and bystanders. There were 29 cases of burning, of which 3 were fatal. Firearms caused 5 accidents, of which 1 was fatal. There were, as might have been expected, many accidents resulting in injuries in dock works, on dock quays, and on board vessels in docks, the numbers being respectively 5, 122, and 224; of these only 7 ended fatally.

PROPOSED NEW MORTUARY.

Allusion has been made in previous letters to the dead-house situated at the Prince's Dock, near to the principal landing-places of the River Mersey, and in a position, central and otherwise, convenient for its purpose. But the structure is in every respect unfit even for the bare purpose of affording shelter for the dead bodies deposited in it, and still more so for the necropsies, which frequently have to be held in it under conditions involving the greatest discomfort to the medical examiners. It is satisfactory therefore to say that there is now some prospect of a new mortuary being erected, with every reasonable modern improvement.

Liverpool, Nov. 30th.

MANCHESTER.

(From our own Correspondent.)

THE HOSPITALS.

IT was recently stated in these columns that the Royal Infirmary had not lately received any very large benefaction. Since then it has, however, received under the will of a late alderman no less a sum than £10,000. In acknowledging the munificence of this bequest, the chairman of the Board, on Monday last expressed a hope that the public would not imagine that the infirmary was thus in any way less needful of support, and stated that the banking account was overdrawn to the extent of more than £25,000. Amongst the other hospitals that have benefited under Mr. Rose's will are the Salford Royal and St. Mary's. To the latter is bequeathed £2000, which will be very acceptable in view of the present efforts to raise money for the reconstruction or rebuilding of the hospital. The bazaar lately organised on behalf of this fund by the ladies employed on the staff of the Manchester Post-office realised nearly £400. This bazaar is believed to be the first in the kingdom got up and managed entirely by the *employées* of the postal service. The Salford Hospital received £5000 under the same will, and, seeing that £11,000 has already been paid on account of the extensions now going on, will prove very acceptable. At the annual meeting held on Nov. 17th it was stated that the annual expenditure had been £4120, against an income of £4429, leaving a balance of £300, a rather unusual thing in these days of hospital financial difficulties. It is hoped that the [illegible] will be ready for use early in the [illegible]

SCARLET FEVER.

The epidemic of scarlet fever shows at present but little sign of abatement, and it is fortunate that no other infectious disease is prevalent at the same time, as the hospital accommodation available for these diseases is now almost fully utilised. At a late meeting of the Manchester Board of Guardians, the Local Government Board inspector alluded to the occurrence of some cases of that disease amongst the children in the Swinton Schools belonging to the guardians, and criticised adversely the present arrangement for isolation, &c., of patients suffering from any infectious disease there.

LECTURES.

The Manchester and Salford Sanitary Association commenced their annual series of lectures last week, when the first of the series was delivered by Dr. Ransome, on some "Preventable Causes of Disease." The meeting was presided over by Mr. Councillor Pingstone, and it is an encouraging sign of the times to note how much more interest has of late been taken by many of our city councillors in the spread of sanitary knowledge amongst the masses of the people. The Combe lectures on Digestion, delivered by Professor Stirling at Owens College during the present session, have been very successful, and attended by large audiences. A hope has been expressed that in the future some arrangements may be made by which these shall be open to others beside students of the College.

THE MEDICAL SOCIETY.

A meeting of considerable interest has just been held at the College, several uncommon surgical cases being brought forward. A case of cholecystotomy was shown by Mr. Jones, and a patient on whom supra-pubic lithotomy had been performed was introduced by Dr. Cullingworth. Other cases were an ununited fracture of the clavicle in which the fragments had been wired, and a patient (shown by Mr. Southam) in whom the upper end of the humerus had been removed for a malignant growth. A paper on Summer Diarrhœa, with special reference to its possible bacterial origin, was read by Dr. H. Tomkins, who during the past summer had been studying this disease in Leicester, than which no town in England affords more ample opportunity for the work. This paper showed that in those parts of the town specially affected the air was far more abundantly loaded with germs than in other districts. Cultivations of microbes had also been made from various organs of the bodies of patients dead from diarrhœa.

The authorities have lately been successful in the Queen's Bench in reducing the rateable value of the Owen's College buildings from £3285 to £1083.

Manchester, Dec. 1st.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

BONE-SETTING.

AN inquest was held last week on the body of a sailor from North Shields, aged fifty-eight years. It appeared from the evidence that the deceased, on Oct. 23rd, had, in throwing a rope, fell and dislocated his arm at the shoulder-joint. In the words of a witness, he had been since then "bothering on with a bone-setter," who at last told him he could do no more for him, leaving the arm still unreduced. On the 17th of this month he was taken to the Newcastle Infirmary, where efforts were made at reduction under chloroform. Dr. Arnison, the senior surgeon, deposed that on the conclusion of one of these attempts the armpit was seen to swell up and fill with blood, showing that some vessel had given way. He failed to find the bleeding vessel, but believed it to be deep behind the misplaced bone. The hæmorrhage was stopped by other measures. At night it broke out again, and he was sent for by the house-surgeon, when the wound was opened and a vessel secured. Dr. Arnison remained with the man until 1.30 A.M., when all bleeding had ceased. The next evening, however, it recommenced, but he was then too weak to have anything further done, and died from exhaustion consequent upon repeated bleeding. Dr. Arnison, in his evidence, further said that probably the bloodvessel had formed adhesions to the bone and was torn in using the necessary force to get the bone reduced. "He had never

in his experience met with a similar case, but he knew such had happened in the practice of several eminent surgeons.

SHERBURN HOSPITAL.

In a previous letter I gave you some particulars as to the working of this ancient and useful charity. Since then an inspector from the Charity Commissioners has held an inquiry at the hospital with a view to the permanent increase in the amount for its maintenance. It was stated that the expenditure had increased of late, and the governors of the institution asked that the income might be permanently augmented by £650, thus bringing the amount of the income to £5500. It is hoped that the inspector may report favourably to the Commissioners.

ALCOHOLIC POISONING OF INFANTS.

It is well known, and has been frequently pointed out, that the working-classes of Sunderland feed their children most improperly. In "bad times" they get nothing, or next to nothing, and suffer from hunger; when "good times" come round they get everything, including alcoholic drinks. An inquest was held last week on a child, aged three months, which had slept with its mother, but was found dead beside her in the bed. It was shown by the evidence that the infant was "fed" on condensed milk and breast milk, but that on the advice of "a neighbour" it was also given a teaspoonful of gin "occasionally." The dangerous nature of giving alcohol to tender infants was forcibly pointed out by the coroner in this case, as it has been often done before in similar cases in Sunderland.

WHOOPING-COUGH.

At a late meeting of the Hexham Local Board the medical officer, Dr. Jackson, pointed out the influence of whooping-cough in swelling the mortality-rate in Hexham, where it had been prevalent for some months, although the public thought little of it; and the sufferers did not receive that attention which the seriousness of the disease merited, and as a consequence the deaths from it were more numerous than from other infectious diseases which were in themselves more serious. No doubt many infants perish from whooping-cough and its complications whose lives might be saved by timely medical treatment.

INFECTIOUS DISEASES IN NEWCASTLE.

The returns from practitioners to the medical officer of health prove that the scarlet fever epidemic in Newcastle shows no sign of abating. During the last fortnight a total of 109 cases of infectious disease were reported, of which 92 were from scarlet fever, and 15 from typhoid or enteric fever.

Newcastle-on-Tyne, Nov. 30th.

EDINBURGH.

(From our own Correspondent.)

UNIVERSITY UNION FANCY FAIR.

ON Tuesday the Marquis of Lorne inaugurated the monster bazaar and fancy fair, which is now being held in Edinburgh to raise funds for a University Union, which it is proposed to found on a basis similar to that of the Unions of Oxford and Cambridge. The efforts that have been made during several months with a view to securing success in this enterprise have been unremitting, and have engaged the energies of a very wide circle of the community interested in the University and its undergraduates. As far as the appearance of the bazaar is concerned, they have been crowned with great success; for the largest covered space in Edinburgh, the Waverley market, capable of holding nearly 20,000 people, has been converted into a gorgeous palace for the occasion, stocked with valuable wares from all parts of the world, including large consignments of native products from the Cape, Australia, India, and America. A series of large stalls, each with a distinctive name, and a special fancy uniform for the attendants, are ranged around the transfigured market-place; their arrangement and the sale of the goods being undertaken by a number of Edinburgh ladies, who represent the chief influences of our academic and city life. At the stalls and in the spaces between them are stationed a representative array of the youth and beauty of Edinburgh; the young ladies in fancy costumes varying according to the special stall at which they preside, and the students in the gallery costume of Queen Mary's reign. The spectacle presented by the varied array of stalls, arbours, kiosks, shows of all kinds, shooting galleries, all the paraphernalia of a country fair, which occupies one part of the market, of a theatre, a lecture room, and the bright decorations and gay costumes, is quite unique, and will certainly not be forgotten for many a day; and the good results of all the efforts which have been made, should the Union prove as successful as it bids fair to do, will be of lasting benefit to the University in providing it with what has as yet been missing in Edinburgh—a common bond in our undergraduate social system.

THE ROYAL INFIRMARY.

The managers of the Royal Infirmary have elected Mr. James W. B. Hodsdon, F.R.C.S.Ed., to the vacant post of assistant-surgeon. In securing his services upon the staff of the institution, they have made an acceptable and a useful appointment. His training in surgery has been very varied and unusually comprehensive; he is known as a good teacher, and is popular alike amongst students and patients; and as he has also the reputation of being an able experimentalist and an original thinker, his appointment will add considerably to the teaching power of the Edinburgh School, and tend in due time to enhance its reputation.

Edinburgh, Nov. 30th.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

IN reference to the recent regulations for the medical curriculum of this University, published in last week's LANCET, I may add that the date at which this rearrangement of the medical course shall be brought into operation has been ordered by the Senate as follows:—(*a*) All medical students who shall not have passed the first examination in medicine prior to Nov. 1st, 1887, shall come under the operation of the whole of this new regulation. (*b*) Medical students who shall have passed the first examination in medicine prior to Nov. 1st, 1887, shall be required to pass subsequently the second examination in medicine as at present, in the four subjects of anatomy, physiology, chemistry, and pharmacology. (*c*) Should any candidates qualified to present themselves for the M.B. examination desire to be allowed the privilege of availing themselves of the division of subjects of examination mentioned in No. 7, they will be allowed to do so even during the coming year. (*d*) All medical students who on Sept. 29th, 1887, shall not be of more than two years' standing as medical students shall come under the operation of the new regulations as to the third and fourth years of medical studies. (*e*) Where prior to the promulgation of this scheme courses of lectures or hospitals have been attended in an order consistent with the existing regulations, but not in the order prescribed in this scheme, certificates of such attendance will be accepted. But after the promulgation of this scheme all attendances at courses of lectures and hospitals must take place conformably with the regulations herein set out.

THE ENTRIES AT THE DUBLIN MEDICAL SCHOOLS.

The following is the return of anatomical students for t present session:—

School.	Session 1886-7.	Session 1885-6.
Trinity College	225	220
Ledwich	217	212
Carmichael	181	179
Royal College of Surgeons ...	129	130
Catholic University	80	101

From these figures it will be seen that compared with last session there is an increase of five at Trinity College and at the Ledwich respectively, and of two at the Carmichael. On the other hand, there is a decrease of twenty-one at the Catholic University, and of one at the College of Surgeons.

ACADEMY OF MEDICINE IN IRELAND.

The inaugural address at the opening meeting of the Obstetrical Section of the Academy last week was given by the President of the Section, Dr. A. V. Macan, who selected for his subject, "Bimanual Examination in the Diagnosis of Female Affections." A vote of condolence with the family of the late [illegible], a member of the Academy, was proposed by Dr. Kirkpatrick, and [illegible]

MERCER'S HOSPITAL, DUBLIN.

A meeting of the governors of this institution was held last week to investigate certain charges made against the working of the hospital by Mr. Newcomen, late deputy resident pupil, and who had been refused admission to the hospital. While Mr. Newcomen was on duty one night a patient named Farrell was admitted, and a dispute arose between the acting resident pupil and the matron and house-surgeon, in reference to the alleged ill-treatment the patient received, and who died shortly afterwards. Charges were brought by Mr. Newcomen against those officials, and the committee met on Oct. 18th last, and came to the conclusion that the charges brought by Mr. Newcomen and the widow of the deceased were not proved, and that the former should be prevented from entering the hospital again. Mr. Newcomen applied to have the matter reinvestigated by the board, and in consequence of a summons to appear, he attended at the hospital on a day last week with counsel to assist him. The governors, however, refused to admit his counsel, and the proceedings were conducted in private, when the board passed a resolution that Mr. Newcomen's letters be marked read, and that no further notice be taken of them.

DEATH OF STAFF SURGEON O'SULLIVAN, OF H.M.S. "BELLEISLE."

This gentleman, who was attached to the *Belleisle* at Kingstown Harbour, died very suddenly on Sunday night while leaving a house in Dublin, where he had been dining. He complained when about to take his departure of feeling unwell, and immediately fell on the floor. The nearest surgeon was sent for, and on his arrival pronounced Surgeon O'Sullivan to be dead. Deceased, who was a graduate in medicine of the Queen's University in Ireland, was about forty years of age, and is supposed to have succumbed from thoracic aneurysm.

ZYMOTIC DISEASES IN DUBLIN.

The two zymotic diseases which for some time past have prevailed in Dublin are scarlatina and typhoid fever. Of the latter about forty deaths have been recorded during the last three months, and almost the same number have succumbed from scarlatina during the past four weeks.

HEALTH OF CORK.

During October the death-rate was much lower than for the corresponding month of last year, or any previous year on record. Typhoid fever is still increasing, but the type of the disease seems to be of a mild character. The medical officer of health in his recent report refers to the necessity of having the principal main sewers in the city ventilated.

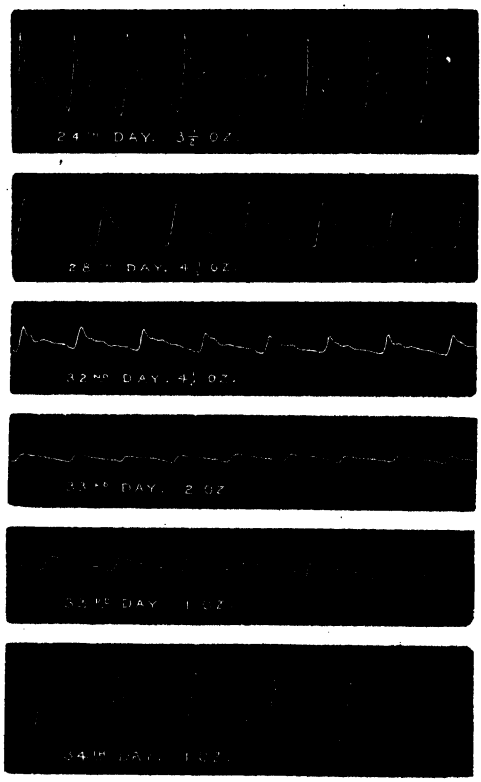
Dublin, Nov. 30th.

PARIS.

(From our own Correspondent.)

THE ADULTERATION OF WINE.

AFTER a long and laborious discussion extending over several sittings, the Academy of Medicine has delivered itself of an opinion on the question of the adulteration of wine by the addition of alcohol. The original conclusions of the committee have undergone some modifications, and now stand as follows:—The Academy, advising from a hygienic point of view, declares:—1. That the *vinage* or alcoholisation of wine by pure alcohol to the extent of two degrees may be permitted, but beyond this it should be absolutely forbidden. 2. The addition of alcohol is not only dangerous by its quantity and by the bad quality which is often used, but also because it leads to the practice of "watering," which is at the same time a fraud and an adulteration. 3. The so-called "higher" alcohols considerably increase the dangers of brandies and liqueurs, and it is reasonable to require that the spirits used for the fabrication of these products should be absolutely pure. 4. The Academy calls the attention of the authorities to the necessity of restricting the number of retail drink-shops, and of putting into force the laws for the repression of drunkenness. It would appear that the addition of two degrees of alcohol is necessary for the preservation of certain wines of low strength, and as it is very doubtful whether [illegible] admixture can be detected, the Academy may [illegible] of this authorisation.



prohibited the addition of alcohol to all wines over ten degrees, and a motion of M. Gauthier to this effect was voted, but a few minutes later, at the suggestion of M. Brouardel, the vote was negatived.

THE DISEMBARKATION OF TROOPS FROM THE EAST.

Another question of State hygiene is now occupying public attention, but in this case the Government has acted without consulting its sanitary adviser, and hence a storm of timely expostulation. Hitherto the troops returning from the East have been disembarked at Port Gros, which is at a safe distance both from Marseilles and Toulon. This station having been suppressed from financial considerations, recent arrivals have been permitted to land without any quarantine observation; but in consequence of the remonstrances of the representatives of the interested ports, who feared a fresh invasion of cholera, the Government has decided that passengers from suspected countries shall be subjected to observation at the lazaret of Frioul, a couple of miles from Marseilles. After the disembarkation of the passengers the ships are to proceed with their crews to Toulon. The town of Marseilles has suffered much of late years in its commercial prosperity, and it is feared that the near neighbourhood of an inefficient quarantine station may cause it to be considered as an infected port abroad, and so injure its maritime trade. The vicinity of the lazaret is also thought to be a real permanent danger to the town, and the Chamber of Commerce is making strong representations on the subject to the Government, and it is hoped that the measure will be reconsidered.

MERLATTI'S PAST.

Whatever may be the pathological signification of the first four tracings of Merlatti's pulse (on the twenty-fourth, twenty-eighth, thirty-second, and thirty-third days), there can be no doubt that they indicate a progressive

decrease in the volume of the blood. The fifth tracing, taken on the afternoon of the thirty-third day, caused me some surprise, as it shows a temporary restoration of the [illegible] as regards volume; but its explanation is simple. In

reply to my observation that such a tracing was not possible unless a large quantity of fluid had been quite recently absorbed, Dr. Maréchal informed me that Merlatti had been visited during the day by some of the leading members of the profession, and that, with a view to ascertain the condition of the stomach, he had been made to swallow three litres of water, and a further quantity had been taken during the afternoon. The conclusion of the medical visitors and of the committee was that the heart was normal, that the muscular system was still satisfactory, and that there was no urgency about putting an end to the fast. It may be stated that the enumeration of the blood-corpuscles showed four and a half million cells to the cubic millimetre, an increase of half a million over the first enumeration; but it must be remembered that the quality of blood has immensely decreased, and although the cells still bear the same proportion to the fluid, the total number has greatly decreased, and it is probable that if an enumeration had been again made, it would have given a very different result. My own opinion differs from that of the committee. Merlatti's pulse has varied in rapidity a good deal; certainly between 56 and 76; there is a reduplication of the second sound, and the pulse tracing indicates a similar dynamic condition of the circulation to that found in aortic insufficiency. But what appears still more significant is the odour of the breath (which is stated to be like that of a carnivorous animal), and which reminds me strongly of the odour in some cases of mental disturbance. Merlatti's determination is to achieve his fifty days' fast *quand même*. Indeed, he states that any opposition of the committee will only strengthen his resolution, and he has even hinted that it will lead him to prolong his abstinence until the 1st of January.

Paris, Dec. 1st.

THE SERVICES.

WAR OFFICE.—The Queen has been graciously pleased to approve of the following promotions being conferred upon the undermentioned officers in recognition of their services during the operations in the Soudan, 1885-86:—Surgeon-Major Henry William Alexander Mackinnon, of the Army Medical Staff, and Surgeon-Major Charles Sibthorpe, of the Indian Medical Department, to be Brigade Surgeons.

INDIA OFFICE.—The Queen has approved of the following promotion made by the Government in India:—Brigade Surgeon George Farrell, C.B., of the Bengal Medical Establishment, to be Deputy Surgeon-General.

ADMIRALTY. — The following appointment has been made: Surgeon Henry F. Jackson, to the Royal Marine Depôt at Walmer (temporarily).

ARTILLERY VOLUNTEERS.—1st Kent: Acting Surgeon J. I. Boswell resigns his appointment.—3rd Lancashire: Surgeon A. A. Corte is granted the honorary rank of Surgeon-Major.—2nd Middlesex: Surgeon and Honorary Surgeon-Major R. T. Daniell resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement.

RIFLE VOLUNTEERS.—6th Lanarkshire: Acting Surgeon J. E. Fairlie resigns his appointment.—2nd Oxfordshire: Acting Surgeon E. Cotterell resigns his appointment.

THE VOLUNTEER MEDICAL STAFF CORPS (The London Division).—Valentine Matthews, Gent., to be Surgeon.

HOSPITAL SATURDAY FUND.—At a meeting of the Board of Delegates of this fund held on the 27th ult., it was reported that the amount now in hand, after payment of all expenses, reached £9500, and that a considerable sum was yet outstanding. The aggregate to hand from the workshops is at least £500 in excess of last year, and the expenses show a decrease of £250. It was resolved that a sum of £9750 be distributed, and that the fund be closed for the present year. Lord Brassey was elected president of the fund in the place of the late Mr. Samuel Morley. A proposal for registering the fund under the Friendly Societies Act was deferred for consideration.

THE twelfth annual general meeting of subscribers to the Glasgow Western Infirmary was held on the 25th ult., when a satisfactory report was submitted by the secretary and adopted by those present.

Obituary.

MORTIMER BALDING, B.A., M.D. CANTAB., M.R.C.S.,

OF ST. ALBANS, HERTS.

MORTIMER BALDING was the youngest son of the late Mr. James Balding, of Barkway, Herts, who, himself a medical practitioner, lived to see three of his children engaged in the active pursuit of the same profession. One only of these, the eldest, now survives—Mr. D. B. Balding of Royston, who was recently nominated as a fitting representative of the general body of the profession upon the Medical Council. Mortimer was born in 1850, and received his early education at the hands of the Rev. A. E. Fowler, of Saffron Walden. In October, 1867, he entered Gonville and Caius College, Cambridge, and graduated B.A. in honours (Nat. Sci. Tripos) in 1870. He attended Addenbrooke's Hospital, and after taking his first degree in medicine proceeded to London to complete the medical curriculum at the Middlesex Hospital, where two brothers had been educated many years before. He passed through his studentship with much credit, gaining the esteem of his teachers, and always evincing the energy and honesty that characterised him throughout life. In 1873 he held the office of house-physician, throwing himself with ardour into clinical pursuits. Throughout the ten years that elapsed between his leaving London and finally settling down in country practice, he was engaged in professional work with but little intermission, either in holding travelling appointments or in taking charge of the practices of medical friends who were fortunate in securing the services of one whom they could so implicitly trust. His last travelling appointment was as medical attendant to the late Earl Grosvenor, when that nobleman visited the Marquis of Lorne, then Governor-General of Canada. Dr. Balding's services were called into requisition during this visit on the occasion of the sleigh accident to H.R.H. Princess Louise. On returning home he devoted several months to the preparation of his M.D. thesis, which was read in November, 1880. The subject he selected was "Hydatid Disease of the Liver: its Diagnosis and Treatment." It was based upon his own experience, as well as upon a careful study of recorded cases.

In January, 1883, he succeeded to the practice of the late Dr. Prior of St. Albans, and in a very short time fulfilled the most sanguine expectations of his friends as to his success. Doubtless his long training and experience in general practice stood him in good stead, and no prospect could be brighter than his at the beginning of the present year. He had married in September, 1885, and might well have anticipated a life of continued and increasing usefulness and prosperity. His career, which had opened so brightly, was, however, destined to be abruptly closed. In the spring he began to suffer from symptoms which must be undoubtedly ascribed to the malady that terminated his life; although it was not until the middle of August, after he had vainly sought to recruit his failing health by a holiday, that the existence of malignant disease of the rectum was ascertained. The fortitude with which he bore the information whereby his worst fears were realised was the wonder and admiration of his friends; and, indeed, throughout the remainder of his days he acted as few men have either the character or the courage to act in presence of a death-warrant. So long as he was able, he continued to visit his patients, and for several weeks had the advantage of the assistance of his old friend, Mr. Hughes, formerly of Bromley, Kent, whose presence and kind help were great comforts to him. Immediately on learning the nature of his illness he took steps to dispose of his practice, which eventually resulted in a partnership with Mr. A. H. Boys, who succeeds him. In October colotomy had to be performed, but the local disease continued to make rapid progress, and he sank from exhaustion on November 23rd.

Thus, at the early age of thirty-six, died a member of our profession [illegible] large knew little, but whose [illegible]acter endeared him to

many, who saw in these qualities—hidden somewhat by an unconventional manner and plainness of speech—the making of a thoroughly upright and trustworthy man. For Mortimer Balding possessed original characteristics which mark out the individual from the ordinary conventional type; and his own rectitude of conduct led him to be earnest and outspoken in condemnation of all shams and quackery. His position and success were the outcome of his character, coupled with valuable gifts of method and foresight in the conduct of affairs. The large gathering at the graveside on the 26th ult. bore silent yet eloquent testimony to the hold he had gained on the hearts of the people by his steady devotion to duty and generous dealing in the few years he had practised his profession among them.

S. C.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on Nov. 27th:

Abbott, William Louis, L.R.C.P. Lond., Philadelphia.
Darlow, Alfred, L.S.A., Redcliffe House, Plasket, Essex.
Gibbard, Thomas Wykes, L.S.A., Wellingborough.
Lewis, David Thomas, L.S.A., Stoke Newington-road.
O'Reilly, George Hartley, L.S.A., Wyndham House, Reading.
Pedley, George Aston, L.S.A., The Terrace, Camberwell.
Quarty-Papafio, Benj. W., M.B. Edin., Gold Coast, W. Africa.
Redman, William Edward, L.S.A., Steep-hill, Lincoln.
Thorpe, Frank, L.K.Q.C.P.I., Queen's-road, Oldham.
Young, Richard Weekes, L.S.A., Sydney, New South Wales.

CAMBRIDGE UNIVERSITY.—At a congregation held on the 25th ult., the degree of M.B. was conferred on the following gentlemen:—

Evan Evans, King's. | Chas. Silvested Evans, Clare.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners, held last week, the under-named was admitted a Fellow of the College:—

Thomas Falkiner Falkiner.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Nov. 25th:—

Browne Henry, M.R.C.S., Cromwell-road, Westbourne-park.
Davey, Thomas George, Helston, Cornwall.
Goodall, Henry, M.R.C.S., Abingdon Villas, Kensington.
Joaffreson, John Leslie, Park-crescent, Stoke Newington.
Johnson, John George, Lansdown-road, Clapham.
Lansdale, William, M.R.C.S., Chelsham-road, Clapham.
Marshall, Arthur Lumsden, Bournemouth.
Moxon, Alfred, Easenhall, Rugby.
Phillips, G. Gordon Owen, Castletown-road, West Kensington.
Routh, William, Irvine House, Balham-park-road, Balham.
Ward, John Alfred, Ilwarardine Castle Montford, Shropshire.
Yeoman, Wm. Metcalfe, M.R.C.S., Osmotherley, Northallerton.

THE annual Hospital Sunday collection at Hereford was held on the 28th ult.

THE Goole Cottage Hospital Saturday collection was made on the 27th ult.

THE annual dinner of the Birmingham medical students was held on the 25th ult.

A BAZAAR in aid of the fund for the building of the Mater Misericordiæ Hospital is announced to be held in Dublin on the 15th inst.

THE new infirmary at Workington, which has been built at a cost of about £3000, was formally opened on the 29th ult.

THIRTY-TWO designs have been sent in for the new workhouse hospital which the Belper Board of Guardians contemplate erecting.

A SPECIAL general meeting of the members of the Liverpool Medical Institution will be held to-night (Friday) to receive the report of the Inquiry Committee.

ON the 27th ult. Mr. B. Thompson Lowne, F.R.C.S., delivered a lecture on "Volcanoes and Earthquakes" at the Working Men's College in Great Ormond-street.

THE death on the 23rd ult. of Mr. J. W. Inger is announced. The deceased, who was in the twenty-ninth year of his age, had practised in Nottingham for six years.

AT a special meeting of the Barnsley Union Rural Sanitary Authority on the 30th ult., the medical officer reports the prevalence to a considerable amount of typhoid fever in Royston.

SUICIDE OF A RUSSIAN SURGEON.—M. Kolomnin, Professor at the St. Petersburg Surgical Academy, is reported to have committed suicide after having failed in the performance of a dangerous operation.

ON the 26th ult. a farmer was fined £10 for sending from Linton, in Cambridgeshire, to the London Central Meat Market the carcases of two sheep which were diseased and unfit for food.

ST. BARTHOLOMEW'S HOSPITAL COLLEGE.—The Preliminary Scientific Exhibition of £50 for one year, open to students of less than six months' standing, has been awarded to Messrs. Sargant and Langford (bracketed equal).

AT a special meeting of the Ripon Millenary Executive Committee on the 29th ult. it was recommended that the question of establishing a cottage hospital in that city be taken into consideration, in connexion with the Queen's jubilee, at a general meeting of the inhabitants to be called by the mayor as early as possible next year.

QUEEN'S COLLEGE, BIRMINGHAM.—An Ingleby Scholarship, after examination in obstetric medicine and surgery, and the diseases of women and children, open to students who have completed two years, has been awarded to Mr. A. H. Nott. There were no competitors for the Sydenham or Queen's Scholarships.

MEDICAL WOMEN FOR INDIA.—Miss E. Littlewood, L.R.C.P. & S. Edin., has started for Bombay. She has received the appointment of resident medical officer to the Cama Hospital for Women, opened by Lord and Lady Reay on July 31st, of which Dr. Edith Pechey and Dr. Charlotte Ellaby are the physicians.

THE TRAINED NURSES' ANNUITY FUND.—By the kind permission of the Countess of Carnwath a meeting of the committee of the Trained Nurses' Annuity Fund was held at her house in Cromwell-place on the 23rd ult., when Mrs. Bell was elected from fourteen candidates to the Albany Annuity, specially founded in memory of the late Duke of Albany, who was president of the Society.

AT a public meeting held at Bournemouth on the 29th ult., it was decided to commemorate the Queen's jubilee by the erection of a general public hospital, to be called the Victoria Hospital. An influential committee was appointed to collect subscriptions and arrange the details.

ST. MARY'S HOSPITAL.—On the 27th ult. a special dramatic performance was given at the Novelty Theatre in aid of the Maternity Fund of this institution. The piece selected was "New Men and Old Acres." As the theatre was well filled, it is satisfactory to know that the hospital in whose favour the undertaking was so successfully carried out will be a considerable gainer.

IN the calendar issued by the Council of the Yorkshire College for the current academical year, it is hinted that there is every probability of the formation in Leeds of a bearer company of the Volunteer Medical Staff Corps. The idea has now assumed a definite form, and there is no doubt that in a short time such a company will have been fairly established.

SALE OF MICROSCOPICAL PREPARATIONS.—The sale of Dr. Matthews' fine microscopical preparations, first-rate microscopes and objectives, &c., is announced for Friday, Dec. 10th, at 12.30, at 31, King-street, Covent-garden, W.C. Dr. Matthews was an ex-president of the Quekett Club.

PRESENTATION.—An illuminated address, a clock, and ornaments were on the 23rd ult. presented to Mr. Holt, the late medical superintendent of the Whitechapel Infirmary by the officials engaged at that institution.

FIRST AID.—The women's class in connexion with the St. John Ambulance Association, conducted by D'Arcy B. Carter, Esq., M.R.C.S. Eng., was examined in the "First Aid" course on the 8th ult. by Edward Atkinson, Esq., M.R.C.S. Eng., F.L.S., of Leeds, when twenty-five candidates presented themselves for examination, the whole of whom were successful.

LECTURES ON AIR POLLUTION.—The Manchester and Salford Noxious Vapours Abatement Association has arranged for a series of free lectures, with a view to directing public attention to the evils resulting from the present excessive pollution of the air of Manchester and Salford by coal smoke and vapours from chemical works and other places where offensive trades are carried on. The lectures are to be given by Mr. Carter Bell, Dr. Ransome, Mr. Estcourt, and others.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The following gentlemen, having passed the examination held at Bethlem Hospital on Nov. 29th and 30th, will receive the certificate in Psychological Medicine viz., T. B. Hyslop, Bethlem Hospital; James Neil, Warneford House, Oxford; Walter Pearce, Maidenhead; Alan Rigden, County Asylum, Bicton Heath, Shrewsbury; G. M. Robertson, Montague-street, Russell-square; J. Walter Scott, Fareham, Hants; Percy Smith, Bethlem Hospital; G. D. Symes, County Asylum, Dorchester.

GREAT NORTHERN CENTRAL HOSPITAL.—On the 30th ult., Mr. G. C. T. Bartley, M.P., presided over a meeting, at Holloway Hall, which had been called to consider ways and means with regard to the Great Northern Central Hospital, which it is proposed to erect in the Holloway-road. The site has been purchased at a cost of £7000, and £5000 towards the building is in hand; but £43,000 are still required. A committee of thirty, with power to add to their number, was appointed for the special purpose of collecting funds; Mr. Bartley, M.P., being chairman.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—At a meeting of this Association held on the 30th ult., an address was delivered by the president, Dr. B. W. Richardson, on "The Public-house and the Public Health," medical officers of health having received special invitations. At the close of the address a discussion ensued, in which Dr. Norman Kerr, Dr. Pearce, and others took part, and it was agreed to memorialise the Government to institute an inquiry into the extent of disease and mortality produced, directly or indirectly, by the public sale of intoxicating drinks.

ROYAL HOSPITAL FOR INCURABLES.—On the 26th ult. the thirty-second annual meeting of the friends of this institution was held, when the report, which was read by the secretary, Mr. F. Andrew, showed that at the present time 373 persons are dependent on the funds of the charity, about 190 of whom are inmates of the hospital. The year's receipts, including dividends, £2202; deposit at bank, £6180; subscriptions, donations, and bequests, £22,793, amounted to £35,736. Of this sum £11,866 were spent on the hospital, £9920 on pensions, £3391 on general expenses, and £5000 invested, leaving a balance of £5201. During the year a seaside home in connexion with the asylum has been opened at St. Leonards, and to this house 90 of the most suitable cases have been sent in parties of five or six.

ROYAL SOCIETY.—At a meeting on the 30th ult. the following medals were presented:—The Copley Medal to Franz Ernst Neumann of Königsberg, for his researches in theoretical optics and electro-dynamics; the Davy Medal to Jean Charles Galissard de Marignac of Geneva, for his researches on atomic weights; the Rumford Medal to Professor Samuel P. Langley, for his researches on the spectrum by means of the bolometer; a Royal Medal to Mr. Francis Galton, for his statistical inquiries into biological phenomena; and a Royal Medal to Professor Peter Guthrie Tait, for his various mathematical and physical researches. Professor Michael Foster was afterwards elected one of the treasurers, and Professor David Ferrier and Arthur Gamgee, M.D., members of the council, for the ensuing year.

QUEEN'S COLLEGE, BELFAST. — The following scholarships have been awarded:—Fourth year (Anatomy and Physiology): Wm. Weatherup. Third year (Medicine): J. M. Hall, R. W. Haslett. Second year: Hamilton Morton, James Taylor. First year: S. M'C. Killen.

SEASONABLE DONATIONS.—Mr. Edward Kelley, late of York-street, now of 5, Broadway, Westminster, has given through Dr. Fenton, in memory of his late wife, £400 to each of the following institutions: Westminster Hospital, the Western Dispensary, Rochester-row, and Miss Sharman's Orphans' Home, West-square, S.E.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ANNINGSON, BUSHELL, M.D.Cantab., has been reappointed Medical Officer of Health for the Cambridge Urban Sanitary District.

ARUNDELL, SHIRLEY W., M.R.C.S., L.S.A., has been appointed Medical Officer for the Eleventh District of the Wisbeach Union.

ATKINSON, FRANCIS EDWARD, L.R.C.P.Lond., M.R.C.S., has been reappointed Medical Officer of Health for the Haworth, Oakworth, Oxenhope, Silsden, and Skipton Urban Sanitary Districts; and the Keighley, Settle, and Skipton Rural Sanitary Districts.

FRASER, THOMAS, M.A., M.B., has been appointed Assistant-Physician to the Crichton Royal Institution, Dumfries.

HUGHES, R. A., M.R.C.S., L.R.C.P., has been appointed Clinical Assistant in the Skin Department of the North-West London Hospital.

HUNT, EDGAR A., M.R.C.S., L.R.C.P.Ed., has been appointed Surgeon to the Essex and Colchester Hospital.

KARKEEK, P. Q., M.R.C.S., L.S.A., has been appointed Medical Inspector for Torquay, under the Workshops and Factories Act, vice Chilcote, deceased.

LANGLEY, AARON, L.R.C.P.Ed., L.R.C.S., has been appointed Medical Officer for the Eighth District of the St. Saviour's Union.

LING, C. A. S., M.R.C.S., L.S.A., has been appointed Medical Officer for the Twelfth District of the Tendring Union.

LISTON, HENRY, L.R.C.P., L.R.C.S.Ed., has been appointed Honorary Medical Officer to the Sunderland Hospital for Sick Children, vice Mordey Douglas, M.R.C.S., L.R.C.P.Ed., appointed Consultant.

MELVILLE, H. B., M.B., C.M., has been appointed Assistant Physician to the Crichton Royal Institution, Dumfries.

MITCHELL, ROBERT, M.A., M.B., C.M.Edin., late House-Surgeon, Dewsbury, and District General Infirmary, has been appointed House-Surgeon to the Memorial Hospital, Jarrow-on-Tyne.

RAWSON, EDWIN ELSWORTH, L.R.C.P.Ed., M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Thornton Urban Sanitary District, Yorkshire.

STARK, ARTHUR C., M.B., C.M.Ed., has been appointed Medical Officer for the First District of the Alderbury Union.

WATSON, WILLIAM CHARLES, L.R.C.P.Ed., M.R.C.S., has been reappointed Medical Officer of Health for the Hoole Urban Sanitary District, Cheshire.

WILLS, W. A., M.B.Lond., M.R.C.S., has been appointed House-Surgeon to the Victoria Hospital for Children, Chelsea, vice P. D. Turner, M.B.Lond., resigned.

Births, Marriages, and Deaths.

BIRTHS.

FLEURY.—On Oct. 11th, at Montevideo, the wife of Luis A. Fleury, M.D., of a son.

PIRRIE.—On the 26th ult., at Redcliffe-gardens, South Kensington London, the wife of J. M. Gordon Pirrie, M.D., of a son.

MARRIAGE.

WITHERS—BRYSON.—On the 27th ult., at St. Simon's, Southsea, Robert Withers, M.R.C.S., of Lawrence, Otago, New Zealand, to Isabella Jane, eldest daughter of Colonel T. Bryson, Chief Paymaster (retired), Army Pay Department.

DEATH.

SMYTH.—Recently, at Bergamo, Alto, North Italy, Robert Beresford Smyth, M.D., M.S., Surgeon-Major, A.M.D. (retired), aged 61.

N.B.—*A fee of [illegible] for the Insertion of Notices of Births, Deaths,*

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

SCURVY IN SERPENTS.

M. MAGITOT has recently described to the French Académie des Sciences a disease he has observed amongst snakes which is analogous to scurvy, there being inflammation of the mouth, abscesses, hæmorrhages, ulceration, shedding of teeth, cutaneous ecchymoses, and inflammation of the cervical glands. The causes seem to be overcrowding, dampness, cold, and bad hygienic conditions. A bacillus, too, has been found which M. Pasteur looks upon as the morbid agent. Most of the snakes affected with the disease succumb to it; but by timely care and astringent applications to the mucous membrane of the mouth some may be saved.

A Poor Student.—The decision is not a new one. The vaccination instructors are appointed by the Privy Council, and their certificates only are allowed to be accepted by the examining boards.

Enquirens.—Our Students' Number of September last will afford the information desired.

M. O. H.—The report can be obtained of Knight & Co., Fleet-street, E.C.

Enquirens.—Mr. Jukes de Styrap h s written a book on the subject.

FISSURED TONGUE.

To the Editor of THE LANCET.

SIR,—In answer to "A Young Practitioner," I beg to state that I have been successful in treating four or five cases as follows:—The application twice a week of the solid nitrate of silver to the base of each fissure, after the application of a four-per-cent. solution of cocaine, to prevent pain. Internally the biniodide of mercury and potassic iodide. Thus: R. Sol. hydrarg. bichlor., ʒi.; potass. iodid., ʒss.; ferri ammon. citrat., ʒi.; sp. ether. chloric., ʒii.; aquam ad ℥viii. One tablespoonful every four hours.

I am, Sir, your obedient servant,

Nov. 29th, 1886. C. R. ILLINGWORTH, M.D.

To the Editor of THE LANCET.

SIR,—If "A Young Practitioner" in the case of his patient will try the effect of the local application of a solution of nitrate of silver (thirty grains to the ounce), combined with the internal administration of iodide of potassium, in gradually increasing doses, I venture to think he will soon see an improvement. He has not stated whether there is a history of syphilis or not.

I am, Sir, yours truly,

November 30th, 1886. B. H.

"WINES" IN NEW YORK.

DR. CYRUS EDSON, of the New York Health Board, has recently analysed some of the "wines" sold in America; and with regard to the process of manufacture adopted by one prominent firm of extensive growers, he says that dried fruits, such as raisins, currants, and peaches, are macerated with water, to which a certain amount of sugar is added. The mixture is then fermented, and when fermentation is considered sufficiently advanced, it is checked by the addition of salicylic acid, sufficient being added to act as a preservative and prevent further fermentation. This liquor is clarified, coloured, and flavoured to cause it to resemble port, claret, or any desired kind of "vintage" the purchaser may desire. It is satisfactory to learn that Dr. Edson obtained an order for the destruction of 5280 gallons of this compound—wine it cannot be called.

Enquirer (Exmouth) will find what he desires in THE LANCET, vol. II. 1885, p. 881, and vol. i. 1886, p. 609.

CASE OF POISONING BY STRYCHNIA.

To the Editor of THE LANCET.

SIR,—The following notes may be deemed of sufficient interest for publication.

At 8.15 A.M. on Sept. 23rd last, I was summoned to see a woman, who had been moaning and screaming for some time, but was said to have become speechless, unconscious, and seemed very bad. She was a lodger named Margaret B——, aged thirty-five, married but had been deserted by her husband a few days previously. She was lying on her back in bed, dressed, her eyes closed, and could not be roused; her arms were pressed against her sides, and her hands clasped firmly over the chest; the skin was a reddish-purple, and hot; tongue dry, pulse weak (96); respiration short. Every few minutes she would groan, her arms become pressed more firmly against her sides, her legs being rigid and straight, and the soles of the feet arched and back stiff. She could not bend her back, her pulse increased in rapidity, and respiration seemed to stop. There was a peculiar hoarse rattling in the throat, and her face became of a bluish-purple colour. On the mantel-piece I found a teacup empty and dry, lined with a bluish material which tasted bitter, and in the chamber utensil an empty packet of vermin-killer; an attempt to produce emesis failed, and the passage of a tube down her œsophagus brought on a spasm which threatened to end the case; regurgitation in her jugulars was noticed up to the angle of the jaw, and asphyxia almost took place. Chloroform was of certain benefit in two of the spasms, and I procured a one-in-two solution of chloral hydrate and gave her three hypodermic injections of twenty minims each, which reduced the rapidity of the paroxysms and improved her breathing. At 9 o'clock I gave her a final hypodermic injection, making about forty grains in all; she was drowsy, but was made to swallow half an ounce of tannate of glycerine and allowed to sleep. The first needle puncture gave rise to a drop of thick dark venous blood, but the colour rapidly improved. At noon she was still sleeping, but made a slow recovery, and is now in an asylum. I am, Sir, yours truly,

Liverpool, Nov. 9th, 1886. JAS. GRIERSON BROWN, M.B. Lond.

"MORPHIOMANIA."

WITHIN the last few years the disease which goes by the above name has made great strides in France. In the capital its victims almost rival those of alcoholism. At Bellevue a hospital has been opened for the care, and, if possible, the cure of these patients. The cure of it is, however, very rare. It is found that both the use and the deprivation of the drug create a tendency to suicide in the victims; and at Bellevue there are cushioned rooms for some of the patients, and a constant watch kept on all.

B, in the circumstances mentioned, is guilty of no breach of professional etiquette in attending the case.

SANITARY CONDITION OF OXFORD.

To the Editor of THE LANCET.

SIR,—Within the last few days I have been told that the sanitary condition of Oxford in and around the colleges is in a very bad condition, and that more than one case of diphtheria, among the undergraduates, occurred last term. I shall be glad if any brother practitioner can tell me if such is the case, in order that I may give a definite answer to anxious parents. I am, Sir, yours faithfully,

November 25th, 1886. A. T. G. W.

"BARBED WIRE FENCES."

WE have frequently protested against the use of "barbed wire" for fences as being cruel to animals and dangerous to man. It is satisfactory to notice that the Court of Session in Scotland have recently ordered a landowner, who had put up along a public road a wire fence with the top strand barbed, to remove it, as being a danger to the public in the ordinary use of the road.

Dr. R. Rentoul.—The announcement appeared in the 1055th page of our last week's impression.

Francis.—Yes. At the earliest opportunity.

EMIGRATION FOR BELGIAN DOCTORS.

OUR Belgian *confrères* continue to bewail most bitterly the overcrowded state of the profession and the increasing numbers of young men who are yearly entering its portals, only in too many cases to find that it is impossible to secure a sufficient income to live upon. At a recent meeting of the Academy of Medicine a member who had been deputed to report upon a proposed petition to the Government asking for certain concessions for the benefit of rural practitioners—e.g., the formation of provincial medical libraries, the gratuitous distribution of the proceedings of the Academy, the formation of central depôts of surgical instruments, and the assistance of the State in the remuneration of consultants called to patients assisted by the Bureau de Bienfaisance,—after recommending the adoption of this petition, which would somewhat astonish a British Home Secretary, passed on to remark on the overcrowded state of the profession. For this he suggested a remedy, which was no other than emigration to Algeria, a land described by him as a perfect paradise for doctors—at all events, for those who could obtain the post of colonial surgeon, with a salary of 3000 francs, in addition to a house, a garden, and a horse. The only step necessary was to get the Belgian Government to arrange a Franco-medical union with the French Government. If, however, the Algerian medical appointments are as desirable as they appear to M. Barella, it is hardly probable that the members of the profession in France will desire to arrange a union with those in Belgium for the sole purpose of rendering the latter eligible for filling these posts, the number of which is, of course, not unlimited. So our Belgian friends will, it is to be feared, have to look further for a solution of their difficulty.

Mr. F. E. Cane.—According to Wooton's "Guide to the Medical Profession," the following reply was given by the Italian Government to a question similar to that put by our correspondent:—By the law Casati all examinations made and degrees obtained outside the kingdom of Italy are valueless, except in special cases. Holders of the M.D. degree of a foreign university of high standing, who can prove having passed the necessary examinations, may, however, be admitted to the general examinations for the grade to which they aspire. Exemption from these examinations in the case of those who have gained special honours abroad can only be obtained through the Superior Council of Public Instruction, in which case the favour will be sanctioned by Royal decree.

M. G. E. (Cardiff).—The case should be brought under the notice of the College from which the advertiser's diploma was derived.

Duped has not enclosed his card.

THE BRITISH EYE HOSPITAL AT JERUSALEM.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 13th you were good enough to very favourably notice the work carried out under the supervision of the resident medical surgeon, Mr. John Hovell Ogilvie, at the British Ophthalmic Hospital and Hospice of the Order of St. John at Jerusalem. Will you allow me to add that I have to-day received a letter from Sir Edmund and Lady Lechmere, stating that they had just paid a visit to our small hospital, which is situated some little distance outside the city walls, and that they found it in a perfect state of order and discipline, and largely attended by poor suffering patients from all parts of the Holy Land and adjacent countries. You will, I trust, allow me specially to emphasize the fact that no interference whatever is permitted with the religious views of the patients attending, the work being entirely unsectarian, and, except in a very few cases, when grateful patients in a position to pay insist upon making some small offering, the treatment is entirely gratuitous. It may interest your readers to know that the site of the Hospital, at the special request of H.R.H. the Prince of Wales, who is the patron, was generously given by His Imperial Majesty the Sultan.

I am, Sir, your obedient servant,

JOHN H. EASTERBROOK, Hon. Secretary.

Wilkinson-street, S.W., Nov. 16th, 1886.

M. PASTEUR'S METHOD.

Dr. Henry Downes.—We have carefully perused our correspondent's pamphlet, and cannot concur with him in denouncing M. Pasteur's method. We advocate the expectant treatment of this great question. The results of the investigation by the English Commission are being looked forward to with considerable expectation. We may say generally that the results so far obtained by the Commission are not opposed to M. Pasteur's doctrines.

Beaumont Subscriber.—1. Yes.—2. For an answer to this question we must refer our correspondent to our advertising columns.

Dr. J. N. Constable.—The Apothecaries' Society has power to prosecute in such a case.

THE QUEEN'S JUBILEE.

Mr. J. T. Macnamara adds the following suggestion to those made by a correspondent in our last week's issue—viz., that Her Majesty should, in honour of the event, create some few leading members of the profession peers of the realm. By the adoption of this suggestion the profession would at last, even if somewhat tardily, secure from the head of the State that recognition which is eminently its due.

Mr. W. T. Mynors.—The New Act does not alter the law in reference to unqualified assistants.

L.K.Q.C.P.I.—The question is a purely legal one.

CONSULTANTS AND GENERAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—As a general practitioner I can quite understand "Fairplay's" feelings by the treatment he received at the hands of the consultant to whom he introduced his patient. Something very similar occurred to me a short time ago. I sent a patient, who was suffering from deafness of long-standing, to consult an aurist surgeon, to whom I had previously written detailing the case and asking his opinion, at the same time telling him the treatment I had adopted. In due course I received a letter from him, which was in every way apparently satisfactory. He said, "Your prognosis is, I am afraid, about right. I have ordered the chloride of ammonia inhaler to be used again, and also Politzer's bag." Now, I had used this bag regularly for some time, and went as usual to use it again, when, to my utter astonishment, I was informed that the surgeon had written for an inflater for the patient to use herself (a Politzer's bag). Of course, there was nothing left for me to do; it was no use my arguing the point, for the "doctor had ordered it," and I should have been looked upon as only being pecuniarily interested. I maintain that even an apparently simple operation of this kind cannot be satisfactorily carried out by the patient or another unskilled person, and therefore the patient does not derive the benefit intended. I have received very many kindnesses from consultants, and without my seeking them, so that we must not place them all in the same category. I have had on several occasions patients consult physicians, &c., without my knowledge, and without the intention of being in any way discourteous, and the first intimation of such a consultation has been a letter from the consultant. If all consultants would act in the same way towards the general practitioner, it would be much better for the former, and much ill-feeling would be spared the latter.

I am, Sir, your obedient servant,

Dec. 1st, 1886. M.R.C.S.E.

TO YOUNG MOTHERS.

L. P.—The practice of young mothers studying books on first pregnancies is of very doubtful advantage. It will be much more profitable to them to ask their ordinary medical adviser for a little general advice on the subject, to observe the ordinary rules of good health, and otherwise to ignore the subject.

A.M.D.—Our attention has been called to the promotion in question; but we must defer any remarks upon it till next week.

Dr. J. M. Hope (West Australia).—We have had the seeds examined at Kew Gardens. They are certainly those of Abrus precatorius.

A. B. C.—We do not prescribe.

ERRATA.—In the ninth line of the second paragraph of the letter in our last issue, signed "Ye Humble Apothecarie," for "is" read *are*; and in the fifteenth line of the same paragraph for "physician" read *physicians*.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Quinlan, Dublin; Mr. Holmes, London; Dr. Schiltz, Cologne; Dr. Mackenzie Booth; Lord Stanley of Alderley; Mr. Mayo Robson, Leeds; Mr. T. F. Chavasse, Birmingham; Mr. Cresswell Hewett, London; Mr. Grant; Dr. Archie Stockwell, Port Huron; Mr. J. Phillips; Dr. McMunn, Seaford; Dr. Downes, Tiverton; Mr. M. G. Evans, Cardiff; Mr. T. Shepheard, Chester; Mr. G. A. Carpenter, London; Mr. H. F. Bailey, Lee; Mr. Phillips, Birmingham; Mr. Lomas, Vaud; Mr. Bates, New York; Dr. McCambridge, Illinois, U.S.A.; Messrs. The Bradshawe Lecture

ON

BACTERIOLOGY IN ITS RELATIONS TO SURGERY.*

Delivered at the Royal College of Surgeons on Thursday, December 2nd, 1886,

BY HENRY POWER, M.B. LOND., F.R.C.S.

GENTLEMEN,—I propose in the lecture which you have this year done me the high honour of electing me to deliver, in commemoration of Mr. Bradshawe, to place before you the knowledge which has been recently gained by the new science of bacteriology in its relations to surgery. In beginning to work at the subject I immediately found myself confronted with a difficulty which arose from the great confusion that at present exists in regard to nomenclature; and though I probably do great wrong to some of those who are now my auditors, I am convinced that many surgeons have only hazy and indistinct ideas in regard to the classification of these minute beings, and will not be ungrateful to me if I place before them a succinct account of the arrangement that is accepted provisionally by the best authorities in Germany and France as well as in this country, and add a brief outline of the chief facts that are known in regard to their life history.

Truth, says Lord Bacon, is more easily educed from error than from confusion, and no better illustration could be adduced of the maxim than the advantages that are to be gained from even a provisional and incomplete arrangement of these minute organisms into genera and species. Botanists have divided plants into two great groups: phænerogamous plants, with more or less showy flowers and conspicuous organs of generation and fructification; and cryptogams, which propagate in a secret, inconspicuous, and mysterious method by spores. The cryptogams are again divided into those which have a stem and leaves like ferns and those which produce flat expansions on or in which the spores grow, and which are termed thallophytes. The thallophytes were formerly divided into fungi, algæ, and lichens, the broad distinctions between which were that the fungi were destitute of chlorophyll, contained much nitrogen in their composition, and lived on organic substances, whether dead or living, and in air; that algæ contained chlorophyll and lived in water, building up their bodies from inorganic material; and, finally, that the lichens consisted of a mixture of cells, some containing, some destitute of, chlorophyll, nourishing themselves on inorganic substances, and usually living in air. Late researches by Schwendener and others have rather tended to show that the lichens are really algæ which have been invaded by fungi; and, at all events, it has been found that neither lichens nor algæ bear any very important relation to disease, and that those minute organisms which are really influential in the production of a very considerable number of the maladies incident to man and animals, and especially those which are of an infectious or contagious nature, belong to the fungi. Now the fungi have been subdivided by Flügge—looking at them essentially from a hygienic, and not from a botanical, standpoint—into four groups: (1) the fungi proper; (2) the mycetozoa; (3) the blastomycetes; and (4) the Schizomycetes.

Many of the true *fungi* play an important part in the economy of nature, and are of great importance to man in their industrial relations. To mention only two of them. The ustilago carbo forms the black smut of wheat and other cereals, and tilletia caries or bran forms a similar substance in the interior of the grain, and gives a fetid odour to it. Peronospora infestans is the fungus of the potato disease. Botrytis bassiana is the muscardine disease of the silkworm. Uredo or Æcidium (of which puccinia graminis is an example) forms the red rust of wheat, which is perhaps one of the most important and interesting fungi, and the singular history of which in connexion with the barberry is now well known from De Bary's observations. Then come the aspergilli, interesting because some of them can grow in the bodies of warm-blooded animals, and are capable of producing attacks of pneumonia in man and animals. The spores of these fungi are everywhere so abundant that it is only requisite to expose a piece of black bread to the air for a short time, and then place it in a moist warm chamber, for one or other form of aspergillus, according to the temperature, to appear with certainty. The erysiphe-oïdium, or mildews, are found in the grape disease, caused by oïdium tuckeri and oïdium lactis, which forms a white covering to milk, bread, and dung; and closely allied to these are the fungi causing the parasitic skin diseases known as favus, herpes tonsurans, and pityriasis versicolor. The mucors and the penicillium complete the list, these being the most common of all. None of them are of particular importance to the surgeon, except perhaps to the army surgeon, to whom the quality of the food, and especially of the bread, supplied by the commissariat, is a subject of unfailing interest.

The *Mycetozoa* may be passed over, as so little is known in regard to their relation to disease.

The *Blastomycetes* are represented by the yeasts and organised ferments which convert sugar into alcohol and carbonic acid, and the examination of which, in the hands of M. Pasteur, may be said to have led the way to all recent research on the subject of microbes.

From them we pass to the *Schizomycetes*, which have been differently grouped by different observers, and I here exhibit to you the classifications of Zopf and of Flügge, and also of Klein, whose excellent little work on Micro-organisms, just published, should be in everyone's hands. Klein divides the schizomycetes into micrococci, bacteria, bacilli, and spirilla, and each of these he subdivides into those that are septic, those that are zymogenic, those that are chromogenic, and those that are pathogenic. Septic microbes are those which excite, or at least accompany, the putrefaction of organic matters; their action on proteids, as Hoppe-Seyler has pointed out, resembles digestion: the first products being peptones, then leucin, tyrosin, and the fatty acids; and, finally, indol, phenol, scatol, hydrogen sulphide, ammonia, carbonic acid, and water. From putrefying animal substances there may be obtained a material which is certainly not living, for it can dialyse through a membrane, but which is capable of exciting septicæmia when introduced into the healthy body of animals, a condition that must be carefully distinguished from pyæmia. Septic poisons produce an effect commensurate with the quantity of the poison introduced; if the quantity be small, only slight and transient effects are produced; if it be large, the effects are more severe, and vomiting, rigors, spasms, and collapse, ending in death, may occur. Post-mortem examination shows congestion and hæmorrhage of the lungs and intestinal mucous membrane. In pyæmia, on the other hand, a poisonous agent is also introduced into the system, but it so far differs from the poison of septicæmia that it appears to be living and capable of multiplication, so that a very small quantity may prove fatal by the formation of numerous and widespread abscesses. It is possible, however, that, as Klein argues, large open wounds may become the seat of the multiplication of various organisms, which, by producing a septic poison, may produce septicæmia when absorbed in sufficient quantities.

Zymogenic Microbes.—The term zymogenic action is only another term for the induction of fermentation, and upon the whole of this subject a flood of light has been thrown by the labours of Pasteur. The chief forms are (1) the alcoholic, (2) the lactic, (3) the viscous, (4) the acetic, (5) the ammoniacal, (6) the butyric, and (7) the putrid fermentation. The agents are always microbes destitute of chlorophyll, and are generally anaerobic, obtaining the oxygen they require for growth and activity from the oxidised compounds in the liquid in which they grow. The micrococcus of urea and that of the phosphorescence of putrid meat and fish are, however, aerobic. The ammoniacal and the putrid fermentations are of the greatest interest to the surgeon. The former is exemplified in the action of the micrococcus ureæ and the bacillus ureæ in converting urea in ammonium carbonate. The micrococcus ureæ appears, when cultivated, in the form of minute spherical cells, either separate or united to diplococci, or in tetrads or in chains. They do not fluidify gelatine. The development of the microbe is not interfered with by the alkalinity of the fluid, and it can continue when the proportion of ammonium carbonate is as much as 13 per cent. The most favourable temperature for its development is from 30° to 38° C. The bacillus ureæ is a short

Medical Diary for the ensuing Week.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

SCURVY IN SERPENTS.

M. MAGITOT has recently described to the French Académie des Sciences a disease he has observed amongst snakes which is analogous to scurvy, there being inflammation of the mouth, abscesses, hæmorrhages, ulceration, shedding of teeth, cutaneous ecchymoses, and inflammation of the cervical glands. The causes seem to be overcrowding, dampness, cold, and bad hygienic conditions. A bacillus, too, has been found which M. Pasteur looks upon as the morbid agent. Most of the snakes affected with the disease succumb to it; but by timely care and astringent applications to the mucous membrane of the mouth some may be saved.

A Poor Student.—The decision is not a new one. The vaccination instructors are appointed by the Privy Council, and their certificates only are allowed to be accepted by the examining boards.

Enquirens.—Our Students' Number of September last will afford the information desired.

M. O. H.—The report can be obtained of Knight & Co., Fleet-street, E.C.

Enquirens.—Mr. Jukes de Styrap has written a book on the subject.

FISSURED TONGUE.

To the Editor of THE LANCET.

SIR,—In answer to "A Young Practitioner," I beg to state that I have been successful in treating four or five cases as follows:—The application twice a week of the solid nitrate of silver to the base of each fissure, after the application of a four-per-cent. solution of cocaine, to prevent pain. Internally the bichloride of mercury and potassic iodide. Thus: R. Sol. hydrarg. bichlor., ℥i.; potass. iodid., 3ss.; ferri ammon. citrat., ʒi.; sp. ether. chloric., ʒii.; aquam ad ℥viii. One tablespoonful every four hours.

I am, Sir, your obedient servant,
Nov. 29th, 1886. C. R. ILLINGWORTH, M.D.

To the Editor of THE LANCET.

SIR,—If "A Young Practitioner" in the case of his patient will try the effect of the local application of a solution of nitrate of silver (thirty grains to the ounce), combined with the internal administration of iodide of potassium, in gradually increasing doses, I venture to think he will soon see an improvement. He has not stated whether there is a history of syphilis or not.

I am, Sir, yours truly,
November 30th, 1886. B. H.

"WINES" IN NEW YORK.

DR. CYRUS EDSON, of the New York Health Board, has recently analysed some of the "wines" sold in America; and with regard to the process of manufacture adopted by one prominent firm of extensive growers, he says that dried fruits, such as raisins, currants, and peaches, are macerated with water, to which a certain amount of sugar is added. The mixture is then fermented, and when fermentation is considered sufficiently advanced, it is checked by the addition of salicylic acid, sufficient being added to act as a preservative and prevent further fermentation. This liquor is clarified, coloured, and flavoured to cause it to resemble port, claret, or any desired kind of "vintage" the purchaser may desire. It is satisfactory to learn that Dr. Edson obtained an order for the destruction of 5280 gallons of this compound—wine it cannot be called.

Enquirer (Exmouth) will find what he desires in THE LANCET, vol. ii. 1885, p. 881, and vol. i. 1886, p. 609.

CASE OF POISONING BY STRYCHNIA.

To the Editor of THE LANCET.

SIR,—The following notes may be deemed of sufficient interest for publication.

At 8.15 A.M. on Sept. 23rd last, I was summoned to see a woman, who had been moaning and screaming for some time, but was said to have become speechless, unconscious, and seemed very bad. She was a lodger named Margaret B——, aged thirty-five, married but had been deserted by her husband a few days previously. She was lying on her back in bed, dressed, her eyes closed, and could not be roused; her arms were pressed against her sides, and her hands clasped firmly over the chest; the skin was a reddish-purple, and hot; tongue dry, pulse weak (96); respiration short. Every few minutes she would groan, her arms become pressed more firmly against her sides, her legs being rigid and straight, and the soles of the feet arched and back stiff. She could not bend her back, her pulse increased in rapidity, and respiration seemed to stop. There was a peculiar hoarse rattling in the throat, and her face became of a bluish-purple colour. On the mantel-piece I found a teacup empty and dry, lined with a bluish material which tasted bitter, and in the chamber utensil an empty packet of vermin-killer; an attempt to produce emesis failed, and the passage of a tube down her œsophagus brought on a spasm which threatened to end the case; regurgitation in her jugulars was noticed up to the angle of the jaw, and asphyxia almost took place. Chloroform was of certain benefit in two of the spasms, and I procured a one-in-two solution of chloral hydrate and gave her three hypodermic injections of twenty minims each, which reduced the rapidity of the paroxysms and improved her breathing. At 9 o'clock I gave her a final hypodermic injection, making about forty grains in all; she was drowsy, but was made to swallow half an ounce of tannate of glycerine and allowed to sleep. The first needle puncture gave rise to a drop of thick dark venous blood, but the colour rapidly improved. At noon she was still sleeping, but made a slow recovery, and is now in an asylum.

I am, Sir, yours truly,

Liverpool, Nov. 9th, 1886. JAS. GRIERSON BROWN, M.B. Lond.

"MORPHIOMANIA."

WITHIN the last few years the disease which goes by the above name has made great strides in France. In the capital its victims almost rival those of alcoholism. At Bellevue a hospital has been opened for the care, and, if possible, the cure of these patients. The cure of it is, however, very rare. It is found that both the use and the deprivation of the drug create a tendency to suicide in the victims; and at Bellevue there are cushioned rooms for some of the patients, and a constant watch kept on all.

B, in the circumstances mentioned, is guilty of no breach of professional etiquette in attending the case.

SANITARY CONDITION OF OXFORD.

To the Editor of THE LANCET.

SIR,—Within the last few days I have been told that the sanitary condition of Oxford in and around the colleges is in a very bad condition, and that more than one case of diphtheria, among the undergraduates, occurred last term. I shall be glad if any brother practitioner can tell me if such is the case, in order that I may give a definite answer to anxious parents.

I am, Sir, yours faithfully,

November 25th, 1886. A. T. G. W.

"BARBED WIRE FENCES."

WE have frequently protested against the use of "barbed wire" for fences as being cruel to animals and dangerous to man. It is satisfactory to notice that the Court of Session in Scotland have recently ordered a landowner, who had put up along a public road a wire fence with the top strand barbed, to remove it, as being a danger to the public in the ordinary use of the road.

Dr. R. Rentoul.—The announcement appeared in the 1055th page of our last week's impression.

Francis.—Yes. At the earliest opportunity.

EMIGRATION FOR BELGIAN DOCTORS.

OUR Belgian *confrères* continue to bewail most bitterly the overcrowded state of the profession and the increasing numbers of young men who are yearly entering its portals, only in too many cases to find that it is impossible to secure a sufficient income to live upon. At a recent meeting of the Academy of Medicine a member who had been deputed to report upon a proposed petition to the Government asking for certain concessions for the benefit of rural practitioners—e.g., the formation of provincial medical libraries, the gratuitous distribution of the proceedings of the Academy, the formation of central depôts of surgical instruments, and the assistance of the State in the remuneration of consultants called to patients assisted by the Bureau de Bienfaisance,—after recommending the adoption of this petition, which would somewhat astonish a British Home Secretary, passed on to remark on the overcrowded state of the profession. For this he suggested a remedy, which was no other than emigration to Algeria, a land described by him as a perfect paradise for doctors—at all events, for those who could obtain the post of colonial surgeon, with a salary of 3000 francs, in addition to a house, a garden, and a horse. The only step necessary was to get the Belgian Government to arrange a Franco-medical union with the French Government. If, however, the Algerian medical appointments are as desirable as they appear to M. Barella, it is hardly probable that the members of the profession in France will desire to arrange a union with those in Belgium for the sole purpose of rendering the latter eligible for filling these posts, the number of which is, of course, not unlimited. So our Belgian friends will, it is to be feared, have to look further for a solution of their difficulty.

Mr. F. E. Cane.—According to Wooton's "Guide to the Medical Profession," the following reply was given by the Italian Government to a question similar to that put by our correspondent:—By the law Casati all examinations made and degrees obtained outside the kingdom of Italy are valueless, except in special cases. Holders of the M.D. degree of a foreign university of high standing, who can prove having passed the necessary examinations, may, however, be admitted to the general examinations for the grade to which they aspire. Exemption from these examinations in the case of those who have gained special honours abroad can only be obtained through the Superior Council of Public Instruction, in which case the favour will be sanctioned by Royal decree.

M. G. E. (Cardiff).—The case should be brought under the notice of the College from which the advertiser's diploma was derived.

Duped has not enclosed his card.

THE BRITISH EYE HOSPITAL AT JERUSALEM.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 13th you were good enough to very favourably notice the work carried out under the supervision of the resident medical surgeon, Mr. John Hovell Ogilvie, at the British Ophthalmic Hospital and Hospice of the Order of St. John at Jerusalem. Will you allow me to add that I have to-day received a letter from Sir Edmund and Lady Lechmere, stating that they had just paid a visit to our small hospital, which is situated some little distance outside the city walls, and that they found it in a perfect state of order and discipline, and largely attended by poor suffering patients from all parts of the Holy Land and adjacent countries. You will, I trust, allow me specially to emphasize the fact that no interference whatever is permitted with the religious views of the patients attending, the work being entirely unsectarian, and, except in a very few cases, when grateful patients in a position to pay insist upon making some small offering, the treatment is entirely gratuitous. It may interest your readers to know that the site of the Hospital, at the special request of H.R.H. the Prince of Wales, who is the patron, was generously given by His Imperial Majesty the Sultan.

I am, Sir, your obedient servant,

JOHN H. EASTERBROOK, Hon. Secretary.

Wilkinson-street, S.W., Nov. 16th, 1886.

M. PASTEUR'S METHOD.

Dr. Henry Downes.—We have carefully perused our correspondent's pamphlet, and cannot concur with him in denouncing M. Pasteur's method. We advocate the expectant treatment of this great question. The results of the investigation by the English Commission are being looked forward to with considerable expectation. We may say generally that the results so far obtained by the Commission are not opposed to M. Pasteur's doctrines.

Beaumont Subscriber.—1. Yes.—2. For an answer to this question we must refer our correspondent to our advertising columns.

Dr. J. N. Constable.—The Apothecaries' Society has power to prosecute in such a case.

THE QUEEN'S JUBILEE.

Mr. J. T. Macnamara adds the following suggestion to those made by a correspondent in our last week's issue—viz., that Her Majesty should, in honour of the event, create some few leading members of the profession peers of the realm. By the adoption of this suggestion the profession would at last, even if somewhat tardily, secure from the head of the State that recognition which is eminently its due.

Mr. W. T. Mynors.—The New Act does not alter the law in reference to unqualified assistants.

L.K.Q.C.P.I.—The question is a purely legal one.

CONSULTANTS AND GENERAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—As a general practitioner I can quite understand "Fairplay's" feelings by the treatment he received at the hands of the consultant to whom he introduced his patient. Something very similar occurred to me a short time ago. I sent a patient, who was suffering from deafness of long-standing, to consult an aural surgeon, to whom I had previously written detailing the case and asking his opinion, at the same time telling him the treatment I had adopted. In due course I received a letter from him, which was in every way apparently satisfactory. He said, "Your prognosis is, I am afraid, about right. I have ordered the chloride of ammonia inhaler to be used again, and also Politzer's bag." Now, I had used this bag regularly for some time, and went as usual to use it again, when, to my utter astonishment, I was informed that the surgeon had written for an inflater for the patient to use herself (a Politzer's bag). Of course, there was nothing left for me to do; it was no use my arguing the point, for the "doctor had ordered it," and I should have been looked upon as only being pecuniarily interested. I maintain that even an apparently simple operation of this kind cannot be satisfactorily carried out by the patient or another unskilled person, and therefore the patient does not derive the benefit intended. I have received very many kindnesses from consultants, and without my seeking them, so that we must not place them all in the same category. I have had on several occasions patients consult physicians, &c., without my knowledge, and without the intention of being in any way discourteous, and the first intimation of such a consultation has been a letter from the consultant. If all consultants would act in the same way towards the general practitioner, it would be much better for the former, and much ill-feeling would be spared the latter.

I am, Sir, your obedient servant,

Dec. 1st, 1886. M.R.C.S.E.

TO YOUNG MOTHERS.

L. P.—The practice of young mothers studying books on first pregnancies is of very doubtful advantage. It will be much more profitable to them to ask their ordinary medical adviser for a little general advice on the subject, to observe the ordinary rules of good health, and otherwise to ignore the subject.

A.M.D.—Our attention has been called to the promotion in question; but we must defer any remarks upon it till next week.

Dr. J. M. Hope (West Australia).—We have had the seeds examined at Kew Gardens. They are certainly those of Abrus precatorius.

A. B. C.—We do not prescribe.

ERRATA.—In the ninth line of the second paragraph of the letter in our last issue, signed "Ye Humble Apothecarie," for "is" read *are*; and in the fifteenth line of the same paragraph for "physician" read *physicians*.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Quinlan, Dublin; Mr. Holmes, London; Dr. Schiltz, Cologne; Dr. Mackenzie Booth; Lord Stanley of Alderley; Mr. Mayo Robson, Leeds; Mr. T. F. Chavasse, Birmingham; Mr. Cresswell Hewett, London; Mr. Grant; Dr. Archie Stockwell, Port Huron; Mr. J. Phillips; Dr. McMunn, Seafield; Dr. Downes, Tiverton; Mr. M. G. Evans, Cardiff; Mr. T. The Bradshawe Lecture

ON

BACTERIOLOGY IN ITS RELATIONS TO SURGERY.*

Delivered at the Royal College of Surgeons on Thursday, December 2nd, 1886,

BY HENRY POWER, M.B. LOND., F.R.C.S.

GENTLEMEN,—I propose in the lecture which you have this year done me the high honour of electing me to deliver, in commemoration of Mr. Bradshawe, to place before you the knowledge which has been recently gained by the new science of bacteriology in its relations to surgery. In beginning to work at the subject I immediately found myself confronted with a difficulty which arose from the great confusion that at present exists in regard to nomenclature; and though I probably do great wrong to some of those who are now my auditors, I am convinced that many surgeons have only hazy and indistinct ideas in regard to the classification of these minute beings, and will not be ungrateful to me if I place before them a succinct account of the arrangement that is accepted provisionally by the best authorities in Germany and France as well as in this country, and add a brief outline of the chief facts that are known in regard to their life history.

Truth, says Lord Bacon, is more easily educed from error than from confusion, and no better illustration could be adduced of the maxim than the advantages that are to be gained from even a provisional and incomplete arrangement of these minute organisms into genera and species. Botanists have divided plants into two great groups: phænerogamous plants, with more or less showy flowers and conspicuous organs of generation and fructification: and cryptogams, which propagate in a secret, inconspicuous, and mysterious method by spores. The cryptogams are again divided into those which have a stem and leaves like ferns and those which produce flat expansions on or in which the spores grow, and which are termed thallophytes. The thallophytes were formerly divided into fungi, algæ, and lichens, the broad distinctions between which were that the fungi were destitute of chlorophyll, contained much nitrogen in their composition, and lived on organic substances, whether dead or living, and in air; that algæ contained chlorophyll and lived in water, building up their bodies from inorganic material; and, finally, that the lichens consisted of a mixture of cells, some containing, some destitute of, chlorophyll, nourishing themselves on inorganic substances, and usually living in air. Late researches by Schwendener and others have rather tended to show that the lichens are really algæ which have been invaded by fungi; and, at all events, it has been found that neither lichens nor algæ bear any very important relation to disease, and that those minute organisms which are really influential in the production of a very considerable number of the maladies incident to man and animals, and especially those which are of an infectious or contagious nature, belong to the fungi. Now the fungi have been subdivided by Flügge—looking at them essentially from a hygienic, and not from a botanical, standpoint—into four groups: (1) the fungi proper; (2) the mycetozoa; (3) the blastomycetes; and (4) the Schizomycetes.

Many of the true *fungi* play an important part in the economy of nature, and are of great importance to man in their industrial relations. To mention only two of them. The ustilago carbo forms the black smut of wheat and other cereals, and tilletia caries or bran forms a similar substance in the interior of the grain, and gives a fetid odour to it. Peronospora infestans is the fungus of the potato disease. Botrytis bassiana is the muscardine disease of the silkworm. Uredo or Æcidium (of which puccinia graminis is an example) forms the red rust of wheat, which is perhaps one of the most important and interesting fungi, and the singular history of which in connexion with the barberry is now well known from De Bary's observations. Then come the aspergilli, interesting because some of them can grow in the bodies of warm-blooded animals, and are capable of producing attacks of pneumonia in man and animals. The spores of these fungi are everywhere so abundant that it is only requisite to expose a piece of black bread to the air for a short time, and then place it in a moist warm chamber, for one or other form of aspergillus, according to the temperature, to appear with certainty. The erysiphe-oïdium, or mildews, are found in the grape disease, caused by oïdium tuckeri and oïdium lactis, which forms a white covering to milk, bread, and dung; and closely allied to these are the fungi causing the parasitic skin diseases known as favus, herpes tonsurans, and pityriasis versicolor. The mucors and the penicillium complete the list, these being the most common of all. None of them are of particular importance to the surgeon, except perhaps to the army surgeon, to whom the quality of the food, and especially of the bread, supplied by the commissariat, is a subject of unfailing interest.

The *Mycetozoa* may be passed over, as so little is known in regard to their relation to disease.

The *Blastomycetes* are represented by the yeasts and organised ferments which convert sugar into alcohol and carbonic acid, and the examination of which, in the hands of M. Pasteur, may be said to have led the way to all recent research on the subject of microbes.

From them we pass to the *Schizomycetes*, which have been differently grouped by different observers, and I here exhibit to you the classifications of Zopf and of Flügge, and also of Klein, whose excellent little work on Micro-organisms, just published, should be in everyone's hands. Klein divides the schizomycetes into micrococci, bacteria, bacilli, and spirilla, and each of these he subdivides into those that are septic, those that are zymogenic, those that are chromogenic, and those that are pathogenic. Septic microbes are those which excite, or at least accompany, the putrefaction of organic matters; their action on proteids, as Hoppe-Seyler has pointed out, resembles digestion: the first products being peptones, then leucin, tyrosin, and the fatty acids; and, finally, indol, phenol, scatol, hydrogen sulphide, ammonia, carbonic acid, and water. From putrefying animal substances there may be obtained a material which is certainly not living, for it can dialyse through a membrane, but which is capable of exciting septicæmia when introduced into the healthy body of animals, a condition that must be carefully distinguished from pyæmia. Septic poisons produce an effect commensurate with the quantity of the poison introduced; if the quantity be small, only slight and transient effects are produced; if it be large, the effects are more severe, and vomiting, rigors, spasms, and collapse, ending in death, may occur. Post-mortem examination shows congestion and hæmorrhage of the lungs and intestinal mucous membrane. In pyæmia, on the other hand, a poisonous agent is also introduced into the system, but it so far differs from the poison of septicæmia that it appears to be living and capable of multiplication, so that a very small quantity may prove fatal by the formation of numerous and widespread abscesses. It is possible, however, that, as Klein argues, large open wounds may become the seat of the multiplication of various organisms, which, by producing a septic poison, may produce septicæmia when absorbed in sufficient quantities.

Zymogenic Microbes.—The term zymogenic action is only another term for the induction of fermentation, and upon the whole of this subject a flood of light has been thrown by the labours of Pasteur. The chief forms are (1) the alcoholic, (2) the lactic, (3) the viscous, (4) the acetic, (5) the ammoniacal, (6) the butyric, and (7) the putrid fermentation. The agents are always microbes destitute of chlorophyll, and are generally anaerobic, obtaining the oxygen they require for growth and activity from the oxidised compounds in the liquid in which they grow. The micrococcus of urea and that of the phosphorescence of putrid meat and fish are, however, aerobic. The ammoniacal and the putrid fermentations are of the greatest interest to the surgeon. The former is exemplified in the action of the micrococcus ureæ and the bacillus ureæ in converting urea in ammonium carbonate. The micrococcus ureæ appears, when cultivated, in the form of minute spherical cells, either separate or united to diplococci, or in tetrads or in chains. They do not fluidify gelatine. The development of the microbe is not interfered with by the alkalinity of the fluid, and it can continue when the proportion of ammonium carbonate is as much as 13 per cent. The most favourable temperature for its development is from 30° to 33° C. The bacillus ureæ is a short

plump bacillus with rounded poles, and is about twice as long as wide. Growth only takes place on the surface exposed to air, and, like the micrococcus, its action, as is now well known, is to decompose urea into ammonium carbonate with absorption of water: $CONH_2\ NH_2 + 2H_2O = CO_2\ 2\ (NH_4)$.

Chromogenic Microbes.—The term "chromogenic" is applied to those which develop colouring matter. This is sometimes soluble, sometimes insoluble, in water. The microbes are always aerobic. The most remarkable forms of chromogenic micrococcus is the M. prodigiosus, or red snow. The most remarkable of chromogenic bacteria are the bacterium rubescens of Ray Lankester,[1] which appears in vessels containing decomposing astaci and which is noticeable for its pleomorphism, and the bacterium cyanogenum, which is the cause of blue milk.

Pathogenic Microbes.—The pathogenic organisms are those which, as their name implies, are capable of generating disease; and the evidence on which their disease-producing powers rest is, it must be admitted, sufficiently satisfactory, for no microbe is regarded as the cause of a disease unless it is, in the first place, found to be constantly present in that disease, either in the blood or in the tissues; secondly, that when carefully isolated and cultivated, it can, when introduced into the body of a healthy animal, give rise to the original disease, and be again found in quantity in the body.

That the air contains a large number of particles floating in it has been shown by many observers, amongst whom Cunningham in India, Salisbury in America, Sanderson in England, Robin in France, and especially Miquel, of the Montsouris Observatory, may be mentioned. The apparatus of Miquel consisted of a S-shaped tube with a vane, so that the open mouth was always directed to the windward quarter. In the interior was an inverted funnel, the small extremity of which almost impinged on a horizontal plate of glass, the surface of which was rendered glutinous or adhesive by covering it with a solution of glucose in glycerine, and which was replaced from time to time. Examination of this plate showed some inorganic substances—such as fine crystals and iron; and many organic particles—such as vegetable cells and fibres, pollen grains, grains of starch, the spores of penicillium, aspergillus, coremium, and some botrytidæ, septonema, the septate ends of leptotrichum, trichostemium, septosporium, helicotrichum, vibrios, and many other spores; and, lastly, various animal substances—such as the scales of butterflies and moths, particles of wool and feathers, and also microbes. He has given an excellent graphic representation of the number of microbes contained in the air blowing from different quarters over the Observatory of Montsouris, which is situated to the south of Paris. From this it appears that the air picks up in its passage across Paris in the course of half an hour three times the number of microbes it contains when blowing over the country. In the water, as might be expected, they are still more numerous, and nothing shows more clearly the effects of the drainage of a large city into a river than the fact that at Bercy on the Seine, above Paris, the number of microbes was about 5,000,000, whilst at Asnières, below Paris, it was nearly 13,000,000 per cubic litre, whilst a litre of rain-water contained 248,000. That these particles not only enter our bodies, but are arrested and retained in them, is shown by the conclusive yet simple experiment of Tyndall, who, by transmitting a beam of electric light through air before and after it has been respired, showed that, however thickly populated before, it is entirely free from organic and inorganic particles after it has once passed through our lungs. It may be incidentally mentioned that many microbes exist under ordinary circumstances on or in our bodies. Such are those which Bizzozero has shown fasten on our dead and desquamating epithelial scales, the leptothrix found between the fingers and toes, the bacillus of the smegma preputii, the numerous micro-organisms found between the teeth in all but those who are exceptionally cleanly in their habits, and which have been described by Miller and Lewis, and the various microbes of the intestines.

In regard to the life history of the schizomycetes, it may be said that they are all microscopic, and some of them only just visible under the highest powers. They are composed of a special form, named by Nencki mycoprotein, which is destitute of sulphur and phosphorus, and is not precipitated by alcohol. Some move; others are motionless. Some form a kind of gelatinous capsule, which, fusing with those of adjacent microbes, produce a zoogloea. Many require a special soil. V. Jacksch has shown that the micrococcus ureæ can grow on ammonium succinate and lactate and malate, but not on ammonium formiate, acetate, or butyrate. Some require oxygen—the aerobic microbes of Pasteur; others can grow without access of free oxygen, obtaining that element from the soil on or in which they grow. Most grow best at some definite temperature. The multiplication of the schizomycetes takes place by fission only, or by fission and by the formation of spores. The separation and isolation of these micro-organisms is a matter of much difficulty, but it can be effected by Pasteur's fluid method, or, still better, by Koch's method of plate culture and growth in sterilised peptone gelatine and agar agar.

True Breeding.—A considerable divergence of opinion still exists as to whether the various forms of microbes are really specifically distinct from one another, and whether successive generations so far retain their characters that they may be held, supposing the conditions to be similar, to breed true. This is obviously of importance from a sanitary and hygienic point of view, for, as Mittenzweig has well expressed it, if a form of microbe which has been ascertained to possess injurious qualities can be developed out of a harmless form, it is impossible that we should ever be able to establish sanitary measures that are of the least value, since we are always surrounded by millions of germs which may at any moment develop into a dangerous enemy. On the other hand, if these prove to be specific varieties, it is perfectly possible that, by gaining an accurate knowledge of its life history, its mode of origin, its favourite haunts, its mode of attack, the conditions of temperature and soil which are most favourable to its growth, its fruiting, the germination of its spores, and the like, we may learn to know our enemy, and may adopt precautionary measures which shall have for their object the extermination of the species in question.

Micrococci.—The pathogenic micrococci which are of interest to the surgeon are (1) those of the pus of open wounds, (2) the micrococcus of erysipelas, (3) the micrococcus of gonorrhœa, (4) the micrococcus of acute infectious myelitis, and (5) the micrococcus of progressive necrosis. The bacilli are (1) those of syphilis, (2) those of tubercle and lepra, (3) those of tetanus, (4) those of anthrax, (5) those of ulcerative stomatitis, and (6) those of foot-and-mouth disease.

Micrococcus.—Several forms of micrococcus are associated with disease in man. First, the staphylococcus pyogenes aureus. This was first recognised by Ogston in 1881. It appears in the form of spheroidal cells 0·87μ in diameter, which may either be isolated or twin, or arranged in groups of four, or in the form of a short chain of three or four elements, but sometimes also in large irregular groups, from which its name is derived. The colonies fluidify gelatine, but not agar-agar. When they are in contact with air they assume a bright yellow tint, but if covered with a layer of oil they remain white. This is the most common microbe found in collections of pus in man, and much evidence has been accumulated to show that either they or their excreta are the active agents in the production of abscesses; for, in the first place, Rosenbach and Passet have demonstrated that abscesses do not, as has hitherto been generally believed, necessarily result from the subcutaneous injection of even highly irritating substances—such, for example, as the oil of turpentine—unless some microbe be present; whilst certain forms of microbes are almost constantly found in abscesses, and some kinds of suppuration appear to be especially induced by the staphylococcus aureus. Thus it may be regarded as peculiarly apt to occasion boils, acute abscesses, and empyema. It is found also in acute osteo-myelitis, though whether it is the exclusive cause of this disease is not certainly known. Other affections in which it has been noticed are metastatic affections, pyæmia, and ulcerative endocarditis. Mr. Hartridge and myself found it in the pus of a hypopyon. The poisonous qualities this kind of pus microbe possesses is well shown by an experiment made by Garré and quoted by Flügge, in which a little of the cultivated micrococcus rubbed into the completely intact and healthy skin of the arm irritated the excretory ducts of the glands of the skin and occasioned a widespread group of furuncles. Other forms of staphylococcus have been described by late observers under the names of staphylococcus pyogenes

[1] Mic. Journal, 1877.

albus, citreus, and tenuis, which differ in the two former cases in the colour assumed by culture colonies, and in the latter by the slightly larger size of the cocci and their disposition to exhibit two dark poles and clear equator. The citreus and tenuis forms are stated each to occur in about 10 per cent. of the pus removed from abscesses. Micrococci of pyæmia and of septicæmia have been described as occurring in the rabbit. Those of pyæmia were obtained from animals into which maceration fluid had been injected; those of septicæmia from those in which fresh meat infusion has been injected. Pyæmic micrococci are round; septicæmic are oval: the former mere points, only $\frac{1}{150000}$th of an inch in diameter; the latter large, $\frac{1}{25000}$th. Pyæmic micrococci cause strong infiltration at the point of inoculation. Peritonitis, metastatic abscesses in lungs and liver, and the capillaries contain heaps of micrococcus masses with blood-corpuscles enclosed, and there are many thrombi. Septicæmic micrococci cause no coagulation of the blood, never surround the blood-corpuscles, but push them to one side. There is no peritonitis; the blood vessels are often filled with them.

Although the purulent discharges of gonorrhœa and the purulent ophthalmia of new-born children were examined by many competent observers with a view of discovering the active agents producing these diseases, it was not till the technical methods of Koch had been introduced that any success attended the efforts made for the discovery of these agents. In 1879, however, Neisser first demonstrated the existence of a micrcbe, which has been recognised by nearly all microscopists, and is evidently intimately connected with the whole group of purulent and contagious diseases of mucous membranes. In the following year Bokai and Finkelstein obtained pure cultures of this micrococcus in the course of two or three weeks, and on introducing a small portion of such cultures into the male urethra an acute attack of gonorrhœa rapidly followed, though when a little eucalyptus oil had been added to the culture, which killed the micrococci, no effects were observed. A similar experiment was performed by Bockhart on a general paralytic. Haab found that the cocci of purulent ophthalmia were absolutely identical with those of gonorrhœa. According to Cornil and Babes, the microbes of gonorrhœa, when fresh, are small spheroidal bodies about four micromillimetres in diameter, which appear to possess some power of motion. They are often arranged in pairs, or even in tetrads, the opposed surfaces being then somewhat flattened. Cornil and Babes believe they have recognised two forms, one a little larger than the other: the latter are disposed in heaps outside the cells; the former are within the cells. They colour easily with strongly staining agents, as methyl violet and fuchsin, but do not stain when treated on Gram's plan. They are found in the epithelial cells, both attached and free, and in the pus cells. The gonorrhœal pus of the male usually contains nothing but micrococci; but that from the female, obtained or collected from the vulva, at the orifice of the urethra, and in the vagina, contains long filaments like those of leptothrix buccalis, and masses of large spores which fill the pavement cells of the membrane. The best, the fullest, and the most recent account of this form of micrococcus has been given by Bumm, whose description I shall follow. Bumm's experiments were made exclusively upon the conjunctiva, which, as he points out, presents special advantages for experiments of this kind; for, in the first place, it is very easily infected; the infection attacks the whole surface simultaneously, and does not slowly spread from point to point; the moment of the commencement of the inflammatory reaction can be precisely noticed, and a portion can without difficulty or harm be excised for examination. There can be no doubt that a very small quantity of the gonorrhœal pus containing micrococci is capable of spreading the disease, and the natural and healthy moist surfaces of the conjunctiva and of the urethra seem to be well adapted for their growth and multiplication, so that they appear in great numbers in the course of twenty-four hours. Whilst other forms of micrococci, if they enter the eye, are unable to effect a lodgment, but are washed away by the tears or urine, the gonococcus cleaves, as Bumm remarks, with an eminently invasive force, to the superficial epithelial cells and the soft protoplasmic substance they contain: they then grow down for the most part between the epithelial cells till they reach the papillary surface of the mucous membrane, and at the end of the second day of infection the whole epithelial investment is completely beset with diplococci. The membrane now begins to present signs of reaction, swarms of white corpuscles escape from the blood vessels and make their way between the tissue elements till they arrive at the surface of the epithelial investment. The cells of this layer, already disturbed in their arrangement by the growth of the fungus, become further separated by the intrusion of the white corpuscles and pus cells, and may even be raised in flakes and detached by the movements of the lids, leading to capillary hæmorrhages between the epithelium and connective tissue. In the event of a croupous exudation forming, the gonococci form rows and heaps between the fibrinous network and the lymphoid cells. In the case of the eye the disease stops suddenly at the limbus corneæ and at the margin of the lids, and when the epithelial investment is broken down the microbes seem to have little power of penetrating the papillary tissue. They do, however, extend along the fibres of the fibrous tissue, and where these separate from each other form little colonies not exceeding the size of the area of a divided capillary. Coincidently the phenomena of inflammation increase in intensity, the round cell infiltration extends to a depth of 2 mm. beneath the surface of the mucous membrane, and the cells become tightly packed, and at this time the suppuration stage of the disease is fully developed. In the course of about four days, when the conditions are favourable, a renovation of the epithelial coat takes place, commencing from the scattered remains of the old epithelium; a single layer is first formed, and by proliferation of the cells of this, a second and a third are formed beneath the first, the cells being flattened with fusiform processes. The development of the microbes now seems to terminate, though it may recommence, and solid rods of cells dip into the subjacent tissue, reminding the observer of the growing zone of cancroid. The gonococci quickly die when introduced into the tissue of the cutis, which explains the negative results formerly obtained by the syphilographers, and Bumm considers on this ground that the statements of those who have found gonococcus in the knee-joint and lymphatic glands require corroboration. No doubt they had a micrococcus before them, but no evidence has been afforded that it was *gonococcus*. He has himself found in the pus of acute bubo diplococci, which, however, both by their staining with Gram's methods and their mode of growth when cultivated, proved to be streptococcus aureus. In this case the staphylococcus which is frequent in gonorrhœal pus had entered through erosions of the prepuce or of the urethra, and had occasioned the suppuration of the gland.

I need hardly say how valuable a knowledge of these organisms has proved in the prevention of a terrible disease—the purulent ophthalmia of new-born infants. Formerly of common occurrence in all lying-in institutions, it is now, or perhaps I ought to say it might be now, by the use of well-known precautionary measures, entirely abolished. Sexual connexion should not take place during the last week or two preceding delivery. The hands and (if such are required) the instruments of the accoucheur should be absolutely clean. If there is the least doubt as to the existence of any discharge in father or mother, the vagina may be washed out with a dilute solution of corrosive sublimate (1 in 10,000); and if any discharge show itself in the infant, it should be promptly met and arrested by the instillation of a drop or two of a solution of silver nitrate containing from 1 to 3 per cent. of the salt; and all head-coverings and napkins, shawls, and the like, to which discharge is likely to adhere and then dry up, should be frequently washed. By proceedings like these, Credé and the speakers at a recent meeting of the German Gynæcological Society were able to point to the satisfactory result that, from an average of 150 cases per 1000, the number of purulent ophthalmic cases in the German Lying-in Institution had fallen to 2, and even these were due to the fact that the appropriate measures were not properly carried out.

The streptococcus erysipelatos was first noticed by Lukomsky, who found it at the margin of an erysipelatous area where the disease was making active progress. The lymphatics of the skin presented the zooglœa of micrococci. The microbes in the centre of the area were dead. Orth and Fehleisen have experimented largely with the cultivated forms. It appears to present subordinate forms in different instances. Inoculation of the erysipelatous microbe into the ear of rabbits in *most* instances caused redness and increased heat of the ear, though both were less than when [illegible] was introduced. The

inflammation began in from thirty-six to forty-eight hours after inoculation in the form of a well-defined area of redness, which extended in the course of the veins to the root of the ear. The animals soon recovered completely. The difference between this microbe and that of ordinary pus, which it closely resembles in appearance, rests on experimental and clinical evidence. Streptococcus pyogenes occurs, according to Flügge, in about one half of all kinds of pus, while that of erysipelas occurs only in this affection, and it is, moreover, capable of being transmitted from one person to another. Fehleisen has continued the culture through seventeen or more generations on sterilised gelatine, and has still found that when inoculated into patients with a view of curing lupus, cancer, and sarcoma, a typical attack of erysipelas was induced.

The subject of acute infectious osteomyelitis was first worked at by Rosenbach, who thought the infection might be analogous to one of the ordinary ferments, and from experiment he arrived at the conclusion that it was the lactic acid ferment; but Kraske has quite recently demonstrated that several microbes are present in this disease, and that in all probability the active agent is the well-known form of micrococcus named M. pyogenes aureus, the co-operating agents being the M. pyogenes albus, the streptococcus pyogenes, and some forms of bacillus. The paths by which the poison may enter the system are various, and Kraske reports a fatal case in which the disease started from a furuncle on the lip. Similar results have been obtained by Becker.

Bacilli.—From the micrococci exemplified in these forms of suppuration let us turn to the other grand division of microbes, the bacilli. A typical example of the bacillus is presented by charbon, which has been so fully worked out by Koch and Klein; no spores are formed by it in the animal body; it increases only by fission in that situation. This bacillus is one of the most interesting on three grounds: first, that it was the first instance in which a microbe could be shown to induce disease; secondly, because it can attack man as well as animals, though certain breeds show themselves to be exempt from its attacks; and lastly, because by inoculation its virulent effects can be greatly modified. The charbon bacillus belongs to the aerobia, since its growth is almost arrested when the access of oxygen is cut off. The colonies when nourished on gelatine form small punctiform masses with wavy contour, which quickly spread over the surface of the gelatine, effecting partial fluidification. A mere trace inserted into the veins of mice, rabbits, guinea-pigs, hedgehogs, sparrows, sheep, or horses, causes sickness, which in the mouse may kill in twenty hours, and in rabbits in forty-two hours, the bacilli being found after death in the spleen and in the capillaries of the lungs, liver, kidneys, and intestines. Pasteur and Toussaint made the extremely important discovery that the exposure to moderately high temperature materially diminished the virulence of charbon bacillus, and that its action was also softened by certain poisonous substances, though their morphological features remained unchanged.

Bacillus of Syphilis.—The presence of peculiar forms of cells in syphilis had been announced by Hallier, Lostorfer, and others some years ago, before precise methods of investigation had been devised; but it was only in the course of last year that Lustgarten obtained by special modes of staining evidence of the presence of a microbe peculiar to syphilis. His plan was to make sections and place them in aniline water and a concentrated alcoholic solution of gentian; to remove the dye in a solution of potassium permanganate; the brown flocculi of reduced manganese dioxide were dissolved in sulphuric acid, and the sections then appeared completely colourless, with the exception of the bacilli of syphilis. Lepra and tubercle bacilli were stained in the same way. The bacilli found in syphilitic neoplastic formations resemble those of tubercle, and are usually curved, sometimes in opposite directions, and are on the average 4·5μ long, extremes being met with varying from 3 to 7μ. They often present a feebly marked enlargement at one extremity. The contours are not always parallel, but have kinks and indentations in their course. With high powers the bacilli appear of a deep-blue tint, and have bright oval spots arranged at equal distances from one another in their interior, which he thinks may possibly be regarded as spores. The bacilli are contained in large oval or polygonal cells, where [illegible] of from two to eight [illegible] intercross [illegible] the bacilli are rare, so that several sections may be made before a single bacillus, containing cell can be found. In examinations of sixteen cases Lustgarten found these cells to be invariably present, and in particular he found them in a periosteal gumma in a case of congenital syphilis. On the other hand, he was unable to find them in two excised soft chancres and in numerous pathological as well as healthy tissues which were examined after similar treatment; and the same difficulty has been experienced by other observers, and especially by Alvarez, who believes he has found the syphilitic bacilli of Lustgarten, or organisms indistinguishable from them, in the smegma of the prepuce or of the vulva.

Strümpell has quite recently called attention to the etiological relations that exist between tabes and progressive paralysis and syphilis. He found that in 61 per cent. of the cases of tabes that had fallen under his own observation syphilis had previously certainly existed, and that in no less than 90 per cent. it had probably been present. He endeavours to show by citing the analogous nerve degenerations that occur in diphtheria that we have not here to deal with the deposit of the primary disease-producing microbe in the nervous system and its multiplication there, but rather that the secondary disease proceeds from some chemical poison produced no doubt by the original microbes. Similar nerve conditions occur after typhus and after dysentery. The most severe forms of nervous affection may follow the simplest and slightest attacks of these diseases. The attack of tabes so long after that of the original syphilis is not surprising when we reflect how chronic a disease syphilis is. It must be acknowledged, however, that the view that the secondary affections of syphilis are due to the secretion of syphilis bacilli—that is to say, to ptomaines produced by them—is far less probable than that the bacilli wander from the original seat of inoculation and induce local disease. Take, for example, syphilitic iritis. Surely the blood poisoning which would excite a sharp attack of iritis would produce serious disturbance of many other organs; but we can easily explain the occurrence of the iritis if we admit that the bacilli are carried by the current of the blood till they are arrested in some spot which, like the highly vascular iris, is well fitted for their multiplication; and it is not, then, surprising that there may be no other signs of constitutional disturbance than such as are occasioned by the local conditions of pain.

Another subject of the highest possible interest to the surgeon—the etiology of tetanus—has recently received some elucidation from the labours of Roser and Heiberg, of Rosenbach, of Göttingen, and of others. The causes of this affection have hitherto been in the last degree obscure, and I need hardly do more than refer to the reflex irritation theory. Roser and Heiberg first suggested that, owing to the formation of some miasm, a poison was generated which, being absorbed, caused the disease. Though supported by many observers, as Arloing and Tripier, Billroth and others endeavoured to transmit tetanus by inoculation, and failed. In fact, these negative results appear to be attributable to the circumstance that dogs were chiefly used for experiment, animals that appear to be singularly indisposed to suffer from tetanus. The first positive results were obtained by Carle and Rattone, who obtained from a pustule of acne matter which, being injected into twelve rabbits, caused eleven to be infected with tetanus; and further, the disease was transmitted from one of these animals to another. More recent observations have been made by Rosenbach, who took the material for his experiments from the body of a workman aged twenty-three, who in February of the present year had frost-bitten feet, and who died the day after his admission into hospital from tetanus. It was taken an hour after death from just below the line of demarcation. Two guinea-pigs into whose thighs small fragments were introduced in the evening exhibited well-marked tetanus the following morning, and died in the course of the day. The inoculation of other animals from these only succeeded when the material used for inoculation was taken from the immediate vicinity of the point inoculated. But when this was done, four guinea-pigs and eleven mice were rendered tetanic. The tetanus thus produced was in all respects identical with Nicolaier's earth-tetanus. It differs in the order of the appearance of the symptoms according to the position of the place where the inoculation is made. For example, if in a mouse the inoculation is made in the groin, the tail is found, after incubation of from nine to twelve hours, to be erect and

directed stiffly to the side inoculated. The corresponding leg is stiff in all its movements, and is soon stiffly extended, the sole turned upwards, the toes clenched. The same phenomena are then seen in the opposite posterior extremity. The stiffness extends to the lower muscles of the back. The animal can only move by means of its fore feet. After the lapse of eighteen hours the anterior extremities become stiff, and immediately after trismus and opisthotonos, and with every touch, even mere contact of the glass jar, tetanic spasms set in. The animal then lies in a state of exhaustion, with intense dyspnœa, and soon only slight shallow respiratory movements and feeble convulsions afford evidence that life still persists. Death usually takes place in twenty-four hours. If a mouse were inoculated at some other point—as, for example, over the humerus—the extremity soon became motionless, and quickly became prone and stiff; a few hours later the ear fell back, the prominent eyeball of the field mouse became retracted, the lids half closed, the jaws tightly closed; eighteen hours after the inoculation the whole body was bent towards the inoculated side, the left fore foot stiff, the hind foot movable; on contact tetanic cramps were excited, and again in twenty-four hours the animal was dead. The process was the same in guinea-pigs and in rabbits, though in the latter animals the general tetanic convulsions were less marked. The period of incubation is at least twenty-four, and in the majority of cases thirty-six, hours. Professor Flügge and his coadjutors informed Rosenbach that they had been able to obtain pure cultures of earth-tetanus-bacillus, but that they experienced great difficulty in transferring such pure cultures from one medium to another. Experiments made with a view of explaining this peculiarity suggested that the presence of some other fungus was requisite; in other words that, as occurs in some of the higher animals, commensalism existed, perhaps due to the fact that the companion fungus promoted its growth by absorption of oxygen; and this observation, if supported by others, is interesting in connexion with the fact that tetanus is peculiarly liable to follow wounds in injuries in which foreign bodies or necrosis and gangrene are present. The question whether the tetanus bacillus spread itself throughout the body, and by what channels this occurred, has been the subject of many researches by Nicolaier, who found the bacilli in question once in the sciatic and twice in the spinal cord. Inoculation with fragments of organs succeeded fourteen times in fifty-two experiments. As the bacillus does not appear to be very abundant, it is difficult to understand how the simple growth of a fungus could produce such violent effects upon the nervous system, and it seems more probable that, as the old supporters of the zymotic nature of tetanus thought, some kind of poison resembling strychnia is generated by the bacilli. We may suppose, then, that the bacilli streaming forth from the point of inoculation as from a centre distribute themselves through the body, and, further, that each bacillus lying in tissues represents a small but constantly acting source of poison, which first affects its own immediate vicinity, but as a consequence of absorption and in co-operation with others, affects ultimately the whole body, and we may thus explain the local tone and tension, its gradual extension, and finally the affection of the whole system.

It is interesting to consider how these organisms exert their baneful influence on the living bodies of the higher animals. How, for example, does the bacilli of splenic fever act upon cattle? There are clearly four ways in which we may explain the action of microbes upon the infected animal. In the first place, they may act like an invading army on a peaceful population; they may simply consume their stores of pabulum. Possessing greater strength and vitality than the normal tissues, which are highly specialised and perhaps require more complex food—that is, food which has been more or less highly assimilated,—these young and vigorous warriors seize upon and appropriate the raw material, and practically starve out the more delicately framed cells. And this action cannot be overlooked, in whatever mode we may seek to explain their influence. Their enormous rate of reproduction has been already referred to, and we have only to look at the drawings of Klein and others of the thorough infiltration of many organs to understand what a powerful influence they must exert in this direction, and how the normal cells weakened by inanition may fall, like Gulliver before the Liliputians, victims to the attacks of their minute but numerous and persevering enemies; and if any further proof were needed, it would be found in the serious effects that are produced upon the economy by any constant drain, whether it be from an imperfectly healed abscess, from leucorrhœa or even from purulent ophthalmia. Secondly, they may act by interfering with the due performance of the functions of the various depurating organs. Klein, in his numerous and excellent drawings, has frequently represented the kidney, and we see the capillaries of the glomeruli blocked up with myriads of microbes. It is clear that the urea and other final products of the regressive metamorphosis of the tissues must be imperfectly eliminated, and if retained in the body must contribute their share in the development of disease.

But another view may be held. It may be said, so far as we know, all living beings produce excreta, the simplest of which, carbonic acid and water, contain the carbon hydrogen and oxygen of the food; whilst the nitrogen is eliminated in the form of urea or uric acid or guanin, or some other soluble and generally poisonous compound. Microbes can constitute no exception to this rule, but whereas in most instances the products of excretion are thrown forth into the vast receptacles of the atmosphere or of the waters, or of the soil of the earth, and by the play of other forces become harmless, they are here discharged into the body of the animal on which they are living, and so bring about its destruction more or less quickly, but as surely as if that animal's own excreta were retained in its body.

There is still another explanation which on many grounds has recommended itself, as accounting more satisfactorily for the phenomena observed, both to chemists and biologists. It is that the injurious effects produced by microbes is due, not to what they take or to what they excrete, but to what they leave, and this is closely associated with the imperious demand they make for oxygen. Being in many instances anærobic—that is, living and multiplying without direct exposure to air,—they must obtain the oxygen they require for the process of life from the tissues by which they are surrounded; but when oxygen is withdrawn from such complex chemical compounds as those of which our bodies are constructed, the elements enter into new combinations, and then, under the name of ptomanies (from πτῶμα, a dead body), are believed to be the really poisonous agents. Attempts have been made to isolate these compounds; and it has been shown that they are of the nature of alkaloids, and resemble, both in their constitution and in their effects, those deadly poisons that may be extracted from digitalis, conium, tobacco, delphinum, and other noxious plants. In reference to this it may just be noted that Miquel has cultivated a bacterium which has the singular power of converting a gramme of sulphur in the course of forty-eight hours into hydro-sulphuric acid on the addition of four litres of boiling water and some tartrate of ammonium. This bacterium often fixes itself in vulcanised indiarubber tubes, and in the course of a few hours can charge the water they contain with from 60 cc. to 70 cc. per litre of sulphuretted hydrogen.

The difficulty which must strike everyone in regard to the action of these microbes on the body is the comparative rarity of disease. How is it, if the air is swarming with these ferocious microbes, that we do not all succumb to their attacks? How can anyone escape? Pasteur meets the difficulty by stating that the healthy body is capable of resisting the attacks of these foreign agents, and that so long as the surface is intact no harm comes from their ingestion. A healthy man is probably capable of resisting the attacks of the majority of pathogenic organisms, at least for a time. The cells which cover the surface of our bodies and line our alimentary respirators and genito-urinary tracts possess their own vital energy, and when perfectly normal cannot be invaded by any microbe; they present an impenetrable front to such organisms along their whole line. When, however, by mechanical, chemical, or other injury the vitality of these cells is lowered, a door is opened for the admission of such organisms, which, having once penetrated the tissues or the blood, find a fit soil for multiplication; and these may prove, by their mere numbers or by their effects, injurious or fatal to the whole body. Nothing can demonstrate this better than the experiment recently made by Orth and Wyssokowitsch, who found that staphylococcus could be injected into the blood of a rabbit without apparent injury to it; but if before the injection a slight mechanical injury was inflicted on the valves of the heart, typical endocarditis was at once produced.

I point out that this branch

of inquiry is of quite a special character, and that it requires very considerable practice and entire devotion of time. Take my own case. I was most desirous to obtain cultures from various diseases of the eye attended with suppuration to illustrate this lecture, but it is requisite in the first instance to have sterilised tubes and plates to grow the microbe. Though pretty well accustomed to delicate operations, very special precaution is required to introduce the matter gained without entrance of foreign bodies. Then an incubator is wanted; and finally there is the long and difficult examination with the microscope, with all its details of cutting, staining, mounting, and, not least, preserving in an accessible form. On these grounds I hope that the Council of the College will see fit to institute with part of Sir Erasmus Wilson's bequest a laboratory devoted to this object, where one or two able demonstrators may continue the study of bacteriology, and prosecute, with all modern appliances, those researches, which are certain to prove of service in the diagnosis and treatment of disease.

A Clinical Lecture

ON THE

PATHOLOGY AND TREATMENT OF CHRONIC CONSTIPATION IN CHILDHOOD, AND ITS SEQUEL, ATONY AND DILATATION OF THE COLON.

Delivered at the Hospital for Sick Children, Great Ormond-street,

BY W. B. CHEADLE, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE HOSPITAL; PHYSICIAN AND JOINT LECTURER ON MEDICINE, ST. MARY'S HOSPITAL.

(*Concluded from page 1064.*)

IN the case last mentioned the nausea and headache were frequent, coming on at irregular intervals without any great coating of the tongue or sign of special bilious disorder. In other instances, however, the attacks are periodic, coming on once in every three, four, or six weeks with considerable regularity, and accompanied by great coating of the tongue with vomiting and considerable fever. The constipation is habitual and persistent, but it would seem as if the fæcal poisoning were cumulative. In the intervals between the attacks the patient remains fairly well; then the child grows feverish, the tongue becomes greatly coated, headache and vomiting supervene—in fact, culminate in an attack of migraine, not cured or alleviated by bromide of potassium or other sedatives or neurotic remedies unless accompanied by a purge, but removed at once by a dose of calomel or other purge, to recur again after three or four weeks' respite. Such cases are, however, curable by the steady administration of laxatives with strychnia or nux vomica, with bromide of potassium in addition in some cases, and regulation of diet. Of this form the case I now relate affords a good example.

CASE 5.—W. W——, aged three years and a half, a fairly healthy-looking, fairly nourished boy, was brought to me in March, 1882, for attacks of headache and vomiting. The attacks came on every three or four weeks; the first sign being some feverishness, coating of the tongue, and loss of appetite. In the course of a day the tongue became more coated still, the breath offensive, the headache severe, and vomiting usually followed; with rest and a good deal of opening medicine the attacks subsided. The bowels were extremely constipated. The boy always complained of a little headache, even in the intervals between the attacks. A dose of calomel (two grains and a half) was prescribed at once, and sulphates of magnesia and soda, with strychnia and iron, were given twice a day after food to keep the bowels open daily. The next attack was slight, although the bowels were still somewhat confined, and the laxative was increased.

This case was one of mixed [illegible] constipation, and relieved at once by its removal. In some cases no doubt this is not alone sufficient for cure, and patients are benefited by the addition of bromides and croton chloral. But when migraine is accompanied by constipation, as it is almost invariably in children, the cure of this is the most essential part of treatment, and rarely fails to stop the periodic headache and sickness. In other instances, again, the symptoms of headache and nausea are comparatively unimportant, but there is general loss of health, with more intractable constipation, considerable abdominal distension and flatus, and signs of considerable dilatation of the bowels, especially of the large intestine, the heart being in some cases considerably displaced upwards, and its action seriously interfered with. These cases are highly interesting and important, for the distension and dilatation of the gut are largely due to mistaken treatment. The progressive atonic distension of the bowel is probably due in part to the pressure of fæcal accumulation and gaseous distension arising from fermentative decomposition, but in greater measure still to the loss of tone and peristaltic power consequent upon the constant stimulation by irritant purgative drugs; and more still by the undue expansion of the loaded intestinal tube by frequent injections. The following case illustrates this point.

CASE 6.—F. F——, aged six years, was brought to me in June, 1885, on account of distension of the abdomen and intermittent feverish attacks, with headache, nausea, and sometimes vomiting. The temperature was often as high as 101°; the tongue always coated, especially at the time of these febrile bilious attacks. The last three attacks had appeared with great regularly at intervals of six weeks. The bowels had always been constipated, and were now more so than ever, in spite of frequent doses of all kinds of aperient medicines, and latterly of the use of enemata. The abdomen had become more and more distended, so much so that the doctor in attendance advised the use of an elastic abdominal belt to support it, and this the boy had worn for some months. The enlargement of the abdomen was due to gaseous distension; there was no effusion. No scybalous masses could be detected, but some rounded bodies (either enlarged glands or small scybala) were indistinctly felt deep down towards the middle of the abdomen. A mixture of strychnine and iron, with three-quarter drachm doses of sulphates of soda and magnesia, were ordered twice a day after meals. In a week the boy was already much better. There was no return of the bilious attacks. The bowels acted daily. The abdomen began to go steadily down. The medicine after a time was gradually reduced. The bowels were kept open. Six months later the bandage was left off, the abdomen being normal in size and character. Not a single relapse occurred from the first. No more strong purgatives or enemata were used.

Here, again, is a case in which such simple measures as I have detailed were sufficient after the strong and vigorous means tried before had failed, and worse than failed—made matters steadily worse. The original cause of the constipation was not clear. It dated from early infancy, and probably had its origin in milk food insufficiently stimulating the intestine, aggravated by the dislike of the child to aid evacuation, and his desire to resist it since it had become painful. Later, stimulating purges and enemata had increased the evil.

Here is a similar but still more striking case:

CASE 7.—C. M——, a fairly healthy boy, aged three, was brought to me in February last on account of a large tumid abdomen and obstinate constipation, which had existed since he was three months old. The motions were dry, whitish, and hard. The child's general health was impaired; he had little appetite, was languid, but had no headache or nausea. Every purgative known appeared to have been given. Here is a list the mother gave me: castor oil, grey powder, calomel, senna, scammony, jalap, podophyllin, Steedman's powders innumerable, Gregory's powder, belladonna, rhubarb, and cascara sagrada.[1] But all these had failed in turn, and latterly for the last two years, indeed—enemata had been given constantly, not infrequently two in a day. If the first was retained a second was given. Once or twice three had been given in the day, the first two being retained; so that oftentimes the gut was distended with two or three together. The bowels never acted without injections, except for a short time at Brighton in the spring. Sometimes three enemata were retained, and did not act until the following day. On

[1] The list is not exhaustive; but these are just what the mother could call to mind at the moment.

examining the abdomen, it was seen to be greatly distended, especially immediately under and below the false ribs, from the epigastrium to the umbilicus. This characteristic feature indicated the colon to be greatly expanded. Here it was more tense than below the umbilicus, where the abdomen was softer. The heart's apex beat was exactly at the nipple, and on percussion the tympanitic bowel note was found to extend upwards to a finger's breadth below the nipple. The girth at the largest point above the umbilicus was 23½ in.

Here the distension was clearly due to dilatation of the colon, evidenced by the position of greatest distension at the epigastric line, the pushing up of the heart, and the tympanitic resonance extending upwards to the nipple line. This persistent dilatation had been brought about, as in the last case, partly by the accumulating fæces and gases of constipation, but especially by the constant forcible distension of the gut, already loaded with fæces, by the enemata. The fact that two or three ordinary enemata were retained sometimes for twenty-four hours spoke volumes for the capacity of the large bowel. Under similar treatment by sulphates, strychnia, and belladonna, with appropriate diet—i.e., diet of a simple kind, with fruits (but no coarse food, like oatmeal),—the wearied, enfeebled intestinal walls began to regain tone and power, and the increased fluidity of the stools enabled slight peristalsis to act effectively. In the course of two months' steady treatment of this kind the distension subsided, and the child is now nearly well, the bowels acting daily and the abdomen being almost normal in size, so much so that the bandage has been left off.

Lastly, let me give a case of like character, but more extreme and protracted, and still under treatment from time to time. It is now nearly two years since its first commencement.

CASE 8.—Arthur H---, a delicate boy of the age of five years and a half, was sent to me by a medical man in June, 1884, on account of obstinate constipation, which had existed for nine months, and had resisted all treatment. The usual vicious plan of giving stronger and stronger aperients frequently had been adopted, and latterly, when these had ceased to be effectual, enemata. This had now become the regular practice; the bowels could not be opened without injections. Sometimes these were retained, and had to be repeated two or three times. The boy dreaded the action of the bowels, and resisted it with all his might. The abdomen was much distended, especially the portion answering to the position of the transverse colon; and there was great tympanites. The first cause of the constipation was obscure; probably some slight derangement and neglect. This had been developed by mistaken treatment into confirmed constipation from atony of the intestine and dilatation. Half-drachm doses of sulphate of magnesia, and the same quantity of sulphate of soda, with iron, strychnine, and belladonna, soon gave daily action, and this at last increased to diarrhœa, when the medicine was reduced and then omitted. The child was well at the end of three months. He remained well for nearly four months, the bowels acting regularly without medicine; then the bowels again became constipated, owing, it was supposed, to a severe cold. The laxative medicine was resumed, but it produced no effect and caused griping pain. A doctor was called in, who at once unfortunately ordered regular injections, and the constipation went on increasing, the abdomen becoming again distended. The boy was then brought to me in the same straits as before, and he was admitted into this hospital. A pill of calomel and colocynth, followed by a small castor-oil enema, unlocked the block. The boy caught scarlatina, but he did well, and the saline laxatives, with strychnine, were then resumed, and the child again recovered as before. He went out in March of last year. After that the bowels acted regularly for four months; then diarrhœa set in after an attack of some eruptive fever—probably measles. Then constipation recurred, with much griping pain, which, occurring very frequently, prevented sleep, due clearly to ineffectual peristalsis. The doctor was called in at home, and gave again repeated injections, with little or no effect. Ultimately the boy was once more brought to the hospital, and readmitted last December. The abdomen at this time was found to be greatly distended, especially above the umbilicus, by an enormously dilated colon; excessive drum-like resonance reached as high as the nipple-line. The abdomen measured 21¼ in. at the largest circumference over the false ribs. The heart's beat was seen in the first, second, and third spaces; the apex at the nipple. He was suffering from constant colic, with loud rumbling noises. The bowels did not act except by repeated enemata given several days together. A bandage was applied firmly to the upper abdomen, which was rubbed and kneaded daily with cod-liver oil. To relieve pain a mixture containing two minims each of tincture of opium and of tincture of belladonna, with cardamoms and ginger, were given, and the bowels emptied by small castor-oil and olive-oil enemata. The plan did not answer; the pains continued, and the abdomen became enormously distended, measuring 22½ in. The boy grew pale, and lost flesh; appetite entirely failed; vomiting occurred; the circulation became extremely feeble from the pressure on the heart; the face and lips and fingers assumed a blue tint. There was extreme debility and tendency to faintness. The patient became worse daily; râles began to appear in the lungs. In view of the collapsed state of the child under the upward pressure of the colon, it was decided to puncture it with a fine trocar, which was accordingly done with a thoroughly carbolised large hypodermic needle in two places between the ensiform cartilage and the umbilicus. Gas issued freely through the needle; a large quantity was allowed to escape. The distension subsided, and immense relief followed. The old mixture of belladonna and strychnia, with the sulphates of soda and magnesia, were resumed. The abdomen steadily decreased in size. The bowels began to act freely. Arsenic and iron were given in addition, and in six weeks' time the boy again went out well. The heart's position, however, was unchanged. He was bandaged, and the medicine continued in smaller doses. I had enjoined this patient to come in again last week, in order that you might have the opportunity of examining him, and also for the purpose of being galvanised with the view of causing contraction of the still greatly dilated colon. Unfortunately he developed scarlatina, and is now in the isolation ward with a second attack.

This specimen of dilated colon from the museum which I show you is from a case of atresia ani, the enormous distension being the result of pressure by cumulation and gases, with ineffectual peristalsis, similar to that produced by analogous mechanical causes in some of the preceding cases. The colon appeared to fill almost the whole abdominal cavity when it was first opened at the post-mortem examination. This distension of the colon in children appears to have been unnoticed, although Henoch speaks of cases in which constipation leads to extreme distension of the abdomen, with pain and tenderness, so as to simulate peritonitis. The swelling of the abdomen is put down to chronic peritonitis or to tabes mesenterica. These cases are seen chiefly amongst the children of the better class of people. They are not so common amongst hospital patients. The reason is, I imagine, that the poorer children are less treated.

Gentlemen, my object in these lectures is not so much to describe the cause and symptoms of constipation as to point out the disastrous results of mistaken treatment, and to enforce the necessity of a more rational procedure. Look at the evil effect of strong purgations—how they enervate and wear out the tone of the bowel. No occasional purge of rhubarb or scammony is efficient to cure. Look, again, at the evil effect of frequent enemata. Enemata are only to be used on an emergency. They, equally with strong purges, impair tone and do direct harm by actual dilatation. In confirmed cases of constipated habit, treatment must be not intermittent, but continuous; the daily administration of appropriate remedies steadily, for a considerable period, is absolutely essential. Intermittent treatment is abortive, ineffectual, and aggravates the evil. What, then, is the proper treatment for these cases? First, be sure that there is no malformation, no intussusception, no sore about the anus, rendering defecation painful. Then use saline laxatives. Their mode of action is by increasing the flow of secretion rather than by stimulating peristalsis. Thus tone returns when distension is relieved by the easy evacuation of fluid stools. Further aids to this are strychnia, nux vomica, iron, and belladonna. They act by increasing muscular tone and nutrition, not by stimulating peristalsis directly. In the case of little children up to two years old simple carbonate of magnesia in milk is sufficient (5 to 10 or 20 gr.); this is better than the piece of soap in the rectum, or the repeated castor oil or manna so constantly advised. In older children, the sulphates of magnesia and soda, with the tonics named above, and daily massage with castor oil or cod-liver-oil, are most useful. In older children still, a pill of aloes or euonymin, with sulphate of iron and nux vomica, may be given as an alternative to the salts and strychnia, but no frequent use of [redacted]mmony, or podophyllin, or

jalap (these are for the relief of temporary difficulty only); in mild cases, perhaps, or if the liver is not acting, a dose of calomel, grey powder, and soda, or senna. Regimen is an important element in the treatment if the child should have chronic constipation: abundant water, pure, not hard; "salutaris water" is excellent. In little children add a good infants' food to milk; fruits; fruit jellies; treacle; cooked green vegetables of the softer and more delicate kinds. Some variety in food is useful; a good mixture is better than a monotonous diet. It is, I think, extremely doubtful if coarse food is useful in the long run. It causes atony and weariness of muscle eventually by over-stimulation. And you must insist on regular evacuations. Take care that the stools are not dry and hard, or the child will resist action and increase constipation. Other useful adjuncts are—abundance of fresh air, which aids in improving nutrition; and exercise, which mechanically aids the passage of the contents of the intestine down the tube, and improves general health and muscular tone.

SOME OBSERVATIONS ON RUPTURE OF THE URINARY BLADDER,

WITH AN ACCOUNT OF TWO CASES OF INTRA-PERITONEAL RUPTURE SUCCESSFULLY TREATED BY ABDOMINAL SECTION AND SUBSEQUENT SUTURE OF THE VESICAL RENT.

BY SIR WILLIAM MAC CORMAC,

SURGEON AND LECTURER ON SURGERY, ST. THOMAS'S HOSPITAL.

Two cases of intra-peritoneal rupture of the bladder have been recently under my care in St. Thomas's Hospital. In each case abdominal section was performed very shortly after admission, the rent in the bladder exposed, and carefully closed by numerous interrupted silk sutures. The cavity of the peritoneum was then thoroughly washed out with warm boric solution and the external wound closed. An uninterrupted recovery followed in both instances, the first, so far as I can learn, upon record.

The injury is comparatively very rare. During ten years only five cases of rupture of the bladder, not including the two now recorded, were admitted to St. Thomas's Hospital. In France, Germany, and Austria I learn that this form of injury is extremely rare. Intra-peritoneal rupture of the bladder has hitherto proved almost uniformly fatal. Sir Henry Thompson, in Holmes' System of Surgery, last edition, says "recovery can hardly be regarded as possible." Some few cases of alleged recovery have been recorded, but in all but perhaps one of these, where the abdominal cavity was opened, the diagnosis must be considered as more or less doubtful. In the case above adverted to, Walter of Pittsburg, U.S.A., performed abdominal section ten hours after the patient had received a blow on the lower abdomen. A pint of blood was sponged out of the peritoneal cavity, and a rent two inches long seen in the bladder. This was not further interfered with. The abdominal wound being immediately closed, opium was given and a catheter introduced into the bladder. Recovery ensued.

The most recently published article on the subject is by Mr. Rivington, in "Heath's Surgical Dictionary" (1886). He there states that "no indubitable case of recovery after intra-peritoneal rupture of the bladder is on record." Unfortunately, the experience of operative interference has been equally unsatisfactory. In a very few cases abdominal section has been performed with subsequent suture of the intra-peritoneal rent, but hitherto without success, unless Hofmokl's case be so regarded. Mr. Heath,[1] Mr. Willett,[2] and Mr. McGill of Leeds[3] have published cases of intra-peritoneal cystoraphy these being, so far as I know, the only ones in this country. Professor Hofmokl,[4] relates a case of rupture of the bladder complicated with separation of the symphysis pubis. The subject fell from a height to the ground and fractured the pelvis. The symptoms were chiefly those of extra-peritoneal rupture. On an abdominal incision being made much blood and urine were found in the cellular tissue behind the pubes, and the bladder was torn opposite this, the serous layer being detached for a little distance over the fundus. Although some bloody fluid was found in the peritoneal cavity, the description does not make it clear that the rent in the bladder extended through its peritoneal investment. The rent was partially sutured and the patient eventually recovered. In the cases of Messrs. Heath and Willett the sutures gave way near the lower angle of the wound, and fresh extravasation took place. They were passed through the whole thickness of the bladder, which Maximow,[5] in his experiments on dogs proves, was always attended by fatal consequences. Mr. J. Duncan of the Royal Infirmary, Edinburgh,[6] has also performed abdominal section in one case, after failing to find the rent by digital exploration after perineal cystotomy; and, just as in the instance of Walter of Pittsburg, he did not suture the rent in the bladder. A fatal result followed, apparently due to suppression of urine. Mr. Brown, of the Leeds Infirmary,[7] performed perineal cystotomy with subsequent drainage. The rupture, although sufficiently large to admit the end of the middle finger, was not discovered by the finger passed into the bladder. The patient did not rally from the operation, and shortly after died. Extensive recent peritonitis was found post mortem. There was no history of injury in this case. Mr. McGill, of the same hospital,[8] records a case of intra-peritoneal rupture by direct violence. He sutured a median vertical rent in the bladder, four inches long, with nine chromic gut sutures. The operation was performed about sixty-eight hours after the accident. The introduction of the sutures was found to be facilitated by the previous distension of the rectum with an air tampon, which materially raised the recto-vesical culde-sac, a method suggested by Gueterbock.[9] The patient, who was fifty-four years old, sank the following day from shock. At the necropsy, performed three days and a half after the accident, there was no fluid in the peritoneum. No signs of peritonitis were found, and nothing very abnormal in any organ. Mr. Teale some years ago stitched up a ruptured bladder and inserted a drainage-tube through the perineum. The patient died the same night, his death being apparently accelerated by considerable hæmorrhage from the perineal incision.

There is thus considerable diversity in the practice recommended for adoption in cases of intra-peritoneal rupture of the bladder. Catheterism simply has been practised, or washing out the peritoneal cavity from the side of the perineum or urethra; median or lateral cystotomy has been performed to provide direct drainage through the perineum; aspirating the abdominal cavity, abdominal section, sponging out urine and blood from the interior, leaving the rent undisturbed, have been adopted in at least two instances; and lastly, abdominal section, with suturing of the rent in the bladder, in some cases completely, in others leaving the anterior part unclosed, or making a drainage opening in the part of the bladder uncovered by peritoneum, has been tried.

CASE 1. (Mr. Cooper and Mr. Brockway, dressers; Mr. F. Nichol, house-surgeon).—William S——, aged thirty-three, labourer, an old soldier, was admitted into hospital on Sept. 22nd, 1885. About 8.30 P.M. on the 21st, the patient, whilst pursuing his son, ran "full tilt" against an iron upright post at the entrance to a court. The head of the post struck him in the region of the umbilicus; he fell to the ground, and for a minute or two felt stunned, but soon was able to rise and walk slowly home in great pain, a distance of 250 yards. He vomited twice shortly after the accident, and about half an hour later felt an inclination to micturate. He tried and failed, but a strong desire continued. Throughout the night the abdominal pain was severe; he walked up and down his room, unable to remain at rest or lie in bed, and striving continually to pass urine without success. He had micturated, he felt sure, an hour and a half before the accident. He had drunk about a quart of beer during the evening, but denies that he was intoxicated. In the morning, the pain increasing and finding himself unable to pass urine, the man walked, unaided, to the hospital about noon on the following day, a distance of one mile. There does not seem at any period to have been anything like collapse.

On admission, fifteen hours and a half after the accident, the patient, a powerfully built, healthy-looking man, of florid complexion, complained of intense abdominal pain

and betrayed the anguish he suffered in his face. The inability to pass urine was complete; his expression was very anxious, and his manner uneasy. There were then no symptoms of shock. The abdomen was distended and exceedingly tender all over, more especially in the epigastric and hypogastric regions. There was resonance anteriorly, with dulness in both flanks, varying in extent with the position of the patient. A No. 6 soft black catheter was passed, and one ounce and a half of urine, slightly tinged with blood, drawn off. Temperature 99·8°; respiration 24. About 2.30 P.M. I saw the patient, and on again introducing a catheter drew off ninety-five ounces of slightly red coloured fluid. The point of the instrument seemed grasped, and did not move freely, proving the bladder to be contracted, but the existence of any damage to its wall could not be made out. The level of dulness in the flanks was sensibly diminished, and the patient experienced some relief. Taking into account the history, symptoms, and especially the large amount of blood-stained fluid removed, an intra-peritoneal rupture of the bladder seemed probable, and I decided that abdominal section should be performed at once, it being then some nineteen hours after the receipt of the injury.

Operation.—At 3.15 P.M., the patient having been placed under the influence of ether, a full-sized catheter was introduced and four or five ounces of bloody fluid drawn off. An incision about six inches in length was made in the median line terminating just over the pubes. The abdominal wall was very fat. The linea alba having been divided and the recti muscles retracted, all bleeding points were secured before the peritoneal cavity was opened. On fully dividing the peritoneum and retracting the margins of the wound, an extensive rent could be felt in the bladder, and the point of a catheter could be perceived free in the peritoneal cavity. The bladder was empty and firmly contracted behind the pubes. No urinary smell was perceptible. The rent was in the posterior aspect of the bladder, and extended from the superior fundus to the recto-vesical cul-de-sac; it was median and vertical, and as nearly as may be four inches in length. The edges were rather irregular and thickened. So deeply did the rupture extend into the pelvis that great difficulty was afterwards experienced in the introduction of the deeper sutures. To facilitate this the parietal peritoneum was divided transversely on each side, and it was then found possible to draw the bladder much further out. The intestines were pushed back with sponges held by one assistant, while a second pulled the bladder forward. Sixteen sutures of fine silk were then introduced after Lembert's method, including the serous and muscular coats only, at intervals of about a quarter of an inch apart, beginning at the lower part, and the first and last sutures were introduced quite beyond the limits of the injury. The edges of the mucous membrane were thus thoroughly inverted and the serous surfaces brought into contact (Fig. 1). Wherever the closure did not seem absolutely complete and perfect, catgut sutures were introduced to the number of six or eight between the silk ones, including the peritoneum only. The bladder was now twice moderately distended with a weak solution of boric acid injected through the catheter by a Higginson's syringe, and proved perfectly watertight. The peritoneal cavity was finally irrigated with two gallons of a 1 per cent. solution of boric acid dissolved in water previously boiled and cooled down to a temperature of 98° F. The fluid was introduced by means of a tube attached to an irrigating can raised 8 ft. from the floor. It overflowed into a macintosh and thence to a tub placed at the foot of the table, in the manner customary during ovariotomy. The irrigation was continued until the escaping fluid became absolutely clear. There was no sponging of the peritoneum. A glass drainage-tube was introduced from the centre of the wound to the recto-vesical cul-de-sac. The edges of the peritoneum and external wound were then closed by deep silk sutures, and iodoform, iodoform gauze, and salicylic wool applied, with bandages of carbolic gauze. A soft black catheter was fastened in the urethra, the tip only projecting into the bladder. The operation lasted two hours, and was conducted under the carbolic spray throughout, save for a few minutes when the steam failed. The peritoneum and intestines looked quite healthy, presenting a polished appearance, apparently not injected. No blood-clots were observed.

The subsequent progress of the patient may be briefly summed up. Almost directly after the operation all pain and abdominal tenderness completely disappeared. There was no sickness. The man slept quietly through the night, an injection of a quarter of a grain of morphia being given. During the subsequent five days the temperature never reached 100°; on the eighth and ninth days it was a little over 100° in the evening. The pulse and respiration were normal. He passed from thirty to forty ounces of urine daily, at no time containing any blood. This was at first drawn off by the catheter at intervals of four hours; but on the third day the catheter was removed, and subsequently he passed urine naturally, the instrument not being again needed. As regards the abdominal wound, it healed quickly and well. A very small amount of serous discharge was sucked out of the drainage-tube at each dressing, and on the fourth day the drain was removed altogether. The opening it left somewhat delayed the final closure of the wound, but on the eighth day the sutures were removed, and within the fortnight the abdominal incision had cicatrised and the patient pronounced convalescent. In three weeks the man was able to rise, and he shortly after went home and resumed his ordinary work, as well apparently in all respects as he was before the accident. Beyond what was incident to confinement in bed there was no discomfort complained of, and he had not a particle of pain or distress of any kind throughout. None of the sutures were seen in the urine while the man remained in hospital, though carefully looked for.

CASE 2. (Mr. F. Nichol, house-surgeon; Mr. C. H. James, dresser, to whom I am indebted for these notes.)—C. F——, aged thirty-seven, a slater, living at Camberwell, was admitted on Nov. 17th, 1886. The subject of the accident is a stout, heavy-built man, 5 ft. 6 in. high, weighing 15st. On the day previously, at 11.45 A.M., while he was at work on some scaffolding, he stepped backwards and fell a distance of eighteen or twenty feet, in a sitting posture, upon some soft clay. He did not become faint, or indeed have any symptoms of collapse, nor did he consider himself seriously hurt. He was able to walk a few yards to a cab. While waiting for this to come up he had a desire to pass urine, but failed to do so, and the desire soon left him. On arriving at the hospital at 1 o'clock, he walked in, getting the porters to assist him on account of his back feeling so "queer." It was then found that the skin in the region of the sacrum was bruised and slightly ecchymosed. No injury to the pelvis or spinal column was detectable. In the casualty room he was able to stand and move about without apparent inconvenience, and complained of no abdominal pain or tenderness. He had no particular pain or distress of any kind. He stated distinctly that he had no desire to micturate, and therefore a catheter was not passed. He had drunk one pint of beer about half an hour before the accident, and had micturated about the same time. He had also had a pint of beer between 6 and 7 A.M. A flannel bandage was applied to the abdomen and hips, and he was told to return home and rest quietly. About 4 o'clock the same afternoon he commenced to feel a little pain at the lower part of the abdomen, but it was so slight that it was not mentioned when his club doctor visited him at about 5 P.M. in order to give a sick certificate. In fact, he felt fairly well till about 6 P.M., when he experienced some pain and a desire to micturate, and again failed to pass anything. This desire became more and more urgent, and the fruitless efforts to gratify it kept him awake all night. There was no vomiting. At 9 A.M. on Wednesday his club doctor again visited him. Then he complained of great abdominal pain and tenderness, and a strong desire to micturate. The doctor tried to pass a catheter, but, failing to get it into the bladder, recommended the patient to go to the hospital without delay.

At 11.30 A.M. the patient was brought to the hospital in a cab, and admitted. He was seen by the house-surgeon, who tried to pass a full-sized catheter, but on account of a moderate stricture about four inches from the meatus was unable to do so. A No. 6 silver catheter was easily passed, and six ounces of turbid coffee-coloured urine were drawn off. The abdomen was extremely tender all over, especially in the epigastric and hypogastric regions. It was not much distended or very tense. It was resonant all over anteriorly, but dull on percussion in the extreme flanks, the dulness shifting with the position of the patient. A slight ecchymosis was to be seen at the lower part of the abdomen on the left side. After being put to bed the patient lay on his back with his legs drawn up, and any movement of the trunk was attended with severe pain. The man had a most anxious expression. The temperature was 97°; pulse 143. There were [illegible] of collapse. When he had

been taken into the Leopold ward, I was sent for. After admission the patient's symptoms rapidly increased in severity. The anxiety of countenance became more marked, the pain and desire to micturate more intense, and the abdomen more tender and distended. At 2 P.M. I found the symptoms as above detailed. On introducing a catheter, it seemed at first to hitch in the neighbourhood of the bulb, conveying the sensation of a false passage. The bladder was found to be contracted. Three ounces of dark brown-coloured bloody urine and clots were drawn off. The fluid was without smell. In consultation with Mr. Croft I decided that the evidence of intra-peritoneal rupture of the bladder was sufficiently strong to justify immediate abdominal section and exploration, and for this preparation was at once directed to be made.

Operation.—At 2.30 P.M. the patient was placed under the influence of ether by Mr. Lynch, the abdomen having been shaved and washed with 1 in 30 solution of carbolic acid. A red gum-elastic catheter, No. 9, was passed, and three or four more ounces of fluid were drawn off. The spray was used throughout. An incision about six inches in length, extending from an inch below the umbilicus to the symphysis pubis, was made through the abdominal walls, which were loaded with fat. The linea alba was sought for and divided. A great thickness of subperitoneal fat was also cut through before the peritoneum was exposed. At the lower part of the incision the fat appeared of a darker colour, as if recently bruised, but there was no extravasation into the *cavum Retzii* or sign of extra-peritoneal rupture. It was therefore decided to lay open the peritoneal cavity. As soon as this was done, a large quantity of clear fluid, serum and urine, quite free from odour, gushed from the abdominal cavity. Fifty ounces of this were collected, but a much larger quantity flowed down the sides of the abdomen and between the patient's legs, saturating the bedding. On introducing the finger the rent was at once detected. The bladder was now drawn forwards, a transverse incision of the peritoneum of half an inch being made on each side. An irregular obliquely placed rent in the bladder was then clearly exposed, situated at the upper and posterior part, and slightly to the left of the middle line; it was much more extensive in the outer than the inner wall, measuring two inches in length where the peritoneal covering and muscular coat were ruptured, and a quarter of an inch where the internal coat was torn. A blunt director passed into the wound came into contact with the catheter previously introduced. The rent in the bladder was closed by twelve fine silk sutures, rather less than a quarter of an inch apart; the ends were cut short. Each suture was passed by means of an ordinary fine curved needle introduced about a quarter of an inch distant from the margin. (Figs. 1 and 2.) The first and last pairs of sutures were passed through the bladder wall completely beyond the limits of the rent, so as to prevent the possibility of leakage from its extremities. On drawing the sutures tight, the closure of the rent seemed so complete and secure that no additional ones through the peritoneal coat appeared necessary. The bladder was then fully distended by injecting nine ounces of a warm boracic acid solution through the catheter, and found to be perfectly watertight. The abdominal cavity was thoroughly washed out with about two gallons of a 1 per cent. solution of boracic acid warmed to a temperature of 98°. The irrigator consisted of a large glass vessel raised four feet above the patient's abdomen, with a long indiarubber tube and glass nozzle attached. At first the fluid flowed out slightly tinged with blood; subsequently it became quite clear. There were no clots. Before the external wound was closed as much of the residual fluid as possible was expressed. No signs of inflammation could be detected in the peritoneum where it was exposed during the operation. The intestinal coats were free from injection; there was no adhesion or lymph visible. No vessels of importance were divided in the external wound, and all bleeding points were secured as they appeared, catgut ligatures being used. A suture was passed on each side, uniting the transversely divided edges of the peritoneum, and the abdominal wound and peritoneum were then united by eight stout silk sutures passed through the whole thickness of the abdominal wall. No drainage-tube was inserted in the peritoneal cavity, nor was a permanent catheter passed into the bladder, confidence being felt in the effective and complete manner in which the rent in the bladder was closed. A small, short drain was, however, inserted in the lower part of the external wound. Just before [illegible], a fit of vomiting came on. There was severe abdominal strain and a certain quantity of boracic fluid was forced up between the sutures. The operative proceedings lasted exactly two hours. The patient's pulse kept good, and the respiration was quiet and easy, except for a minute or two while the abdominal cavity was being washed out. Iodoform was powdered over the abdomen and groins. Iodoform gauze and salicylic wool were applied to the wound and kept in position by carbolic gauze and flannel bandages. The patient was lifted into bed and a pillow placed beneath his knees. A half-grain morphia suppository was introduced into the rectum. Before removal from the table the bladder was ascertained to be empty and the catheter was withdrawn.

The subsequent recovery of this man proved even more rapid than the last. He rallied very quickly after the operation, and expressed himself as feeling comfortable and free from pain. One hour after the temperature was 99·8°; pulse 104. Shortly after being put to bed he involuntarily passed three ounces of urine, and he continued to void a small quantity in this way at short intervals until the following day, when he regained partial control and passed some urine every two hours. The following day (the third) the control was complete, and he emptied the bladder every three or four hours without trouble. There was never any blood in the urine, and the quantity varied from thirty to forty ounces in the twenty-four hours. The temperature rose on the second and third days to 101°, and afterwards steadily declined to normal. The abdominal distension rapidly diminished, and he never felt any pain or tenderness on pressure. His only complaint at first was thirst and some pain from lying on his bruised buttocks. A week after the operation the external incision was found united throughout. The sutures were removed, and some strips of strapping applied to support the fat abdominal wall. At some of the suture openings the tension had caused some irritation, and a drop or two of pus was seen. On Nov. 28th (the twelfth day after the operation) the man was allowed to sit up, being apparently in all respects convalescent. He may now (Dec. 2nd) be regarded as quite well, only a fortnight having elapsed since the operation.

Remarks.—In the detailed account of these two cases there are several features of great interest. Both patients were adults, heavy, fat men. In neither was any other injury of importance present, and neither appears to have suffered any symptoms of collapse—a condition so commonly ascribed to a state of severe visceral lesion. In both, too, at the time of operation, the peritoneum was free from any trace of inflammatory change. The first patient walked home after the injury, and a distance of a mile from his house to the hospital on the following day. The second patient immediately drove to the hospital; but on examination by a most careful house-surgeon no symptoms directing attention to the bladder injury were observed. Whilst being examined the man stood up quite tranquilly, and apparently free from suffering. The only thing left undone, perhaps, was to pass a catheter, which would doubtless have drawn off bloody fluid. But for this there was no indication, as no desire to urinate was felt and the urine had been passed an hour before.

The success of the method by abdominal section must largely depend on matters of detail, and none can be more important than the method of suturing. The operation is not a new one. It had been suggested long ago by Benjamin Bell, who proposed in 1789 to suture the bladder after performing abdominal section. Grandchamps in 1826 sutured the bladder in animals, and proposed that it should be done in man. Blundell, an American surgeon, in 1840 proposed to suture the rent to the external wound. Larrey, Legouest, Gross, Cusack, Holmes, and probably others, have also advocated suture of the bladder after rupture. Nevertheless, in the discussion on Heath's and Willett's cases, the method by suture was considered by many of doubtful advantage, and in his recently published paper Guelterbock states that the practice of complete closure of the bladder wound adopted by Heath and Willett has in his opinion no future before it, that a supra-pubic opening left in the bladder for drainage is the important matter, and also that the toilette and drainage of the peritoneum before closing the external wound are of comparatively little moment. The accurate and complete suture of the bladder wound by sutures inserted through the whole thickness of the serous and muscular coats, carefully avoiding the mucous coats, is of the greatest importance. The serous surfaces should be inverted, brought into close contact, and the first and last stitches

inserted quite beyond the extremities of the wound, so that leakage at either angle, the most common place (Figs. 1 and 2) for it to occur, may be rendered impossible. Znamensky of Moscow, in an article on partial resection of the bladder in dogs,[10] lays the utmost stress on the accurate closure of the wound by sero-muscular sutures. Maksimow also attaches the greatest importance to this part of the operation from his experiments on dogs and rabbits, and so does Vincent of Lyons in a paper communicated to the Transactions of the International Medical Congress of London. In fact, in all the experiments it was clearly shown that success almost entirely depends

FIG. 1.

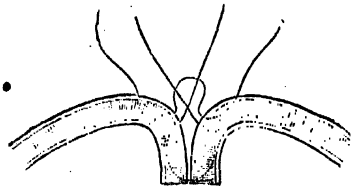

Diagram showing the edges inverted by the sero-muscular suture. The upper suture represents the serous suture, which is as a rule unnecessary.

upon the accuracy with which the sutures are placed. Vincent recommends a double row of sutures—one sero-muscular, one serous (Fig. 1),—but this is unnecessary. Znamensky abandoned the double row of sutures recommended by Vincent, because he found that sutures passed through the peritoneum only uniformly gave way, and on examination afterwards an ulcerated surface was found, while the deeper sero-muscular row of sutures could be seen between holding fast. Znamensky, Vincent, and Petersen recommend interrupted silk sutures as the best method and material to employ. I myself regard the double row of sutures as being unnecessary. The continuous

FIG. 2.

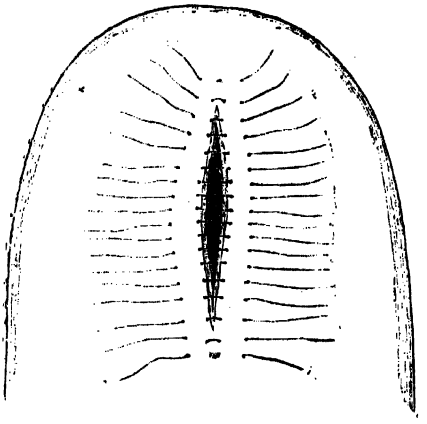

Diagram representing the manner of placing the interrupted sero-muscular sutures so as to approximate two surfaces of serous membrane when the sutures are drawn tight. It will be seen that two points of suture have been inserted at each end beyond the limits of the wound.

suture is the least desirable form. Opinions differ as to the comparative value of catgut, silk, and silver sutures. Catgut, I think, is not sufficiently reliable; silver is not very manageable. Experience shows us that carbolised silk is, on the whole, most efficient and trustworthy, and that buried silk sutures employed in aseptic operations may be safely left without risk of giving further trouble. Vincent employed silk in twenty-nine experiments, and never with any unfavourable consequence. It is not, however, the quality of the material so much as the manner in which it is employed that is of chief moment. The serous surfaces should be brought into contact by a sero-muscular suture and the mucous membrane always excluded. When the mucous coat has been traversed in animals the result has nearly always proved fatal. The mucous membrane falls between the edges of the wound on drawing the sutures tight, and hinders union. The loop of suture within the bladder is a foreign body, and salts are deposited on it. The urine may find a channel to the interior of the wound or the cavity of the peritoneum, through the points of passage of the sutures through the mucous membrane. The transverse division of the peritoneum on each side permits the bladder to be very fully drawn out of the wound, and is not the least likely to interfere with the future success of the operation. Whether the introduction of a rectal tampon be of greater advantage, I am not prepared to say. On trying it on the dead subject, I found that it somewhat raised, and certainly steadied, the recto-vesical cul-de-sac, and would thus probably render the deeper stitches more easy of introduction. I believe a free parietal incision important. Greater facility is thus afforded for inspection of the parts and for the introduction of sutures, the needful manipulations are rendered easier, while the intestines can be controlled and pushed upwards by flat sponges. Probably also the all-essential cleansing of the abdominal cavity can be more perfectly realised. The earlier the operation is performed the greater the prospect of success, hence prompt diagnosis becomes all important, and this should be followed by immediate action; but in doubtful cases I regard an exploratory operation as often justifiable. In itself it need not materially aggravate the danger to life, while it may prove the means of discovering the presence of a rupture previously only suspected to exist. If the deeper structures be first divided near the pubes, the anterior surface of the bladder can be exposed and examined before opening the peritoneal cavity. If a rent be found there, it may be unnecessary to proceed further; otherwise the serous cavity can be laid open and the upper and posterior surfaces of the bladder laid bare. No other manner of treatment seems likely to prove of real avail in rupture of the bladder. Lastly, great importance must be attached to the thorough washing out of the peritoneal cavity. The urine and bloody serum permeate everywhere. Wegner's experiments prove that extravasated urine does not merely gravitate, but that peristaltic movements of the bowel speedily distribute the fluid over the entire peritoneal surface. A 1 per cent. boric solution dissolved in previously boiled water and cooled to a temperature of 98° F. seems to me well adapted for the purpose, or water simply boiled can be employed.

As regards the interval after the injury at which the operation may be successfully undertaken, this may possibly prove greater than has hitherto been held. Mr. Rivington speaks of some period within the first twenty-four hours. In one of my cases twenty-six hours had elapsed, and, just as in the other case, without any sign of peritonitis having shown itself. In Mr. Brown's case no peritonitis was apparent after three days and a half; in Hamilton's, after five days and four hours. The mere presence of urine therefore, or urine and blood, in the peritoneal cavity, does not immediately set up inflammatory changes, as was once generally believed. In Professor Vincent's experiments, he states that in fifteen rabbits where the peritoneal cavity was flooded with urine for a longer or shorter period only three died. In a case of ovariotomy in my own practice, in which there were extensive and very firm adhesions, the bladder was torn through to the extent of three inches during an attempt to separate them. Although the catheter had been introduced immediately before the operation, the bladder contained several ounces of urine, which escaped into the peritoneal cavity. I sutured the bladder wound carefully, and the untoward occurrence was not followed by any bad consequence. The patient, although sixty-eight years old, made a good recovery in the usual time. Vincent, Julliard, Atlee, Pozzi, and Sonnenburg mention cases of a similar nature, which go far to prove that extensive intra-peritoneal injury to the bladder may be readily recovered from when it is promptly dealt with, as will be of necessity the case where it occurs during the performance of an ovariotomy. In ordinary traumatic cases of intra-peritoneal rupture of the bladder the margins of the rent are generally lacerated in appearance and soon become swollen. Rivington recommends paring these edges off, but when they are fully inverted by the method of suture paring [illegible] ary, and needlessly adds to

[10] Langenbeck's Archiv, 1885.

is in the upper and back part—the ordinary situation, in fact—it is, in my opinion, hurtful to perform perineal cystotomy, unless, indeed, in cases where the urethra is obstructed by stricture or rupture.

A drainage-tube introduced from the perineum into the bladder inflicts a further severe complication in cases of intra-peritoneal rupture. Vesical drainage can be effected through the urethra. In some cases the catheter *à demeure* may be indicated, but it is better practice surely to introduce a catheter each time the bladder has to be emptied if the patient be unable to void his urine. I think the prolonged detention of a catheter introduces a distinct element of risk; it favours the occurrence of septic decomposition within the bladder, and hinders the healing process in the rupture. If the rent be sutured effectively, the patient runs less risk from moderate distension of the bladder, which is all that can possibly occur in a case properly watched, than he does from the consequences of retaining a catheter for some days within the viscus. The experience of my two cases goes far to prove that the catheter may in many instances be safely dispensed with altogether. I am sure, too, an abdominal drainage-tube is not in most cases needful, and that its presence proves a source of danger to the patient. If the peritoneal cavity be thoroughly washed out the presence of a drainage-tube can scarcely be necessary. What watery fluid is left behind will be soon absorbed, and there is no surface from which bleeding can recur as from adhesions after a case of ovariotomy. Where peritonitis has already taken place, drainage, however, will be of advantage. The practice of making an opening in the superior fundus for drainage purposes, advised theoretically by Gueterbock, suggested also by Bryant in his "Practice of Surgery," and adopted by Pozzi and McGill, I should condemn in cases of intra-peritoneal rupture. It inflicts a further injury on the bladder, and can be dispensed with without incurring additional risk. Occlusive dressings can scarcely be effectively applied to the abdominal wound. The drainage opening must be left free, and as it is practically in contact with the remainder of the abdominal wound the advantages of antiseptic dressing cannot be realised.

Most authorities consider it unlikely that a rupture of the bladder should be overlooked, But in the earlier period, before the manifestation of the severer symptoms, this error, judging by past experience, seems not unlikely to occur. Many cases are upon record where the lesion was not diagnosed for several days, nor until the occurrence of severer symptoms not only made the nature of the injury clear, but completely contra-indicated operative interference. In fact, most of the symptoms usually ascribed to the presence of an intra-peritoneal rupture of the bladder may at first, and for some time, be entirely absent in some instances, and none of severity appear for several days.

I have not included the question of diagnosis in the scope of this communication. But I should say that, although there may be many cases where certainty of diagnosis is difficult to arrive at, yet the group of symptoms usually associated together, taken with the history of the injury, is in the majority of instances sufficient to render a correct diagnosis reasonably certain. Moreover, the only manner in which an uncertain diagnosis can be made certain is by practising an exploratory laparotomy with greater frequency. If this be done early enough, it will prove successful in uncomplicated cases, while the operation in itself scarcely aggravates the patient's condition, and is surely better than a hesitating, halting practice in expectation of improvement, which usually never takes place. I would strongly urge, therefore, the necessity for an earlier interference and bolder practice. The whole history of abdominal surgery points in this direction, and here we have to deal with a lesion in which recovery is otherwise admittedly hopeless.

Harley-street.

SURGICAL AID SOCIETY.—The twenty-fourth annual meeting of this charitable organisation was held on the 6th inst., the Lord Mayor presiding. During the past year the Society has relieved 6412 persons, including 2311 men, 3156 women, and 945 children, or an average of 123 a week; while the total number of patients assisted by the Society since it was called into existence is 58,587. The total income for the year was £5485, of which £3469 were derived from annual subscriptions, being an [illegible] of £310. The expenditure amounted [illegible] to £380

LITHOLAPAXY IN MALE CHILDREN AND MALE ADULTS.

BY SURGEON-MAJOR D. F. KEEGAN, M.D. DUB.,
RESIDENCY SURGEON, INDORE, CENTRAL INDIA.

(*Continued from page 1071.*)

CASE 38.—K——, a boy aged two years and a half, was admitted into hospital on June 9th, 1885, suffering from stone symptoms, which had existed for three months. A No. 7 lithotrite and a No. 7 evacuating catheter passed readily into the bladder. It was not considered necessary to incise the meatus. The lithotrite was introduced into the bladder on four different occasions. On its last withdrawal from the bladder, the meatus of the urethra was torn slightly, as some of the débris had got clogged between the blades of the lithotrite, thus increasing the size of the lithotrite from a No. 7 to perhaps a No. 7·5. Weight of stone removed 11 grs., and consisting of uric acid. Time occupied in operation seventeen minutes.—10th: Urine clear; boy cries much when passing urine.—12th: Patient doing well; urine clear, much less pain in passing urine. 13th: Patient feels much better. The boy's father, living not far from Indore, took the child home. On July 26th the father brought the boy to the hospital to show him to me. The boy had grown plump, and had continued to pass urine without pain and with perfect freedom.

CASE 39.—M. A. K——, a boy aged two years and nine months, was admitted into hospital on July 8th, 1885, with stone symptoms, which had existed for three months. Urine clear and acid in reaction. There is great straining in passing urine, which comes away drop by drop. Evening temperature 100·6°. Next day a No. 8 lithotrite passed readily into the bladder. Lithotrite introduced five times. A No. 7 evacuating catheter employed to remove the débris. Stone weighed 32 grs., brick-dust colour, consisting principally of uric acid. Operation lasted thirty-one minutes. 10th: Urine quite clear; slight pain in micturating.—12th: No pain in passing urine, and the father took the boy home. On the 19th the father brought him to the hospital for inspection. The boy complained of no symptoms of stone, and passed urine quite freely and without pain.

CASE 53.—G——, a boy aged three years and three months, was admitted into hospital on February 6th, 1886. When sounded, a stone was detected. Chloroform having been administered, I tried to pass a No. 9 and then a No. 8 evacuating catheter, but found the meatus of the urethra too small to permit their passing. I then introduced without any difficulty a No. 7 evacuating catheter into the bladder, into which I injected some tepid water. A partially fenestrated No. 8 lithotrite was then passed with ease. When in the bladder, and before attempting to seize the stone, I opened the blades of the lithotrite very slightly by working the screw action. I did so to allow for clogging, and then withdrew the lithotrite, thus slightly opened, with the greatest ease through the membranous portion of the urethra. When coming through the meatus of the urethra the lithotrite ruptured it (the meatus) and caused a little bleeding. I then screwed home the lithotrite and passed it again into the bladder, and immediately struck the calculus, but found great difficulty in seizing it. The stone seemed to me to be quite spherical, for it slipped from out the blades of the lithotrite on several occasions. I seldom recollect having experienced so much difficulty in seizing a stone as I did on this occasion. However, after some thirteen minutes' duration, I at last succeeded, and then crushed it readily. After the crushing, a No. 8 and then a No. 9 evacuating catheter passed with ease into this boy's bladder. Indeed, I feel quite certain that I could have passed a No. 10, or perhaps even a No. 12, evacuating catheter, if I had found it necessary or advisable to do so, *once the meatus of the urethra had been ruptured.* Owing to the great difficulty experienced in seizing the stone the operation lasted thirty-seven minutes, although the stone weighed only 70 grs.—Feb. 7th: No pain on pressure being made over the bladder or course of the urethra; pain in passing urine less than it was prior to the operation.—8th: Urine clear and pale; no pain over bladder or urethra; no fever; pain in passing urine less.—12th: Child placed under chloroform, and

bladder explored with Sir H. Thompson's sound. No particle of stone could be detected. No click heard on working the aspirator.—13th: Patient quite well; allowed to go home, distant about forty miles from Indore.

Remarks.—The history of this case well exemplifies the fact that, although the meatus of the urethra is sometimes very small in young boys, the size or calibre of the urethra itself may nevertheless be very large. Had I incised the meatus of the urethra before introducing the No. 8 partially fenestrated lithotrite, I might have dispensed with the precaution of opening its blades in the bladder, because I should have at the outset learnt that the lithotrite was, so to speak, an easy fit for the urethra. I opened the blades of the lithotrite when in the bladder because, from the sensation conveyed to my hand on first passing the lithotrite, I thought that if the instrument were to become clogged by débris I should experience some trouble and difficulty in withdrawing it through the membranous portion of the urethra. A lithotrite, when being passed through the urethra, if it happens to be gripped merely by the meatus, still conveys to the hand of the operator the impression that the lithotrite is a tight fit for the whole length of the urethra, when, as a matter of fact, the urethra itself would accommodate a lithotrite a size or two larger if the constriction existing at the meatus were removed in the first instance by means of an incision. And here I would like to make some observations on the kind of lithotrite which experience has taught me is best adapted to the performance of litholapaxy in male children. Unquestionably the best, and indeed the only perfectly safe, form of lithotrite to use in performing litholapaxy in young boys is the *completely fenestrated* pattern of lithotrite. A partially fenestrated lithotrite is liable to get clogged with débris, and may sometimes retain within its blades a thin sharp projecting fragment of stone, which would lacerate the urethra on the withdrawal of the lithotrite from the bladder. Clogging of the blades of a lithotrite with débris is a very dangerous complication in performing litholapaxy in male children, because it has the effect of increasing the size or number of the lithotrite, say, from a No. 7 to a No. 8 (English scale). And as in performing litholapaxy in male children we are dealing with urethræ in which there is, so to speak, not much spare room left to work in, the effect of increasing the size or number of the lithotrite might be such that in its withdrawal from the bladder the urethra might get unduly stretched or ruptured. Now, it is impossible that clogging can occur, or that thin, sharp fragments of stone can project, between the blades of a completely fenestrated lithotrite. Objecting to the employment of a partially fenestrated lithotrite in performing litholapaxy in male children for the reasons already stated, I can only characterise the use of a flat-bladed unfenestrated instrument in operating on this class of patients as unwarrantable and absolutely dangerous. Since the operation in the case just detailed I have received from Messrs. Weiss and Son, of London, a completely fenestrated lithotrite, which is No. 6 in the stem and No. 8 in the angle (English scale), and with this instrument I performed litholapaxy on three young male children shortly before leaving India. Since my arrival in England the same firm have constructed for me a still smaller instrument, which is No. 6 in the stem and No. 6 in the angle (English scale). This instrument will pass readily through the urethræ of the great majority of boys of between two and three years of age, and is perfectly capable of disposing of stones weighing up to two drachms. I exhibited these two patterns of lithotrite at the recent meeting of the British Medical Association held at Brighton, and they are miniatures of of the lithotrite shown as Fig. 2 on page 10 of Freyer's work on Litholapaxy, recently published.

Having now related perhaps sufficient examples of cases in which I performed litholapaxy for the removal of small stones in very young boys, I shall proceed to detail a few cases in which I removed by this operation stones of considerable size from older boys.

CASE 37.—V——, a boy aged ten, was admitted into the Indore Hospital on May 26th, 1885, suffering from stone symptoms, which had existed for six years. His spleen was greatly enlarged. Urine neutral and clear. Next day, being placed under chloroform, a No. 8 lithotrite was passed into his bladder, when a large stone was easily seized and crushed. A No. 9 evacuating catheter was then introduced with ease. The lithotrite was passed six different times, and the operation lasted as long as ninety-four minutes. The stone was composed of uric acid and phosphates, weighed 360 grains, and was completely removed at one sitting.—May 28th: Pain along course of urethra and over bladder region; pain also on micturition. At the root of the penis there is a slight swelling.—May 29th: Swelling less, also pain on micturition; urine quite clear.—31st: Swelling at root of penis diminishing; some pain along the course of the urethra when pressure is made; eats well.—June 4th: All swelling disappeared; micturates freely and without pain; complains of pain over region of spleen. Discharged as cured of stone, and readmitted for the treatment of splenic enlargement. Left hospital for his home on June 9th.

CASE 44.—R——, a boy aged nine years and a half, was admitted into hospital on Aug. 18th, 1885, with stone in the bladder. Urine alkaline and turbid; specific gravity 1014; a trace of albumen. Next day, being placed under chloroform, the meatus of the urethra was incised, when evacuating catheters Nos. 9, 11, 13, and 14 were passed with ease. Lithotrites Nos. 8, 10, 11, 14, and 15 were then passed, but the stone proved too large for all these, with the exception of the last. The stone was eventually seized and crushed. The operation lasted as long as three hours and two minutes, and the urine in the aspirator was clear to the end.—20th: There is great pain over the urethra and over the bladder region when deep pressure is made; considerable pain in passing urine; colour of urine reddish-brown.—21st: General condition unchanged; urine light brown.—22nd: Pain over bladder region and urethra much less; has fever.—23rd: Fever less.—24th: Penis is swollen.—26th: Much better; pain over bladder and in passing urine much less; swelling of penis much diminished.—28th: Feels quite well now; walks about the hospital verandah.—Sept. 1st: Gone home quite well.

Remarks.—The stone in this case weighed 700 grains, and consisted chiefly of uric acid, with a nucleus of oxalate of lime and a thin covering of phosphates. My friend, Surgeon-Major Caldecott, removed this stone during my absence from Indore on leave. It is the largest that we have as yet removed from a boy's bladder at the Indore Charitable Hospital. Had this boy been cut, he would, in all probability, have remained in hospital for five or six weeks before being discharged; and had his urethra proved less capacious than it was, litholapaxy would have been impracticable. Had his lines been cast in London in the present day, he would most probably have been subjected to Petersen's modification of supra-pubic lithotomy.

CASE 46.—S——, a boy aged twelve, was admitted into hospital on Sept. 30th, 1885, with symptoms of stone, which had existed for one year. Specific gravity of urine 1026; alkaline in reaction; no albumen; deposits phosphates on standing. Being placed under chloroform, Nos. 11 and 14 lithotrites were passed with ease. An oxalate of lime calculus weighing 344 grains was removed in sixty-two minutes. Respiration of patient stopped suddenly during operation, but he revived under artificial respiration; colour of urine quite clear in aspirator throughout the operation.—Oct. 1st: No pain over urethra or bladder. Urine quite clear and of amber colour; has no pain in passing urine.—2nd: Feels perfectly well; colour of urine normal; wishes to go home.—3rd: Quite well; allowed to go home.

Remarks.—Compare the history of this case after the operation of litholapaxy with what it would have been had the stone been extracted by lateral lithotomy. This boy was practically well the day after the operation.

In the table giving the details of fifty-eight litholapaxies performed at the Indore Hospital there is one fatal case, the history of which I have given at some length at pages 135 and 136 in the May number of the *Indian Medical Gazette* for 1884. Suffice it to say on the present occasion that had the previous history of this case been carefully noted on the boy's admission into hospital, lateral lithotomy, and not litholapaxy, would have been performed. The nucleus of the stone in this case was a long piece of "tilli"[1] stalk, which had penetrated the bladder through the rectum and had broken off inside the former. It was a case eminently suited to lateral or supra-pubic lithotomy. I have included this case in the table of litholapaxies, although it really does not fairly come under this category, for my assistant in the first instance attempted to treat this case by lithotrity, and on two subsequent occasions I endeavoured

[1] Didynamia angiosperma. Sesamum. Schreb-gen, N. 1048. Is annual and in good soils three or four feet high. Of

to remove the foreign body and its encrustation by the lithotrite and an evacuating catheter. The case altogether was a very unfortunate one, and exemplifies the great importance of carefully going into the previous history of every case before an operation is undertaken. I think, however, that any of my readers who will refer to the history of this case in the pages of the above-quoted medical journal will agree with me when I state that the fatal termination in this one solitary case should not be considered as militating against the performance of litholapaxy in male children.

There is one other case in the table which, being of special interest, I shall detail at some length. Although in this case the operation of litholapaxy in itself was completely successful, I was subsequently afforded an opportunity of examining the bladder and urethra post mortem, the immediate cause of death being due to anæmia and epistaxis.

CASE 54.—L— —, a Hindu lad aged fourteen years, was admitted into hospital on Feb. 11th, 1886, with symptoms of stone which had existed for two years. He was greatly emaciated: sunken jaws and prominent teeth; spleen much enlarged; most anæmic. He had travelled a long distance to reach Indore; his sufferings were very great, and he begged to be operated on at once. Urine contained about one-third albumen. Next day, being placed under chloroform, a fawn-coloured uric acid calculus, weighing 248 grains, was evacuated from the bladder in sixty minutes. A No. 11 lithotrite was passed with the greatest ease into the bladder, and the operation presented no special features of interest or difficulty.—Feb. 13th: Morning temperature 104·5°. No pain on pressure over bladder; some pain along the course of the urethra; pain in passing urine great; colour of urine reddish-brown. Evening temperature 104·4°. Linseed-tea, milk, and diaphoretic mixture every third hour.—14th: Morning temperature 101·6°; pulse 120. Had five thin motions during the night; colour of urine clear brown; some pain in passing urine. Port wine and lead and opium pills ordered. Evening temperature 99·8°.—15th: Slept well; feels very languid; no desire for food. Morning temperature 98·4°; evening, 102°; pulse 120.—16th: Has great pain over the splenic region and in the left loin, for which morphia was injected hypodermically.—17th: Morning temperature 100·8°; pulse 120; no pain in abdomen; passes urine in a good stream.—18th: Had two thin motions during the night; slight epistaxis; quinine and sulphuric acid prescribed.—19th: No fever; pulse 108; feels slight pain in passing urine.—20th: Had four motions during the night; morning temperature 97°; pulse 96; tongue clean; feels better; biniodide of mercury ointment rubbed over spleen.—23rd: Has no urinary symptoms whatever; discharged as cured of stone in the bladder, and readmitted for hypertrophy of spleen and debility. From this date up to March 2nd, the lad used to walk about the hospital grounds.—March 3rd: Has some pain in left loin.—4th: Has great pain in left loin over kidney. From this date up to March 13th he had much pain in both loins; latterly the pain was greater in the right loin, and presence of stone in the right kidney was suspected. Very weak and anæmic.—14th: Had bleeding from the nose during the night; tampon applied.—15th: Epistaxis stopped by tampon; pain in the right loin less.—16th: The tampon being removed, epistaxis recurred; tampon reapplied; blood which came from nose thin, pale, and watery; very weak.—17th: Patient died early this morning. The post-mortem appearances six hours after death were as follows. The bladder and urethra were found free from organic disease, though very anæmic; lining membrane of bladder and urethra perfectly smooth; urine drawn off after death perfectly clear. No particle of calculus found in bladder; spleen much enlarged, presenting the usual features of malarious hypertrophy. Left kidney flabby and pale; a small abscess found in its cortical substance; some grains of uric acid found in the pelvis. Right kidney: On making a section, a large uric acid calculus was found filling up the pelvis and infundibula; indeed, the stone formed a perfect cast of the pelvis and infundibula, and several processes of the stone were embedded in the papillæ of the kidney. Weight of kidney calculus, 80 grains. Heart pale and somewhat flabby.

Remarks.—I think I am justified in returning this case amongst the number of successful litholapaxies performed at the Indore Hospital. I feel quite certain that if I had performed lateral lithotomy [illegible] removal of the stone from this boy's bladder, he would most probably have died of exhaustion and diarrhœa a few weeks after the operation. The most ardent advocates of lateral or supra-pubic lithotomy would not, I think, assert that the final result in this case would have been different from what it was, had the stone been extracted by one or other of these methods. Although the presence of a stone in the right kidney was suspected during life, the boy's general condition contra-indicated all further operative interference. Extirpation of the right kidney could have done no good, as the left kidney was also much diseased. The history of this very interesting case strengthens the opinion I had already formed respecting the superiority of litholapaxy over lateral lithotomy in the treatment of stone in boys in suitable cases.

(To be continued.)

EXPERIMENTAL RESEARCHES CONCERNING PASTEUR'S PROPHYLACTIC.[1]

BY T. WHITESIDE HIME, A.B., M.B. DUB.

DR. HIME referred at the commencement of his paper to the difficulties which were placed in the way of scientific research in this country in all that concerned the life and well-being of man and the higher animals. Physiological and pathological research were practically dead in England, killed through the unreasoning proceedings of those who were not in a position to estimate correctly the results of their action in the matter. Fortunately there was no difficulty in pursuing such researches abroad. For some months he had been, in Paris, unremittingly engaged in studying Pasteur's method, and availing himself of the extreme kindness and generosity of the Professor in following the practice of his laboratory. The affability with which Pasteur received all comers, and the candour and want of reserve with which he explained and demonstrated his methods to all earnest inquirers, were in his experience unequalled, and worthy of imitation everywhere. It was unavoidable that the subject of rabies should be unfamiliar to the vast majority. It was not given to every man to have a supply of the virus at his disposal. The number of cases and deaths from rabies in this country was comparatively so small that few medical men had ever seen such, and Pasteur's method of treatment was still more unfamiliar, except through such inaccurate and unscientific *canards* as were published in the daily papers. Hence to some extent the attitude of the profession in this country, which had preserved a cold silence on the subject. Hence also the boldness of the few critics who had ventured to oppose Pasteur. Spitzka of New York was one of these critics. His familiarity with Pasteur's method was strangely illustrated by his request, published in the *British Medical Journal*, to be informed what are the symptoms of rabies in the rabbit; while his experimental skill in the practice of the method was shown by his statement that it is "a very difficult matter to keep any rabbit inoculated with fresh brain material by trephining alive" (see *Brit. Med. Journ.*, Oct. 30th, 1886). Dr. Hime could assert from personal knowledge that there is no more difficulty in keeping a rabbit alive in such circumstances than in keeping an infant alive after vaccination. The interference with physiological function in the former case, if the operation be done by an operator skilled in the method, is nothing like so marked as in the latter, there being no fever, no loss of appetite, no restlessness, and no local symptoms. Another critic in this country had shown himself possessed of more dialectic skill, but he, too, was entirely ignorant of the practice of Pasteur's method; he had never seen the practice in Pasteur's laboratory; he had never seen any other person perform the inoculation; he had never done it himself, and had never seen either a living or dead rabbit which had been so inoculated, yet he could criticise the method, and take Pasteur to task (without a shadow of reason) for not performing control experiments! Having devoted himself to the study of the question for months in Paris and performed numerous experiments, Dr. Hime wished to bring some of them before the Society, which he desired them to regard as types of many others having the same result, and not as isolated. He had selected them especially

[1] Abstract of a paper read at the Pathological Society on Dec. 7th, 1886.

to bring before the Society, because they were, he thought, important in themselves, and, further, they met the objections raised against Pasteur's method in this country. To save the time of the Society, he gave the results in narrative form, without entering into minute details of each. But the facts which he would detail were all within his own knowledge. He intentionally avoided entering on the statistical question of results, because he believed such were foreign to the business of the Society; but he believed the success of Pasteur's treatment had been brilliantly demonstrated by statistics as well as by experiment. That the disease in the rabbit from which Pasteur obtained his material for human inoculations was true rabies was indubitable. Nerve matter taken from such a rabbit and inoculated on a dog intracranially, the only certain method, invariably produces true rabies. If nerve matter be taken from a human being dead from an attack of canine rabies, and be inoculated on a rabbit, a guinea-pig, and a dog, all three will take rabies and die. The dog will have rabies according to his kind, with symptoms either of the dumb or furious character. The guinea-pig will exhibit very characteristic symptoms, and the rabbit will develop the symptoms peculiar to its kind—such as, for convenience, may be called the "Pasteurian disease."[2] But an interesting and important fact must be borne in mind. The virus used for the experiment, being canine virus which has passed once through the human subject, will retain certain canine peculiarities as to period of incubation, date of death, &c. If instead of human nerve tissue from persons who have died of canine rabies we employ nerve matter direct from a dog which has died of rabies for inoculation, the animal will be similarly affected, and the disease produced in the rabbit cannot be distinguished from that caused by inoculation with nerve matter taken from a human being who has died of rabies after inoculation with canine virus. If again, nerve matter be used taken from one of the rabbits employed by Pasteur for protective inoculation, the same result will be obtained, with this difference—the course of the disease in the various animals will be shorter. Pasteur uses for his protective inoculation virus which, originating in ordinary canine rabies, has been passed directly from rabbit to rabbit for some hundreds of series. The result is that the virus has become intensified, and kills more rapidly than the original canine virus. It was actually alleged at one time that the deaths following Pasteur's inoculations were due to them. This was triumphantly disproved by the experimental demonstration that the virus in the deceased was canine virus (originating in the original bite), and not rabbit virus inoculated by Pasteur for protection. The opposite result is obtained if the virus be passed from monkey to monkey through a long series: the virus becomes weaker and weaker. But no doubt, just as the virus of anthrax or fowl cholera, which has been modified by cultivation, could be brought back to its primitive virulence, so the weakened rabic virus of the ape and the intensified rabic virus of the rabbit could be brought back to their original degree of virulence. If Pasteurian virus be passed through the dog once, and then be inoculated on a rabbit, it will be found not to have resumed canine characteristics by passing once through the dog. But more frequent passages through the dog would probably restore its primitive characteristics. The symptoms are very special in the rabbit inoculated with Pasteurian virus; the length of the incubative period (five to six days) and the date of death (nine to ten days) are more invariable than in any other disease of man or animal known to Dr. Hime. Further, the symptoms are very characteristic and invariable, notably the slightness of the general symptoms, even after paralysis has become marked. The temperature[3] also is very interesting, and markedly different from that found after intra-cranial inoculation with other materials than the Pasteurian virus or rabic virus from some other source. The following is a characteristic chart of the temperature of a rabbit which died of the Pasteurian rabies:—

First day	{102·6°[4] 102·2°[5]}	Sixth day	105·6°
Second day	103·0°	Seventh day	105·8°
Third day	102·8°	Eighth day	104·4°
Fourth day	103·0°	Ninth day	104·1°
Fifth day	104·2°	Tenth day	97·0°
		Eleventh day ...	86·0°[6]

The febrile stage may be shorter, and the fall more gradual, but the latter is always great. The elevation is not always so great as in this example, but the rhythm is characteristic, and the temperature usually gives indications before the actual symptoms appear. The course of the temperature in the rabid dog is similar. At first there is no change, then the temperature rises rapidly, and may reach 105° or 106°; the period of acme lasts one or two days, and is succeeded by a very rapid fall to about 84·6°, when death ensues. The fact that the disease is always and invariably transmissible by inoculation is of great importance as regards its pathology, and as distinguishing it from other diseases.

With regard to post-mortem appearances in the Pasteurian rabbit, there is nothing pathognomonic, any more than in the dog or the human subject dead from rabies; all the organs appear free from disease, some more or less hyperæmic; and sometimes hæmorrhages are found; the brain is slightly hyperæmic as a rule, the heart contracted, and the bladder generally full. The stomach almost invariably contains food; the cæcum is commonly full, and the remainder of the intestine generally contains but little, and the small intestine nothing. This absence of morbid conditions is remarkable, and is certainly not found after death from injury to the brain in the operation, nor after death from intra-cranial injection of other materials—e.g., putrid material. In this case pus will be found within the cranium, and other evidences of purulent absorption will be detected. It is alleged by Dr. Dolan (*Brit. Med. Journ.*, Sept. 4th, 1886, p. 475, line 15 from the bottom) that the inoculations are made "into the rabbit's medulla," and that "the same kind of affection in rabbits can be produced by injecting almost any kind of diseased material into the same region." The injection is not made into the medulla, nor into any part of the nervous system. It is made into the space beneath the dura mater and pia mater, and the brain is not injured or touched by the instrument in a successful operation. The medulla, indeed, could not be reached at all (as suggested by Dr. Dolan) from the site of the inoculation, without traversing almost the entire mass of brain. But even if the brain were injured (and it certainly is not, as specimens exhibited prove[7]), mechanical lesions of the brain or medulla do not produce a specific contagious disease indefinitely transmissible by inoculation, and presenting the symptoms of the Pasteurian disease. These are certainly not the symptoms of injury to the brain or of any part of the nervous system. The allegation that injection of "almost any other kind of diseased material" will produce the symptoms can only be disproved by experiment. Intra-cranial injection of sterilised bouillon will not produce the symptoms of the Pasteurian disease nor any other morbid symptoms, and rabbits so injected will not die if skilfully operated on. Rabbits inoculated according to Pasteur's method with sterilised bouillon rubbed up with putrid meat will die, but with symptoms entirely different from those of the Pasteurian disease, and without the characteristic paralysis and temperature. But still more noteworthy is the fact that the disease produced by injecting putrid material is not transmissible. If fresh nerve matter be taken from a rabbit which has died in consequence of disease produced by intra-cranial injection of putrid matter, and be injected intra-cranially (according to Pasteur's method) on another rabbit, the latter will not die, and will have no specific disease whatever, nor marked symptoms of any kind, if skilfully operated

[2] Dr Hime stated that he merely used this term for brevity's sake, without special reference to the fact that the period of incubation and the period elapsing before death have been shortened in the rabbits used by Pasteur for preventive inoculations. This shortening of these periods does not alter the nature of the disease, any more than the nature of the virus in a case of typhoid or scarlet fever is altered because in particular conditions it may kill in ten or three days respectively, instead of in twenty or in six days.

[3] The normal temperature of the rabbit and of the dog is about 102° F. Variation will be found in accordance to age, and probably race, but not to a very large extent. Taking the temperature of rabid dogs is a very dangerous performance, but with experience it can be readily done. Dr. Hime has seen many furious rabid dogs apparently so astonished at his audacity in putting a thermometer up their rectum that they have stood as if mesmerised or cataleptic for ten minutes without a movement.

[4] Immediately before inoculation. [5] Immediately after inoculation.

[6] Death.

[7] One was a rabbit's skull and brain injected, after trephining, according to Pasteur's method, with a coloured solution of gelatine. The gelatine was seen solidified on the surface of the pia mater, the brain being intact, and the whole being a distinct demonstration of the method of performing Pasteur's operation. Another interesting specimen exhibited by Dr. Hime was a fresh preparation of a rabbit's brain inoculated in Pasteur's laboratory [illegible] Dec. 4th ult. The skull-cap was removed showing the [illegible] slightest injury.

on. But the Pasteurian disease is always transmissible by intra-cranial injection. If the same bouillon as used in these operations be rubbed up with fresh brain matter from a healthy dog, and injected into a rabbit according to Pasteur's method, the rabbit will not die, notwithstanding Spitzka's statement to the contrary, and will not exhibit one symptom of the Pasteurian rabbit, which always dies. It is hardly necessary to add that intentional lesion of the rabbit's brain in the performance of a dummy Pasteurian operation, when nothing at all is injected, does not necessarily cause death, and if it does the symptoms are utterly different from those of the rabbit which has died of the Pasteurian disease or from putrid infection, and inoculations made from such a rabbit will not cause death. Nerve matter from dogs which have been suspected of rabies, and have died, or been killed in consequence, has frequently been injected intra-cranially on rabbits as a diagnostic. If the dogs were rabid, the Pasteurian disease will be developed in the rabbits; if not, the rabbits will survive, without showing any symptoms of this disease, or of any other disease. That this crucial method of diagnosis exists is due to Pasteur; that it cannot be applied so as to settle every doubtful case is the result of British legislation. In fine, the following results are established: The virus used by Pasteur for protective inoculations originated in the rabid dog, and is the virus of rabies. Pasteur had published results showing that the material used for his later protective inoculations of man caused rabies in animals which were unprotected. If virus be taken from a rabid dog and be passed through a series of rabbits it will produce the same disease as is developed in the rabbits from which Pasteur takes his matter for preventive inoculations. If the virus from such rabbits be inoculated back into the dog or other susceptible animal, it will produce true rabies in them, and if then passed back to the rabbit it will reproduce the same symptoms *ad infinitum*. Human rabies, if inoculated on the rabbit, will produce the same symptoms, with such variations only as are due to its origination in the dog, cat, &c. These variations are exhibited chiefly in the length of the period of incubation, and the period elapsing before death, the disease invariably terminating fatally. No other known disease produces the same results, nor can the symptoms be caused either by surgical brain lesion or the intra-cranial injection of inert material such as sterilised bouillon, or with putrid material. The Pasteurian disease is specific, and very distinctly characterised by its course and symptoms, which are different from those of any other disease; it invariably ends fatally, and is indefinitely transmissible by inoculation from animal to animal. Dr. Hime did not enter into the question of the success of Pasteur's treatment, but stated that the protection afforded to dogs by Pasteur was proved beyond doubt or question, and analogy would suggest that the same method was applicable to man. Dogs could be protected either by inoculation before infection or afterwards. Further, they had been protected against the action of the rabbit virus, which is much more active than ordinary canine virus. The reality of this protection established the truth of Pasteur's principle. That his practice was capable of improvement was not improbable; but he had already effected a great deal in a short time. It has been objected that the inoculated prophylactic virus is inert because the patients show no specific reaction. A foolish objection. As well say arsenic is inert because a patient taking it shows no toxic symptoms. Indeed, Dr. Hime was inclined to think that there was a decided though slight reaction. He himself had experienced local symptoms and distinct axillary tenderness, and in others these were more marked still. He had made numerous thermometric observations on patients under treatment, but so far could not assert that there was any characteristic thermal change. Some, while admitting that protection had been afforded by Pasteur after slight wounds, denied that this was true in severe ones. These persons at least admitted the scientific basis of Pasteur's method. But of Pasteur's patients persons most seriously wounded by rabid animals had escaped, and, Dr. Hime believed, entirely owing to the treatment. The accuracy of the method being admitted, he thought this objection was not only in fact unfounded, but was at most one of detail. Finally, from the fact of the extraordinary low mortality—little over 1 per cent.—corroborative evidence was obtained. The rabid condition of the animals in a large number of these cases was proved either by experimental inoculation or by certificates from veterinary surgeons. [illegible] no doubtful cases, these being purposely omitted. Dr. Hime expressed his opinion that Pasteur had established a true prophylactic treatment against rabies, one of the most formidable and hitherto intractable diseases. He had thus crowned a glorious career of research directed to the benefit of man by a most notable discovery, primarily salutary to man himself. The establishment of a Pasteur Institute in this country, he thought, was called for, and such institutions were already established in Paris, Moscow, St. Petersburg, Odessa, Samara, Varsovia, Naples, and Milan. Turin and New York will soon be provided with such institutions. The English public were still vainly waiting for the report of the Royal Commission of inquiry into this subject. While this report was being prepared other countries were acting, and we were satisfied to send our patients to Paris for treatment instead of making provision for them in England.

UNUSUAL CASE OF ORBITAL TUMOUR.

BY T. H. BICKERTON,

LATE CLINICAL ASSISTANT, ROYAL OPHTHALMIC HOSPITAL, MOORFIELDS.

MRS. G——, aged forty-seven, came under my notice, through the kindness of Dr. Oxley, on July 31st, 1886, on account of slight dimness of vision of the right eye; but what greatly attracted attention, as may be judged from the accompanying illustrations, was the condition of the left orbital region, which was concealed by a large shade, and

which she was only with difficulty induced to uncover. She gave the following history: When she was ten years of age a small boy struck her in the left eye with his fist, the blow causing great pain. The pain continuing, and the eye at the end of six weeks being noticed to be "swelled out," she

was taken to the Glasgow Eye Infirmary. Here she was seen by Mr. Mackenzie, and the notes then taken indicate the condition of affairs at that time and for a lengthened period afterwards. For these notes I have to thank Dr.

William Wallace, the present house-surgeon of that institution, who kindly sent me a *verbatim* copy of the report, which runs as follows:—

"March 4th, 1850: Mary B——, aged eleven. Exophthalmos of left eye consequent on a blow. Complains of pain in forehead. Vision of this eye enables her to see characters an inch long. Pot. iodid., gr. i., t. d. s.—9th: Pot. iodid., gr. ii., t. d. s.—13th: Three leeches to left temple.—17th: Eye seems rather less prominent.—27th: Repeat leeches.—April 4th: Blister behind ear.—11th: Repeat blister.—Sept. 8th: Is reported to be worse. Repeat blister and leeches.—Aug. 23rd, 1851: Much the same. Pot. iodid., gr. 3¾, t. d.—Sept. 12th, 1851: Exophthalmos seems rather less.—March 28th, 1854: Exophthalmos much increased. Hydrarg. bichlor., gr. ¼; ammon. muriat., gr. ½, t. d.—April 29th, 1854: No improvement. Stop the bichloride.—April 18th, 1855: Exophthalmos increased. On lifting the upper lid the glandulæ congregatæ are found increased, and the lacrymal gland enlarged. Sept. 3rd, 1856: Tumour seems stationary. Lower sinus of conjunctiva, being infiltrated and swollen, was snipped off."

The patient states she has a distinct recollection that on one occasion she was given chloroform for the purpose of having the swelling punctured, but no account of this operation can be found by Dr. Wallace. From this time (Sept. 3rd, 1856) until July 31st, 1886, an interval of thirty years, she has not allowed a medical man to see the eye. Her account of the progress of the swelling since that time is that it has gone on increasing very slowly in prominence and in size in all directions; that she has been a martyr to pain during the whole of this period, and is never without it, except when asleep. At times the pain is of a dull aching character, at times sharp and stabbing. It frequently, by its severity, confines her to bed for days and weeks, and on occasions it is so severe that it brings on vomiting, the vomiting being unaccompanied by any feeling of nausea. Her experience is that the pain is always relieved to a greater or less extent by the recumbent position, and this, with the constant applications of cold wet cloths and cold bread poultices to the swelling in order to "cool it down," have been the only palliative measures adopted.

Present condition.—On removing the large shade there is to be seen an enormous tumour, which, occupying the socket, and extending in all directions, has pushed the eyeball far beyond the limits of the orbit, the eyeball forming the apex of the tumour. The upper and lower lids are tightly stretched, reddish purple in colour, the superficial veins standing out like pieces of whipcord. These appearances are more marked in the upper than in the lower lid. Projecting between the eyelids is the eyeball, which is unaltered in size and shape. The upper two-thirds of the cornea are clear, the lower third is semi-opaque. The pupil is 2 mm. wide and immobile, but it acts faintly to stimulation of the right retina. The right pupil has a width of 3 mm. The conjunctiva, ocular and palpebral, is red and swollen, and the lower tarsal fold is turned inside out. Lacrymation goes on at the regular rate of about one drop per minute, the drop falling from the centre of the lid. Movement of the eye is *nil*. Sight is lost except for light and shade. The length of the left palpebral aperture is two inches; that of the right is one inch. Tension of the globe + 3. The measurements of the tumour are: Circumference at base, measured by string, 8½ in.; greatest vertical length of the anterior surface, 4$\frac{4}{10}$ in. The apex (formed by the cornea) of the tumour projects from the temporal angle about 3 in., and from the cornea of the right eye about 2½ in. The tumour is about as hard as cartilage, slightly nodulated, but has nowhere the feel of bone. Right eye: vision normal for distant (C + 1·50 D $\frac{2}{20}$) and (presbyopia corrected) for near objects also. The optic disc is of a normal pink tinge, and the retinal arteries and veins are of normal calibre.

After some hesitation the patient consented to be photographed, but she would not listen to operative treatment. In the literature bearing upon tumours of the orbit to which I have had the opportunity of referring I have not been able to find a record of a case similar to this one.

Liverpool.

ON the 3rd inst. Dr. Riddell of Dunsford, near Exeter, committed suicide. The deceased, who died from poisoning by strychnine, had been called upon by the Local Government Board to resign a parish appointment which he held.

CASE OF

TUMOUR OF THE PONS VAROLII AND MEDULLA OBLONGATA.

BY A. MACGREGOR, M.D.,

ASSISTANT-PHYSICIAN TO THE ABERDEEN HOSPITAL FOR SICK CHILDREN.

G. M. —, aged seven years, was admitted into the Aberdeen Hospital for Sick Children on April 21st. His symptoms then were paralysis of the right seventh and sixth cranial nerves, marked deafness on the right side, the eyeballs prominent and strongly drawn to the left, the head drawn towards the right shoulder, with the face turned towards the left, the sterno-mastoid in a state of tonic spasm, headache, and frequent attacks of sickness and vomiting. Temperature from 96° to 97°; the abdominal and thoracic viscera seemed healthy. Specific gravity of urine 1022; otherwise normal.

The patient was one of a family of five. The father died of phthisis; the mother is alive and healthy. Three weeks before admission into the hospital he awoke during the night screaming, and complained of pain in the head. Next morning the facial paralysis was noticed, and frequent attacks of sickness and vomiting followed. For some time previously to this he was considered to be "not well," but no definite symptoms presented themselves.

On April 26th the sickness was distressing, and it was then noted that the right pupil was contracted while the left was dilated, and this continued throughout the course of the illness; occasionally the right dilated slightly, but never to the same extent as the left. The ophthalmoscope showed a haziness and paleness of the right disc and fundus generally, and the vessels were not so full as those of the left fundus, which appeared to be normal. The cornea of the affected eye was insensitive over its entire surface, and its lower half after a time became opaque, and there soon followed a large ulcer, which a few days before death penetrated into the anterior chamber.

About May 1st it was found that the grasping power of the left hand was very much less than that of the right, and that on attempting to walk the patient staggered, with a marked tendency to fall to the right; and it was also noted at this date that the spasm of the right sterno-mastoid had passed off, and that the head had regained its natural position, while the left eye was no longer divergent, but the convergence of the right was even more marked. There was now paresis of the right side of the palate, and the hemiplegia gradually became almost complete. Tactile sensibility was nowhere lost, but pinching up the skin on the point of a needle gave rise to no pain; deeper penetration did. He was unable to distinguish between heat and cold over the surface of the lower limb below the knee; over the other paralysed parts the sensibility to changes of temperature was decidedly diminished. Taste and smell were not affected.

On June 4th the sickness was severe, and the patient could not articulate distinctly. This paralysis of the muscles of articulation passed away next day, but became quite complete on the 6th and remained so till death. On the following day he became unconscious, and the left upper limb passed into a state of spastic rigidity. He remained unconscious until his death, which took place on the morning of the 12th. Previously to this there had been no vomiting for five days, but a few hours before he died he vomited twice, and the temperature rose from 100·5° to 102·6°. During the first week in hospital the temperature was almost constantly 96° and the pulse 116; during the next fortnight the temperature oscillated between 96° and 99°; after this the morning temperature was almost constantly 97°, and the evening temperature ranged between 98° and 100°.

Necropsy.—The brain alone was the seat of any lesion, and the following were the appearances found at the examination made about twelve hours after death:—The dura mater was tightly stretched over what appeared to be a distended brain. The vessels were congested, especially those of the pia mater. The subarachnoid space over the entire vertex was filled with a milky-looking fluid. The olfactory nerves were soft and pulpy, the right more especially. The optic nerves appeared perfectly healthy, as

also did the third and fourth nerves of both sides. The only thing noticeable in the case of the fifth pair was that the sensory part of the right fifth was not so white as that of the left. The sixth nerve of the left side had its natural white appearance, but it seemed smaller than usual; the right sixth was reduced to a couple of small grey gelatinous filaments. The portio mollis of the seventh seemed to be alike on both sides, and to be natural; but while the portio dura on the left side was healthy, on the opposite side this portion of the nerve had the same wasted grey gelatinous appearance as the sixth of the same side. The right glosso-pharyngeal had also more or less of this grey gelatinous appearance. The other nerves did not appear to be altered. There was a marked deformity of the pons and medulla: the right side of both was about a third larger than the left; the enlargement was irregular and nodulated. The chief projection in the pons was towards its lower border, in a direction downwards and backwards. The left side of the pons did not seem to be very much altered. The left olivary body seemed to be a little more prominent than usual. Examined microscopically, the altered nerves were found to be in a state of extensive fatty degeneration. Attached to each olfactory bulb was a quantity of gelatinous material, which was found to be composed of small round cells, very much like those of a sarcoma. The tumour itself was caseous, and composed of a nuinber of small round cells, the greater number of which were shrivelled and broken up.

Aberdeen.

NOTES ON A TYPHOID FEVER OUTBREAK AT FOLKESTONE.

BY CLEMENT E. PRIESTLEY, M.R.C.S., &c.

PERHAPS the particulars of a typhoid outbreak occurring in my practice here may not be without interest to many of the readers of THE LANCET.

On July 1st I was called to visit a girl who had fallen ill in a caravan at the fair then being held in the outskirts of the east end of Folkestone, and found her suffering with premonitory symptoms of typhoid. At the same time I was asked to see several others of the fair people suffering from very similar symptoms. After three days typhoid spots appeared on three of the patients, but as the fair was at an end I could not find out if the others I had seen had typhoid, as they had left the ground. I was, however, given to understand that they recovered without being attacked. Of the three typhoid patients, one was removed to Ashford by her friends before the medical officer had arrived. One was treated at the Sanatorium, and one in a caravan in the middle of the field where the fair had been held. On one side of this field are two small cottages, in one of which a girl of seventeen was attacked with typhoid on July 23rd, and died a few days afterwards. A boy in the same cottage showed symptoms of failing health, but, being removed, recovered without having the disease. A month later I was called to see a lad in the town in whom the malady proved fatal. In August and September I had six other cases of typhoid, all at the eastern part of the town. In each case I have tried to trace the origin of the disease, with the following result. The people of the fair on their way to Folkestone passed through the village of Dymchurch, and, having a difficulty in obtaining sufficient well-water, several drank from a roadside pond, which was brackish to the taste and of a greenish colour. The three persons that had typhoid drank some of this water, as also did the others that suffered from diarrhœa and pyrexia; whilst amongst those of the company who did not have recourse to the pond-water there was no illness. In the case of the girl who died the water supplying the cottage in which she resided is an open spring and close to the tents of the fair people, and could therefore have easily become polluted. Again, the boy had been at the fair constantly and may have contracted the disease there; on the other hand, he was occupied daily packing fish in ice, and was constantly sucking ice. Of the other six cases I could obtain no clue as to the origin of the fever. The inspector or sub-inspector of nuisances inspected their residences, and could not find anything wrong with drains, and only in one instance water-supply; they had not been at or near the fair, and four had not been in contiguity with one another. The milk-supply was investigated, but nothing was discovered. Three patients drank water other than that supplied to the town by the water company; this had been analysed some few months before, and reported as good.

I think these cases go far to prove, first, that typhoid may rise *de novo*, for I cannot hear of any case of typhoid having occurred at Dymchurch; and, secondly, that it is contagious, which is quite contrary to my previous experience. I have seen much typhoid, but have always been able to find and remove the cause, and thus prevent the spread of the disease, even under most unfavourable circumstances.

It is not my province to write with regard to the sanitary condition of Folkestone, but from a year's experience of the state of things existing at the eastern part of it I should say it is unsatisfactory. A mild form of diphtheria is mostly endemic in that quarter, and has been so, I understand, for some time. It may not be out of place to sound a slight note of warning—viz., that a house-to-house inspection of the poorer parts of the town would show a condition of things that, to say the least, must be a cause of surprise when one contemplates how very near we may be to a cholera epidemic. On the other hand, the western portion cannot be spoken too highly of.

Folkestone.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prœmium.

GUY'S HOSPITAL.

A CASE OF LOCOMOTOR ATAXY WITH SEVERAL UNUSUAL SYMPTOMS; REMARKS.

(Under the care of Dr. HALE WHITE.)

THERE are few diseases which present such a multiplicity of symptoms as are found in locomotor ataxy, of which the following case is an example. The prognosis is very unfavourable, but the course of the disease may be spread over a long period (even thirty years according to Bristowe), the patient, however, making frequent calls on the physician for relief of symptoms. Although, as Dr. Hale White observes in his remarks, death is generally due to intercurrent disease, it may also be caused by implication of the muscles of deglutition, paralysis of the laryngeal muscles, renal disease secondary to vesical mischief, or even to bed-sores. We refer our readers to the remarks appended to the case.

Alfred P——, aged fifty, was admitted on June 10th, 1886. He was in Philip ward, under Dr. Fagge, in 1883. An old report states: "He has been the subject of chronic rheumatic pains for many years. Three or four years ago he suffered from indigestion; three months ago he had a sharp attack of pain in the stomach, lasting all day, and accompanied by vomiting. These attacks have become more sharp and frequent lately. The pupils are unequal, the right being larger than the left. They do not react to light or accommodation. He can stand with his eyes shut; he has paralysis of the right external rectus and diplopia; both discs show a white margin and venous pulsation. The patellar reflex is absent. The superficial reflexes are normal. Sensation: Occasional numbness of legs and arms. He has shooting pains starting in the toes and running up the legs. He has girdle pains at the lower part of the thorax, the ring being about four inches across. He has numbness over this area and upwards to the shoulders behind, and down the extensor surfaces on both sides as far as the hands; he has also numbness of the face and head. Twenty-one days after admission he suddenly had transitory pains of the right upper limb. The stomach had sometimes to be washed out. He can turn and walk easily along a chalked line." The old report, to which all the above refers, is headed "Early Tabes Dorsalis, with Gastric Crises." He has been getting worse since; has had much difficulty in breathing; he went to St. Bartholomew's Hospital last January, stayed there three months, and was tracheotomised for this trouble.

State on admission.—The abductors of the vocal cords are quite paralysed, and they are so close together that they leave a median chink no wider than the thickness of a sheet of note paper. They appear healthy, but are quite immovable when he speaks or breathes. He wears an indiarubber tracheotomy tube with an opening on its upper surface. He speaks, very hoarsely and indistinctly, by putting his finger over the tube. His hearing is preternaturally acute. His sight is bad; he wears convex glasses; has conjunctivitis in both eyes; the right pupil is the larger; pupils do not react to light or accommodation; there is no strabismus, but there is complete ptosis of the right eye, and there is hemiatrophy of both discs. He cannot stand with his eyes shut, and walks with a slightly ataxic gait. His muscles are very little wasted; there is no rigidity. Tendon reflexes all absent, superficial ones diminished. He very rarely gets gastric crises now. The anæsthesia, numbness, and girdle and lightning pains remain as before. All his joints are healthy. His tongue is normal. Only two teeth are left in the upper and one in the lower jaw; some of the teeth have been extracted, others have fallen out, and one or two have broken off near the root; those in the mouth now are not decayed, but are quite loose. The alveolar processes of the jaws are quite atrophied. He has a sensation as if he always had food in his mouth. Bowels irregular. Occasional catheterisation is required. No sexual disturbance. The patient seems to be deficient in power of smell.

Remarks by Dr. HALE WHITE.—It will be noticed that the diagnosis of tabes dorsalis was made, when the patient was last in the hospital, from three symptoms—namely, (1) the pains, (2) the abolition of reflexes, and (3) the gastric crises. There was at that time no locomotor ataxy, yet the diagnosis was pretty certain from these three symptoms, which are all of them usually present early, generally before the ataxy. Locomotor ataxy is a bad name, for it is only the name of a symptom. We may have ataxy due to (1) cerebral disease, (2) cerebellar disease, (3) spinal cord disease, and (4) peripheral nerve disease; and for each of these it may be due to disturbance of (1) sensory function, (2) motor function, and (3) both combined. So we must insist that ataxy is only a symptom, and therefore not a diagnosis, any more than is albuminuria or jaundice. From the position of the lesion we can explain some of the above symptoms. The initial sclerosis is either in the posterior grey horn, or in that part of the column of Burdach traversed by the inner division of the posterior roots as they reach the level of entry into the grey substance. It is distinct from the secondary degenerations which accompany it. The affections of the columns of Goll and Clarke and the cerebellar tract are truly systemic; that of the middle area of the column of Burdach probably is not; whilst that of the root zones certainly is not. The reasons for looking upon the degeneration of the column of Goll in tabes as a true secondary degeneration are that when the lesion in the primary field is in the lower lumbar or sacral region, the degeneration of Goll's column is limited to its postero-internal border; when the primary lesion is in the upper lumbar or lower dorsal region, the rest of Goll's column is affected; and when the primary lesion is in the upper dorsal or lower cervical region, the comma-shaped area of Burdach's column is affected. The position and amount of sclerosis in the above-mentioned areas vary proportionately to the position and amount of the motor ataxy. Hence it is seen that we are able to determine the position of the lesion when the case shows motor ataxy. By an analogous process of reasoning we are able to say that when the case presents static ataxy the cerebellar tract will be involved. Degeneration of these tracts just mentioned is never connected with any other symptoms than motor and static ataxy. The degeneration of Clarke's column is probably in some way connected with static ataxy. By a similar method of careful comparison of symptoms during life with pathological appearances after death, it has been found that an area with its base at the border of the cord for a short distance, one side along the inner border of the posterior root, and a third side joining the other two, is always diseased in cases in which there are severe pains, hyperæsthesia, or analgesia; hence we say that this lesion is the cause of these symptoms. The affection of the external root zones causes abolition of the tendon reflexes. Thus we are able to localise the cause of four of this patient's symptoms—viz., (1) the motor ataxy, (2) the static ataxy, (3) the sensory disturbances, and (4) the abolition of reflexes. The other symptoms are so various and so difficult of pathological localisation that some hold that the disease is a diffuse inflammation affecting the nervous system in different parts. Three views are held as to the pathology of the changes in the cord—1. The sclerosis begins in the nerve bundles (primary neuritis). 2. It begins in the connective tissue (interstitial neuritis). 3. It begins in the vessels (vascular neuritis). Which of these is true we cannot yet say; the last has fewest adherents. With regard to the other symptoms: 1. Gastric crises. In this patient, as usual, they are an early symptom, disappearing later on. 2. Laryngeal crises. These may or may not be followed by laryngeal paralysis; whether or not this patient ever had any laryngeal crises is not quite certain. The laryngeal paralysis is a very rare symptom; it is generally a paralysis of the abductors, as here, and is dangerous as necessitating tracheotomy. 3. Paralysis of ocular muscles. This symptom was also present. 4. Eye symptoms are often present; they are mydriasis, myosis, the Argyll-Robertson symptom, optic atrophy, colour blindness, restricted field of vision, hemiopia, loss of accommodation, and diplopia. This patient presented several of these; he was tested for all. 5. Perversion of hearing. Deafness is common; in this case great acuteness of hearing, a rare symptom, was present. 6. Perversion of tastes—a rare group; perhaps the sensation of food in the mouth experienced by this patient should be referred to it. Hemiatrophy of the tongue is described. 7. Perversion of smell—a rare symptom—was present in this case. 8. Transitory paralysis of various muscles is also rare. This patient had transitory paralysis of his right arm. 9. Bladder disturbance. This is rare; this patient appeared to have some vesical paralysis. 10. Trophic symptoms. These are usually in the joints; but it is noteworthy that this patient has lost many of his teeth, for that has been described by several French authors as a trophic symptom. It has been suggested that the edentulous cases are generally present with laryngeal crises. It was so here. Perforating ulcers and changes in the nails have been described in tabes. 11. Sexual disturbances: firstly, an excess of virile power; later, paresis of it. This patient does not present either of these. 12. Mental symptoms are common, but this patient did not show any; when they appear the motor ataxy may disappear. Many of the above symptoms are so rare that it is very doubtful whether their occurrence in locomotor ataxy is more than a coincidence. Dr. White also refers to the etiology of the disease, and its connexion with syphilis, pointing out that 90 per cent. of the cases of locomotor paralysis have had syphilis. He recommends iodide of potassium in large doses, and gives as a prognosis death sooner or later from intercurrent disease, possibly of the lungs.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

TWO CASES OF CLEFT PALATE, AND ONE OF ACUTE PERIOSTITIS OF THE FEMUR; REMARKS.

(Under the care of Mr. EDMUND OWEN.)

THE notes of the following cases have been furnished by Dr. Penrose.

CASE 1. *Cleft Palate.*—Rosa W——, aged five years and four months, was admitted on July 26th for a cleft of the soft and the posterior part of the hard palate. Her mother gave a graphic account of how, between the second and third months of pregnancy, she was shocked by the sight of "a man who had a hare lip, and who spoke funnily." She mentioned the occurrence to her husband. (This is recorded rather as a matter of history than as of scientific import.) After a few days' stay in the ward, so that she might become accustomed to her strange surroundings, and learn obedience to sister and nurses, the child was brought into the theatre for operation. Chloroform was administered on a piece of lint, and a Smith's gag was introduced. The edges of the cleft were pared, the mucoperiosteum was detached from the under surface of the hard palate by the use of curved raspatories, and the flaps were approximated and secured by fine sutures introduced by a Marion Sims' tubular needle, furnished with a reel of silver wire at the end of the handle. All tension of the united flaps of the velum was then eased by a free incision made through it on either side of and parallel with the line of suture, and the child was dis-

charged on the fourteenth day. When seen two months after the operation, the palate was quite sound, several of the sutures were remaining, and the voice and speech were steadily improving.

CASE 2. *Cleft Palate.*—Betsy G——, aged seven years and three months, was admitted from Chesterfield on July 14th with a complete and wide cleft of the hard and soft palate. She had been operated on fifteen months previously, but with no success. The muco-periosteum having been detached from the palatine processes, and the soft palate having been freely disconnected from beneath the horizontal plate of the palate bone by the use of curved scissors, the pared edges of the cleft were sutured as described in the preceding case, the tension being relieved by exceedingly free lateral incisions. She was discharged on Aug. 19th. On October 14th Dr. Macdougall wrote that the only spot where union was not perfect was just in front of the soft palate. This aperture will probably grow steadily smaller; if not, it can be easily closed at any time. The child's father writes that her speech is "altogether improved."

Remarks by Mr. OWEN.—The operation for cleft palate has been much simplified of late years by the use of chloroform and of the tubular needle with the endless wire, and by the introduction of Smith's gag. The relief of the dragging of the tensor and levator palati, too, is much more easily accomplished by the simple transfixion of the halves of the soft palate, and by making an incision through it, forwards and backwards, by a tenotomy knife. My experience is that the success of the operation depends very much on the boldness with which these lateral incisions are made; and freely as I make them now, I have had no experience of sloughing of the parts; fortunately their vascular supply is extremely free. The children are kept very little in bed, but they are carefully watched lest they introduce their fingers or solid food into the mouth.

CASE 3. *Acute Periostitis of Femur.*—Agnes S——, aged six years and four months, was admitted on July 28th. On June 15th she had to be taken out of school because she was sick; she walked lame, and complained of pain at the right knee. At night she was very feverish, but there was no delirium. She was thought to be suffering from rheumatic fever, and the occurrence of swelling about the knee a few days later seemed to offer confirmation of that diagnosis. She continued very ill for three weeks, the urine being thick. Immediately on her admission into the hospital she was put under chloroform, so that the tender limb might be thoroughly examined. A fluctuating swelling was found over the lower two-thirds of the thigh, and the house-surgeon (Dr. Hinds) opened it by Hilton's method, attacking it through the interval between the ilio-tibial band of the fascia lata and the tendon of the biceps. A large quantity of brownish fluid escaped, and on introducing the finger a surface of the femur near the linea aspera was found denuded of periosteum; a counter opening was made through the brawny integuments on the inner side of the limb, and the wound was thoroughly drained. The cavity was irrigated with an antiseptic solution, surrounded with mercuric dressing, and firmly bandaged, the limb being fixed on a splint. After the operation the temperature never reached 100° F., and the child was discharged cured on the twenty-eighth day.

Remarks by Mr. OWEN.—This is one of those many cases in which periostitis has been mistaken for articular rheumatism. The suddenness of the onset of the symptoms, the redness, swelling, and tenderness of the limb, the high temperature, and the great constitutional distress, all seemed to point to rheumatism. The diagnosis could have been made by the fact of the swelling being not *in* the joint, by the existence of central enlargement and tenderness in the *shaft* of the bone, and subsequently, if that were necessary, by the temperature remaining uninfluenced by the administration of salicylic acid. To the comparative mildness of the periostitis must be attributed the child's happy escape from necrosis, consecutive purulent arthritis and pyæmia—those frequent consequences of acute periostitis in childhood.

PROPOSED ITALIAN HOSPITAL.—The fourth annual ball in aid of a fund started for the purpose of founding a hospital for the benefit of Italians in London, was held on the 1st inst., and proved very successful. There is at present a small Italian hospital in Queen-square, Bloomsbury, but this has long since outgrown [illegible] on it, and it is in contemplation [illegible]

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Tumours of Palate.—Researches concerning Pasteur's Prophylactic.—Flagellated Organisms in the Blood.—Epithelioma of Larynx.—Disseminated Fibrosis of Lungs.—Addison's Disease associated with Cystic Condition of Pineal Body.—Included Ovum.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. S. Bristowe, F.R.S., President, in the chair. Mr. F. Treves and Dr. Angel Money were nominated as auditors of the Society's accounts.

Mr. STEPHEN PAGET read a supplementary note on a specimen of Tumour of the Palate, exhibited to the Society on Nov. 2nd, 1886. The chief masses of the tumour were epithelial. In a second similar tumour removed by Mr. Walsham there were identical masses of epithelium. In both there were cell-nests, glandular structures, and intervening tracts of embryonic tissue. The existence of cell-nests in tumours which were evidently innocent was a point of great interest. In their history and course these tumours of the palate resembled those occurring in the parotid region, and were probably examples of included embryonic vestiges.

Dr. HIME read a paper on Experimental Researches concerning Pasteur's Prophylactic, which will be found on another page.—Mr. VICTOR HORSLEY said that the pathognomonic appearances of rabies as described by the French school were in the stomach, which was congested in 70 per cent. of the cases, and hæmorrhages of varying size were found in the submucous tissues. The contents of the stomach were very important; foreign bodies of all kinds in large quantity and variety indicated a perverted appetite. Then about the root of the tongue and larynx, with but few exceptions (5 per cent.), there were signs of active congestion, whether due to the mode of death or not he could not say. In the central nervous system there was nothing definite. The lungs showed signs of catarrhal pneumonia, which might be due to secondary consequences. These signs were seen in the rabbit and dog. The small intestines of the rabbit and dog were empty except for straw-coloured serum, and the large bowel contained fæces, and often there was melæna.—Dr. HIME said that the stomach need contain no miscellaneous articles in rabies, and dogs may die with a variety of articles in the stomach without having had rabies. In true rabies the stomach may be absolutely empty; especially is this the case in the exceedingly violent form of rabies with marked paralytic symptoms.—With these statements Mr. HORSLEY also agreed.

Mr. CROOKSHANK showed specimens of Flagellated Organisms in the Blood of Healthy and Diseased Animals. There was an epidemic disease that prevailed at long intervals in horses, camels, and mules in India; it was a blood disease called "surra," and supposed at one time to be dependent on the presence of a kind of spirillum—"equine spirillum fever." The organism had very distinctive features, was of fusiform shape, with a longitudinal delicate membrane and flagellum at either end. Such an organism has been discovered in the blood of the calf. The hæmatomonas of fish was similar. But Leuckart's description of trichomonas would probably include the organism found in Indian rats by Timothy Lewis. Such organisms had been discovered by Mr. Crookshank in apparently healthy London sewer rats, whose blood teemed with them. It was difficult to be sure that the organisms were pathogenic, even in the disease called "surra."

Dr. S. WEST showed an extensive Epithelioma of the Larynx, taken from a man aged forty-three, in whom aphonia and dyspnœa of purely laryngeal origin, that necessitated tracheotomy, were the first symptoms. The left vocal cord was found to be fixed, and there was a slough on it. Anti-syphilitic remedies were tried without effect. Mr. Butlin saw the case and advised that extirpation of the larynx should not be practised. The ulceration extended from the base of the epiglottis to the first cartilage of the trachea. The thyroid and arytenoid cartilages were extensively destroyed. There was no very obvious glandular enlargement.

Dr. HADDEN showed the lungs of a man aged sixty, a mason. The man died soon after admission into the hospital from the effects of an injury. No history could be obtained. Numerous small white dots, surrounded by a ring of pig-

ment, were scattered all over the surface of the lung. These dots were simply thickenings of the pleura, and the pigmented areas corresponded to small hard fibrous nodules just beneath the pleura. There was a large hard pigmented mass at the apex of the right lung, and some thickened pleura over it. A small calcareous nodule was found in the centre of the mass. The nodules and the large mass were made up of dense fibrous tissue with pigment. There was no excavation or caseation. Bacilli were not discovered. The bronchial glands were pigmented and calcareous. The lung tissue generally was crepitant, not emphysematous. The author thought it probable that the case was one of masons' phthisis, although the change was not diffuse as in those cases generally. Syphilis might have been the cause, but there were several facts against this.—Dr. BRISTOWE considered that his specimen, to which Dr. Hadden had alluded, was one of obsolescent miliary tubercles. — Dr. PYE-SMITH referred to certain pleural nodules surrounded by rings of pigment, and which were miliary tubercles.—Dr. EWART said that Dr. Hadden's specimen looked familiar to him. The pleural nodules probably originated in connexion with irritation of the lymphatics; he did not think tuberculosis of that violence would affect merely the surface of the lung.—Dr. PERCY KIDD thought that the fibromatous nodules might originate in the lymphatic stomata.—Dr. S. COUPLAND supported the view of the two previous speakers. In one case that he had examined for Dr. Greenhow, the nodular growths in the pleura appeared to be formed in connexion with lymphatics.—Dr. HADDEN did not object to the view that the pleural nodules originated at the site of lymphatic stomata, but there were lesions also scattered throughout the lungs.

Mr. A. Q. SILCOCK showed two specimens of Addison's Suprarenal Capsules associated with Cystic Pineal Glands. The first case was a man, aged thirty-six, in whom emaciation and vomiting were symptoms. The adrenal bodies showed changes typical of Addison's disease. There was no tubercle anywhere else in the body, and no bacilli were found in the caseous matter of the suprarenal. There was no obvious pigmentation of the skin. The second case was that of a woman who was "suckling" just before death. The pineal body was cystic, and of the size of a small cherry. There was deep pigmentation of the inner parts of the thighs and mammary areolæ. There were constant vomiting and great emaciation; but as Bright's disease also coexisted, little stress could be laid on the former symptom. Numerous caseous foci were scattered through the suprarenal bodies, and there was general fibrosis; the arteries were greatly thickened and obliterated in places. Sir W. Gull had noticed the similarity of structure between the pituitary body and the structure of the adrenals, and had observed such a cystic change. Some recent observations of Mr. Baldwin Spencer seemed to show that the pineal gland was homological with the vertex eye of lacertilians.

Dr. SEYMOUR TAYLOR showed a specimen of Included Ovum taken from a male infant aged eleven months. The tumour was situate behind the stomach, in the median line, and lying on the first and second lumbar vertebræ. It was of the size of a duck's egg. It showed a rudimentary vertebral column and coccyx, with spinal cord and meninges; also a primitive intestinal canal. There was also a mass of dense fat. The external surface of the ovum was coated with skin. There were rudimentary limbs and pelvis. A layer of vernix caseosa was detected. The features found would indicate the developmental condition of the fœtus at the tenth or eleventh week.—Dr. WALTER GRIFFITHS thought the specimen was acardiacous rather than anencephalous. The further degree of development depended on the fact that it was contained in a host that lived for nearly a year.—Mr. STEPHEN PAGET referred to a case of fœtal tumour growing from the hard palate, published in THE LANCET, 1881, as showing that the condition described was not necessarily due to invagination.—Dr. PYE-SMITH considered that Mr. Paget's objection was not a conclusive argument against invagination.

The following card specimens were shown:—Mr. Sydney Jones: (1) Malformation of Hand: (2) Large Calculus with hairpin as nucleus. Mr. E. H. Fenwick: Finger-shaped Calculus. Dr. Herringham and Mr. D'Arcy Power: Sarcoma of Brain and Cord. Mr. Shattock: Microphthalmos. Dr. H. Sainsbury: Occlusion of Coronary Arteries in Angina Pectoris. Dr. Hebb: Tuberculosis of Uterus. Dr. Hadden: (1) Cirrhosis of Pancreas in Diabetes; (2) Tubercular Ulceration of Trachea; (3) Carcinoma of Cæcum with extreme narrowing. Dr. Pasteur: (1) Lung in Chronic Pleurisy; (2) Organs from a case of Addison's Disease. Dr. G. N. Pitt: (1) Multiple Erosions of Stomach following a Burn; (2) Ascending Nephritis leading to a local scarring of Kidneys. Mr. Reginald Harrison: Urinary Organs from a case of Bilharzia Hæmatobia. Mr. T. Smith: Hypertrophy of Mammary Gland, with adenomata.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on December 1st, Dr. J. B. Potter, President, in the chair.

The following specimens were shown:—Mr. Alban Doran: A Dissection of the Muscles of the Female Pelvis. Dr. Phillips: Conjoined Twins; Dicephalous Monster delivered with one pain without assistance. Mr. Malcolm showed for Mr. J. Knowsley Thornton a pair of Diseased Ovaries.

On Mercurialism in Lying-in Women undergoing Sublimate Irrigation, by Dr. W. R. DAKIN, B.S.—The author gave a list of recorded deaths from mercurialism in lying-in patients, with an epitome in each case of the post-mortem appearances. He mentioned Keller's recognition of mercury in the urine of patients douched with sublimate solution, confirmed by his own experiments. Having noticed the contra-indications to its use, he detailed the method employed at the General Lying-in Hospital, and examined the conditions affecting susceptibility to the poison, including von Herff's experiments. The symptoms of poisoning were given in detail in the cases observed. He narrated two cases, one of the milder form of poisoning and one fatal, in which the post-mortem appearances and histology of the kidneys were given, and made a comparison of results obtained as regards temperature, rate of involution, and duration of lochia under different modes of using the solution. The precautions to be observed and the most successful method of use were then indicated, the opinions of continental physicians quoted, and the treatment which proved most useful pointed out. He gave a table of affected cases under his observation, showing the symptoms and their respective dates of appearance, with a list of authors referred to in the course of the paper.—Dr. BOXALL thought that the first fatal case related by Dr. Dakin was due to shock from the sudden passage of foreign material into the blood stream through the uterine sinuses. He had seen such a fatality after an intra-uterine injection of carbolic acid. As one of Dr Dakin's more immediate predecessors at the General Lying-in Hospital, he had an excellent opportunity of observing the results obtained by carbolic acid and permanganate of potash compared with corrosive sublimate as an antiseptic agent. Dr. Boxall showed a table representing the morbility among all the patients admitted to the hospital during sixteen months. Nothing but sublimate irrigation (1 in 2000) was used during the latter half of the time, and the morbility was reduced in a marked degree. Among 240 patients delivered during the sublimate era, three cases of slight mercurialism occurred; while pyæmia, septicæmia, and local pelvic mischief were almost entirely eliminated.—Dr. DAKIN had reported ten cases of mercurialism after 165 deliveries, but the symptoms were very slight, and a solution of 1 in 1000 is at present employed immediately after labour.—Dr. BOXALL thought that sublimate solution deteriorated, owing to the alkalinity of London water, and he advised a concentrated preparation from which to make the solution for immediate use, with the addition of dilute hydrochloric acid in the proportion of four drachms to each ounce of solid sublimate.—Dr. JOHN PHILLIPS thought that the question of intra-uterine injections was still *sub judice*. As regards vaginal injections, if there were no lacerations the use of the sublimate might be safe, not otherwise. He used a 1 in 2000 solution to dip the hands in before examinations, and was accustomed to add enough litmus to colour it pale purple.—Dr. MATTHEWS DUNCAN recognised the supreme importance of the subject now brought before the Society in a valuable contribution. He remembered the wonderful diminution of morbility in the Edinburgh Maternity Hospital when antiseptic treatment by carbolic acid was introduced there. Now he had no maternity hospital unfortunately, but only the experience acquired in home and consulting practice. Nothing in the [illegible] midwifery could show such [illegible] the import-

ance of details was shown by Dr. Boxall's table of the results in the York-road Hospital—a gradual and very large diminution of morbility, as the antiseptic was changed from Condy's fluid to carbolic acid and from that to corrosive sublimate, from first to last a diminution of more than 30 per cent. The paper showed the dangers of mercurial antiseptics, and he should not be satisfied with care after the mercurial poisoning began. Such care might be too late. In consequence he confined the use of the sublimate to one or an occasional application, using carbolic acid for the continuous antiseptic washings. He had not seen hydrargyrismus when the antiseptic was used in this way. Great care must be taken to leave no part of the solution in the patient. This is especially necessary when what has been called ballooning of the vagina occurred, a state due rather to intra-abdominal pressure than any condition of the perineum.—Dr. PARAMORE advocated the use of alcohol as an antiseptic injection during and after labour.—Dr. GRAILY HEWITT thought that the practice of midwifery in private and in a lying-in hospital could not be looked upon as identical so far as the frequent use of antiseptic injections was concerned. He was anxious to insist on this, because if it went about that the internal injection of a dangerous antiseptic such as corrosive sublimate was in the opinion of this Society essential to the safety of the lying-in patient, it would be the cause of infinite mischief. No doubt in a lying-in hospital extreme precaution was justifiable, but in private practice less dangerous materials could be employed, and frequent use of injections could not be held to be necessary.—Dr. ROGERS had seen sudden death follow an intra-uterine injection of iodine in a case of fibroid of the uterus with metrorrhagia. He now always uses dilute iodine irrigations, and has never seen or known any bad result.—Dr. CHAMPNEYS feared the present discussion might hamper those who rightly might wish to use sublimate irrigations in suitable cases. Private practice and hospital practice differed in one respect. In both the patient required protection from infection by the accoucheur and nurse, but the latter also required protection from other patients. We had to balance the risk of sepsis against the risk of mercurialism, and he unhesitatingly embraced the latter. During the five years in which Dr. John Williams and he had charge of the General Lying-in Hospital their mortality was but 7 per 1000, and in the face of such results he cheerfully accepted the responsibility of the risk of mercurialism by routine post-partum irrigation with sublimate. In private practice he reserved this for cases specially liable to infection—cases of operation—in which he did not hesitate to wash out the uterus (if entered by the hand) or vagina with corrosive sublimate (1 in 1000 or 2000). He did not usually repeat the sublimate, preferring to leave one of Ehrendorfer's iodoform bougies in the uterus. In simple cases in private he used Condy.—Dr. W. Duncan, Dr. Fowler, and the President took part in the discussion, and Dr. Dakin replied.

MEDICAL OFFICERS OF HEALTH SOCIETY.

School Lighting.—Sanitary Registration of Dwellings.

A MEETING of this Society was held at the Scottish Corporation Hall, Crane-court, Fleet-street, the President, Dr. Alfred Hill, in the chair.

Dr. WILLOUGHBY read a paper on School Lighting, of which the following is an abstract:—In introducing the subject of school lighting, Dr. Willoughby referred to the fact that, unlike hyperopia, which was always congenital, myopia was the direct result of reading or otherwise exerting the eyes under unfavourable conditions, though when once acquired it showed a tendency to hereditary transmission; that, unknown among uncivilised races, it prevailed among the civilised in direct ratio to the amount of "schooling," and in schools and universities progressively from the younger to the senior students. Faulty postures and other circumstances aided in its production or aggravation, but these again were greatly dependent on insufficient lighting. From the ease with which one reads in the open air when the sky is overcast, he argued that the perfection of illumination was to be found in a full uniform *shadowless* light; that while under all circumstances one had to avoid the projection of the shadow of the head on the work, and of that of the hand on the written word, one should [illegible] natural illumination guard also [illegible] the sun, [illegible] drying of the conjunctiva by the heat given off from gas or oil lamps, which, moreover, deteriorate the air of schools, in which the cubic space was almost always grossly insufficient, 250 cubic feet per head being absolutely necessary, though even the London School Board allowed only 130 for each child, and the code sanctioned 80! In all these respects the electric "glowlight" presented great advantages. In natural illumination the chief points to be considered were the aspect of the windows, their position as regards the scholars, and the proportion between their area and that of the room; the relation of neighbouring buildings, the "angular aperture," and the angle of incidence of the light as affecting its intensity. Dr. Willoughby maintained that so long as the light from the left was the stronger, so that the shadow of the hand did not fall on the writing, the objections urged against "cross-lighting" were imaginary, and that while the main source of the light should always be on the left, it might with great advantage be supplemented by lights of lesser intensity from other sides, the total illumination being thus increased. Blinds being open to several objections, he condemned south windows except when ground or dimmed and used as subsidiary sources, preferring north, east, and west windows, which did not admit direct sunshine. In wide rooms the rows of desks on either side should face in opposite directions, so that the nearer and therefore the stronger light, whether from the east or west, should always come from the left. These principles were also applicable to artificial lighting, for which he advocated the use wherever possible of the electric light, on the ground of its greater intensity and the absence of heat and of the products of combustion. Shades acting also as reflectors he considered very preferable to semi-opaque globes, which involved great loss of light. The two points to be observed in the arrangement of the lights were the avoidance of shadows and of the direct incidence of the light on the eyes. Where gas must be employed he recommended the use of naphthaline, the so-called albo-carbon, by which the illumination could be increased tenfold. But whatever the illuminant, he would suggest as the best arrangement one or more large lights on the ceiling, and smaller lights with shades, as used in billiard-rooms, over the desks. The number of these which would be required could only be determined by experience, but he strongly urged a trial of this arrangement, which he believed had never been attempted.

Mr. MARK H. JUDGE followed with a paper on the Sanitary Registration of Buildings Bill. Sanitation is, he said, in the air, though the public mind may be slow to realise the truth of the adage that "cleanliness is next to godliness," and that in reality sanitation is the science of cleanliness, and a science which becomes of importance in proportion to the density of the population. With the growth of population there has grown a sense of the need of giving more attention to the science of cleanliness, and at present we have a mass of sanitary legislation which, while failing to secure satisfactory conditions with regard to the removal of refuse from our towns, at the same time gives greater powers to local authorities than they have hitherto exercised. As an instance of the great powers conferred by Parliament on the local authorities with regard to sanitary matters, he had only to refer to the Metropolis Local Management Act of 1855, under which Act the London vestries have absolute authority to regulate the sanitary arrangements of every house or building, whether erected before or subsequent to the passing of the Act, provided there be a public sewer within 100 ft. of such house or building. These powers were, and are to this day, greater than public opinion would tolerate the exercise of, and therefore to a large extent the Acts under which they have been granted have been dead letters. According to the 73rd Section of the Metropolis Local Management Act, the vestries of London are made practically responsible for the public sewers and house drains, as well as for the sanitary arrangements generally. Similar powers are conferred upon local Boards of Health under the Act of 1875, but modified by the supervision of the Local Government Board. In spite of the existence of these great powers, the fact remains that our towns are in a lamentable state so far as the sanitation of our dwellings is concerned. That the present law has failed to secure reasonably healthy dwellings in our large towns was never more forcibly stated than last year, when the Government introduced the Housing of the Working Classes Bill, which provided that "in any contract for letting for human habitation an unfurnished house, or part of an unfurnished house, there shall be implied a condition that the house is in all respects

reasonably fit for such habitation; and in the event of a breach of such condition as above mentioned, in the case either of a furnished or unfurnished house, or any part thereof, any inmate of such house who suffers any loss or injury to health or otherwise in consequence of such breach shall be entitled to recover damages from the person responsible for such breach." The opposition this proposal met with was, however, so great that when the Act became law this bold attempt to prevent the adulteration of houses had dwindled down to the following:—"In any contract made after the passing of this Act for letting for habitation by persons of the working classes a house or part of a house, there shall be implied a condition that the house is at the commencement of the holding in all respects reasonably fit for human habitation. In this section the expression 'letting for habitation by persons of the working classes' means the letting for habitation of a house or part of a house at a rent not exceeding in England the sum named as the limit for the composition of rates by Section 3 of the Poor-rate Assessment and Collection Act, 1869, and in Scotland or Ireland £4." This would seem to suggest that except when let to persons of the "working classes," houses may or may not be reasonably fit for human habitation, and thus it is more than ever necessary that something should be done to remedy the existing state of things. The Sanitary Registration of Buildings Bill is a legislative attempt to protect the community against unsanitary dwellings. It is to be brought before the House of Commons early next session by Dr. R. Farquharson, M.P., and may be briefly described as an effort to secure the maximum advantage with the minimum of officialism. The principle on which the Bill is based is the same as that on which the Vaccination Acts are administered viz., the enforcement of a State regulation for the public benefit, while at the same time leaving individual citizens freedom in the matter of carrying out the same. It is not proposed that owners and occupiers of property should be relieved of their proper responsibility, though such inspection and supervision might for the moment greatly improve the sanitary condition of large towns. The provisions of the Sanitary Registration of Buildings Bill are:—1. That the Act shall come into operation in January, 1888, in all towns in England of 50,000 inhabitants and upwards, and in such other districts in the United Kingdom as may choose to adopt it. 2. The authorities entrusted with carrying out the Act are the same as those charged with the administration of the Public Health Acts. 3. Each authority shall appoint a sanitary registrar, whose duty it shall be to issue certificate forms for buildings, such forms to be returned in the same way as the vaccination papers issued on registration of births. 4. These certificates will declare that the buildings to which they refer are in a satisfactory sanitary condition, and shall be signed or sealed by specified competent persons or by corporations. 5. Where the owner or occupier wishes it, he may call in the services of the surveyor or engineer to the local authority to certify his house, but in that case he is to pay a fee to the local authority for the services rendered. 6. After January, 1889, it is to be unlawful for any dwelling-house, school, hotel, hospital, or other building to be occupied unless and until a certificate as described is deposited with the local authority. 7. A penalty is provided in case of the issue of a false certificate, and the wilful issue of a false certificate is made a misdemeanor; penalties are also provided for letting or occupying a house without a certificate. All whose opinions are worth consideration recognise the fact that serious imperfections exist in the sanitary arrangements of dwelling-houses, and are alike earnest in their desire to amend them. All are not, however, agreed as to the best means to be adopted to bring about the sanitary reform desired. Some would make it the business of the State to design and regulate the sanitary arrangements of every dwelling-house; others think that the State should have no right to inquire into the sanitary condition of any private property, and that it should in no way interfere with those who choose to reside in dwellings of the flimsiest description. Mr. Judge thought that in this, as in all other matters, the rule of liberty would be found the best preserver of the public well-being, which, correctly understood, includes the well-being of the individual. Where drains and sewers are public property, the responsibility for their proper maintenance admittedly rests in the State, or its representative, the local authority of the district. Any citizen who may be injured in consequence of the unsanitary condition of such public drains or sewers should, he thought, have right of action against any authority through whose neglect the unsanitary condition is proved to have been caused. On the same ground he would urge that in all cases of private drains and sanitary arrangements the responsibility for their proper maintenance should rest in the owner (or occupier when he stands in the place of the owner), and that the public authority should only have right of action in so far as the condition of the property may be directly injurious to the public health. That the sanitary arrangements of dwelling-houses should be of one uniform pattern, or that the internal economy of our houses ought to be submitted to the censorship of a public official, cannot be desirable. He did not desire to see the law with regard to compulsory sanitation increased—i.e., that the local authorities should have greater powers given them—but he would gladly welcome reform which would amend and strengthen existing law. At present the powers which the local authorities might exercise are considerably greater than any local board does exercise with any consistency, and it is this want of consistency in the enforcement of the Public Health Acts which has made them so inoperative. Too much has been attempted and too little done. Regulations have been made and builders have been told that a variety of things must be attended to, but in too many cases local boards and their officials have been content with framing regulations and giving orders. They have failed in the essential thing—viz., in seeing that builders and others obey. Mr. Judge would strengthen the law by minimising its demands to essentials, and by insisting on its absolute enforcement; he would increase the responsibility of the individual; but in so far as the public authorities pretend to interfere, he would make it a real interference, and in every case where the law was not complied with there should be some punishment meted out to those responsible for the breach. The Sanitary Registration of Buildings Bill does not, however, make any attempt in the direction of the very important work of amending and modifying existing sanitary laws. The Bill only deals with the one question of sanitary registration, and asks that it should not be lawful for any building to be occupied until it is certified as reasonably fit for habitation.

The Council presented a report on a communication recently addressed by the Commissioner of Police to metropolitan sanitary authorities on the subject of Disinfection of Cabs, stating that he was advised that the sanitary inspector is the proper authority for disinfecting cabs which may have conveyed a person suffering from contagious or infectious disease, and asking for information on the subject, and also if a certificate could be given to the driver that his cab was disinfected, so that he may be able to satisfy the police when inquiry is made of him. The Council reported that although the risk of cab infection is very slight, owing to the general use of ambulances, yet that it is very desirable that the sanitary authorities should, when occasion requires it, disinfect cabs free of charge, and that a certificate, the form of which was suggested in the report, should be given to the cab-driver.

The Council also presented a statement on a recent report of the General Purposes Committee of the Metropolitan Asylums Board on the subject of contract with metropolitan sanitary authorities for the reception into the Board's hospitals of persons suffering from infectious disease, and who are not paupers. After reviewing the various Acts and regulations on the subject, the Council reported that in the interest of public health every possible facility should be afforded for admission to the hospitals of the infectious sick; and that as no attempt has been made to define "non-pauper" from other cases, presumably owing to the difficulty attending any such definition, and as dangerous delays would inevitably result from conflict of opinion between Poor-law and sanitary authorities as to the status of candidates for admission to the hospitals, the wiser and better course would be some arrangement whereby these rate-supported hospitals should be freely open without payment to all classes of the community without distinction; that orders for admission should be given by medical officers of health as well as by relieving officers; that the certificate of any registered medical practitioner should be accepted as evidence of the nature of the infective character of the illness, and of the patient's fitness for removal, and that all charges incurred in the maintenance of the hospitals should be defrayed out of the metropolitan common poor fund, until such time as the hospitals themselves shall have been transferred to a

THE LANCET.

LONDON: SATURDAY, DECEMBER 11, 1886.

A GOOD deal has been said recently about the academic status of the Fellowship, chiefly in relation to the extra privileges over the Membership which it carries, and which its holders, by reason of their superior knowledge, are supposed to be better qualified to exercise and to enjoy. But by their latest action the Council have largely discounted this aspect of the diploma. As the result of outside pressure, and in the hope of depriving this pressure of much of its influence, the Council have been considering how to widen the basis on which the Fellowship is obtained, and the methods by which this object may be accomplished. They have decided that it is desirable to widen the basis, provided this be so done that the value of the distinction, as now held by the Fellows of the College, be not diminished. Yet in the face of this proviso the Council deliberately propose—(1) to elect annually a certain number of Members of the College, without any test as to their fitness for such an academic distinction other than a recommendation of five Fellows and five Members; and (2) to admit any Members of fifteen years' standing to the Pass without having passed the Primary Examination.

We have already discussed these proposals, and spoken not unfavourably concerning them; but we cannot admit that either the one or the other, and especially the former method, can be adopted without detracting in some measure from the present value of this now somewhat exclusive diploma. The adoption of the second proposal will not, in our opinion, be prejudicial to the purpose for which the Fellowship was originally issued—"in order more effectually to promote and encourage the study and practice of the art and science of surgery," as the Charter has it. But even this proposal must lower the present academic status of the diploma, seeing that the examination in anatomy and physiology—the *pons asinorum* of aspirants—is to be entirely abrogated. Nor is anything said about the preliminary art tests which the new order of Fellows shall have undergone. The purpose, however, of the Council being to increase the number of Fellows, it may reasonably be supposed that no stress will be laid on this point; this is the more certain as there has been a decided tendency on the part of the Council, during recent years, to lower rather than to raise this preliminary educational standard.

It would appear, then, that while resisting the desire of the Members of the College to more directly participate in its management, on the ground that acquiescence would be prejudicial to the vested interests of the Fellows and tend to lower the academic status of their diploma, the Council propose to elect annually a certain number of Fellows from among the Members, some without any of the tests on which the Fellowship at present rests and which give it the pre-eminence it enjoys, and some after a very modified test indeed. The professions of the Council and their practice are thus diametrically opposed. It must, therefore, [illegible] "have been elected to office as the governing body of the College," to come forward and say how long such an unwise and contradictory policy shall continue.

We have already, more than once, given our reasons for thinking that the extension of the franchise to Members of the College of, say, ten years' standing, and the concession of eligibility to sit on the Council to Members of twenty years' standing, need in no way either lessen the academic status or diminish the privileges of the Fellowship. The privilege of voting is not lessened in value because it is shared by others, while an increase in the present number of the Council by as many seats as it may be decided to offer the Members will deprive this concession to Members of any show of injustice to the Fellows.

Circulars will shortly be sent out to the Fellows to ascertain their views as to the desirability of extending the franchise to Members of a certain standing. The issue of large and important questions affecting the welfare of the College will be greatly facilitated should the Fellows of the College proclaim in favour of these concessions to the Members. An adverse vote, on the other hand, will at most stave off the final decision for a few months. We trust that the Fellows will see that their interests are really one with those of the Members in this respect. A retrospect of the action of the Council ought to convince even the most sceptical of the Fellows that they have little to hope for from the Council as at present constituted. A seat at the Council table is within reach of a very small minority of provincial Fellows, and can hardly, therefore, be reckoned as a tangible privilege of Fellowship. Voting for members of Council, which at present necessitates a journey to London, is at best an empty privilege, the entire abrogation of which would not make much difference to the majority of Fellows; how much less, then, will its being shared with the Members at large affect them, since they lose nothing by the concession.

Let the Fellows, on the other hand, make a stand on the question of facilitating the acquisition of their diploma on any other than on a strictly academic basis. In fact, ought not something to be done in the way of making this diploma still more select? Should it not be, in very truth, a test of *special* surgical attainments, and attainable by those only who are prepared to devote several years to its acquisition? An aspirant should not be allowed to pass the Primary Examination until he has been a Member of the College at least one year; and this examination should be of such a practical nature that only those can pass it who have been demonstrating anatomy and are intimately acquainted with dissected as opposed to text-book anatomy. The Final Examination should be equally searching, and require evidence of practical knowledge, of original work, of mature age, and of settled character before it can be obtained. Provision should also be made for withdrawing the diploma in case of misconduct or improper use. We feel sure that these are the points to insist upon, and that the time has come to abolish the merely political privileges of a diploma, which at present runs serious risk of being deprived of its academical status for the sake simply of perpetuating these privileges.

In connexion with the question of the relationship of the Fellows, Members, and Council of the College, we may

direct the attention of our readers to an article on another page, complementary of one which appeared in our issue of Oct. 30th of the present year. These two articles, taken together, are well calculated to rectify many erroneous views which appear to be still entertained on the history and constitution of the Royal College of Surgeons.

IT is disheartening to receive report after report revealing the unsatisfactory and even dangerous sanitary state of the towns and places to which the English people resort on their own coasts in order to find change of air and to recruit their health. It is not long since attention was drawn to the continued failure of the sanitary authority of Shoreham to deal with sanitary defects which had been pointed out to them, and which, in the end, were associated with a serious outbreak of fever emanating from one of the dairies of the town. The report of the medical officer of the Local Government Board soon followed with a description of similar places which should be avoided as health-resorts, and special attention was called in the volume to the circumstances affecting the rural area of the Isle of Wight. Indeed, Dr. BALLARD, in his general report on the sanitary survey which was made in anticipation of the advent of cholera into this country, puts forward the case of the rural sanitary district of that island as one typical of bad administration, and he instances conditions illustrative of the existence over a long series of years of some of the worst sanitary circumstances that could well obtain in such a district. A glance at our columns dealing with reports of medical officers of health will show how this official condemnation receives support from the local official. Dr. BALLARD'S report was soon followed by another relating to the maintained prevalence of diphtheria in East Cowes, this being issued in October last; and now we find that during holiday time at Swanage, in Dorsetshire, typhoid fever was widely prevalent there, and this under circumstances which should not exist in any town, far less in a place making profession of being fitted to serve as a health-resort.

The report in question[1] has been prepared by Mr. W. HARVEY, F.R.C.S., an officer of health of local distinction who was temporarily engaged in the service of the Medical Department of the Local Government Board, and from it we learn the following history. Swanage lies on the northern slope of the Purbeck Beds which in the valley opening out at Swanage Bay, consist of hard limestone exhibiting vertical faults or fissures every few feet. The rock is, in fact, one indicating easy permeability vertically and horizontally, the dip of the strata being from above down to the town, and a brook flowing through it. These conditions are so obviously of the first importance as regards many sanitary matters, that it might naturally be assumed they would have been held in view. But Swanage has 342 privies, with pits averaging about five feet in each of the three diameters, and these are "mostly situated in the Purbeck Beds." For other 150 houses, excreta and refuse are practically stored "on the ground" surface, the receptacles only being cleansed at long intervals, and even then the work is not undertaken by the authority. Some of the pits are in direct relation with the rocky substratum. Then, again, Swanage was without anything that can be called a system of sewers until some commencement in this direction was made last year, there being separate outfalls for liquid filth into cesspits, the brook, and the sea. Fortunately, as it might at first appear, the town has an inexhaustible supply of water from a deep well, and power was some time since taken by the authority, under an Act of Parliament, to purchase the water-works for the public benefit. But this has never been done, and the supply has only been laid on to 91 of the 562 houses in the town. Such a condition of things could, of course, only be justified by the existence of other easily available supplies of a really wholesome character. The report reveals the real state of affairs as to this. A pond and a spring are, in the first instance, reverted to without special comment as favourite supplies. Then comes a reference to two public and thirty private wells. These are sunk in the same permeable rock to which we have just alluded in connexion with privy-pits, cesspits, &c, and this rock is further spoken of as lying "below an ancient town, abounding with defective sewers, privies, cesspits, graveyards, and so on," the physical condition of the wells being such that "the pollution of all or many of them is inevitable." Here, then, we have precisely the conditions which are so well known, even by the least experienced of health authorities, to be identified with the spread of typhoid fever. But as regards the onset of epidemics of this disease, milk has of late years been a principal and prominent cause, and hence special attention has very generally come to be devoted to dairies. In Swanage, however, only one dairy has the public water-supply laid on to it; the others, with one exception, resort to wells, already described by Mr. HARVEY; and in the exceptional case the dairy premises are not only without any water-supply of any sort, but the dairy is "situated on the bank of the brook," which we have already learned is made to receive sewage.

Under these insanitary circumstances a case of typhoid fever makes its appearance in Swanage. It spreads to two other persons, and it is stated that there can be no question that the bowel discharges from the patients passed by means of a rubble drain into the brook. Then came a sudden outburst of disease, and up to the date of the report fifty-five persons had been attacked and three had already died. Now, reverting to the dairy without water-supply, it is stated that, like others, it has been under no sort of regulation or supervision. And not only so, but it actually had a "dipping-place" in the brook only a few yards below the outlet of the rubble drain with its now specifically poisoned contents. It would need no sanitary expert to prophesy what some day or another would be the result of such conditions. The milkman need not be asked whether he ever used the only available but polluted water-supply near to his premises. The milk soon told its own tale, for out of twenty-six cases during the first onset of the disease, twenty-two obtained their supply from the dairy in question. It was the smallest dairy in the place, and yet out of sixty customers about one in six families were [illegible] whereas only one in 150 not [illegible] Swanage it

[1] Sold by Knight and Co., Fleet-street; Shaw and Sons, Fetter-lane; Hadden, Best, and Co., West Harding-street; and P. S. King and Co., King-street, S.W.

could hardly be expected that, even when the source was suspected and dealt with, the disease could be stopped; and so it turned out. For, in the words of the report, typhoid fever having been started by the agency of milk, there were thenceforth other means ready at hand to continue the work—namely, "water-supplies, drains, soil and refuse heaps befouled by excrements," obtaining in manifold instances a specific character for their pollution. These led to a later renewed prevalence; and, as Mr. HARVEY says at the close of a very interesting report, "the experience is a familiar one." The public can easily judge who is most to blame—the small dairyman who only had two cows out of which he had to make a living, or the sanitary authority to whom the Legislature and the local community have delegated the care of the public health in this watering-place.

MR. BAILEY DENTON and Lieutenant-Colonel JONES, V.C., have submitted to the Metropolitan Board of Works a scheme for the disposal of London sewage, which deserves, but will probably not receive, careful and impartial attention. In its broad features it is no novelty, and is indeed practically the solution of the great difficulty which found most favour with the last, and perhaps the best, of the Royal Commissions on sewage disposal. It is, in fact, the Canvey Island scheme, which we have so often urged as the only one presenting a real remedy for the frightful evil which has so long disgraced the metropolis. Its feasibility is now admitted by all, for even Sir JOSEPH BAZALGETTE, who at one time believed it to be practically impossible, has submitted a plan for its accomplishment. In the hands of the skilful engineers who now bring it forward its success would not be doubtful. Properly executed, it would purify the river effectually, and would entail no injury on anyone.

The very existence of Canvey Island is probably unknown to the majority of Londoners, and even to many who have frequently travelled on the Lower Thames. In Sea Reach, on the left bank of the river, about ten miles below Gravesend and about nine above Southend, there is a small creek or haven called Holehaven, which is well known to barge captains and yacht sailors. Here begins the flat stretch of land known as Canvey Island. It is below high-water mark, and is enclosed by a massive river wall. Strictly speaking, it is only an island at high water, and it is far away from houses, and has very few of its own. To this island it is proposed to carry the sewage of the metropolis, including that of the Lower Thames and Lea valleys. The area is believed to be amply sufficient for the disposal of the whole for an indefinite period of time. Following the strongly expressed advice of the Royal Commissioners, the sewage is to be defecated, and we presume filtered through the soil, before it is allowed to pass into the river as a fairly clear effluent. We believe that no nuisance would be occasioned by the works; and to suppose that Southend would be injured by them or by the introduction of effluent sewage into the heart of the tide-way appears to us ridiculous. The suggestion comes with very bad grace from those who, for so many years and at so great an expense, have contended that the addition of the raw sewage at Barking and Crossness has not occasioned nuisance to Woolwich or Erith.

There is [illegible] to the practicability of this great and most desirable undertaking. The only serious question is as to its cost. Up to June next London has, it seems, the option of buying the whole of Canvey Island for a sum of £230,000. It is estimated that to carry down the sewage would cost £3,250,000, and the necessary works on the island £1,040,000. Taking the permanent expenses of pumping and treatment as £61,141, the annual cost to London would be £197,851, equal to a rate of rather less than 1½*d.* in the pound on the rateable value of the metropolis and lower Lea Valley. The cost of treating the sewage on the island is estimated at £20,000 a year only. Doubtless this means that the sludge is to be separated by simple subsidence without chemical treatment, the fluid portion being applied to crops and the sludge employed, without machine pressing, in raising the level of the land. We express no opinion on this suggestion, which appears to be the only debateable point in the scheme, but wait with the greatest interest for further particulars.

The important matter now is to force upon the attention of Government and the public this well-considered and promising scheme. We know well that the Metropolitan Board of Works, with remarkable obstinacy, has to the present time persisted in opposing the removal of the present outfalls. They are now preparing to spend an enormous sum in the treatment by chemical precipitation and deodorisation of the London sewage at Barking and Crossness. This expenditure will ultimately be wasted, for London will not long be satisfied with any system of costly tinkering. The chemical advisers of the Board, and particularly their chemist, Mr. W. J. DIBDEN, deserve all credit for the skill with which they have made the best of the conditions imposed upon them. But the conditions are wrong; and we can only hope that Mr. DIBDEN and his colleagues will shortly be able to apply their experience and skill in a district where real and final success may be obtained. If the members of the Metropolitan Board only realised how much of their increasing unpopularity is due to their contempt of the just complaints of Londoners about the condition of the Thames, they would perhaps change their tactics before it was too late, and would push forward the reform which they have so long opposed.

THE science of physiology has been Dr. GASKELL'S field of investigation for many years back. His conclusions, too, have received a very large measure of acceptance. The work which he has recently accomplished on the relations of the sympathetic nervous system to the central nervous system is also characterised by scientific methods, and the conclusions bear the impress of truth. We must remember, however, that the advancing zone of physiological knowledge, whilst it is supported by a nucleus of ascertained truth, is nevertheless subject to fluctuations which are not always actual contradictions. The object Dr. GASKELL had in view in his lecture at the Royal Institution of Great Britain was to give the deathblow to BICHAT'S teaching that the cerebro-spinal and the sympathetic systems were co-ordinate. Dr. GASKELL appeared to prove conclusively that the whole sympathetic system was nothing more than an outflow of visceral nerves from certain nerve centres in the cerebro-spinal system. It was shown that the sympathetic nerves do not send non-medullated fibres into the cerebro-

spinal system, because all these fibres pass out of the nerve-roots before they reach the spinal cord. White or medullated nerve fibres constitute the only link between the sympathetic and cerebro-spinal systems, and this link is always by way of the white rami communicantes. Consequently the connexion between these two nervous systems is limited to the region of the white rami communicantes; that is, to the region between the second thoracic and the second lumbar nerves. Further, these conclusions are borne out when an attempt is made to follow the white rami communicantes into the central spinal axis by means of their structural peculiarities. Sections of osmic acid preparations show that each white ramus is composed of very small medullated nerve fibres, often seven times smaller than the large medullated nerve fibres which compose the bulk of the anterior nerve roots. It would therefore be easy to demonstrate the fibres of the white rami communicantes in the anterior nerve roots wherever they are present. Observations proved that in the dog these small white rami were present only in the thoracic part of the spinal cord. Further observations showed that the communication of the sympathetic and cerebro-spinal systems is not symmetrical throughout, but consists of three distinct outflows of characteristic visceral nerves—(1) cervico-cranial, (2) thoracic, and (3) sacral; the break in the continuity corresponding to the exit from the cord of the nerve bundles that supply the upper and lower extremities. Dr. GASKELL then went on to show that the accelerator nerves of the heart left the spinal cord in the anterior nerve-roots as fine medullated nerve fibres, and that after they had passed through the ganglia stellata they had become non-medullated nerve fibres. And this transition obtains throughout, for not only do the accelerator, but all the vaso-motor nerves change their coats in the same way in passing through the sympathetic ganglia. Besides losing their medulla, they have increased in number by a process of division, so that the efferent fibres of the ganglia are more numerous than the afferent. Seeing, then, that the sympathetic (non-medullated) nerve fibres are throughout modified medullated nerve fibres (cerebro-spinal), and do not arise independently in the sympathetic ganglia, we may fairly regard the sympathetic ganglia as bearing the same kind of relation to the visceral nerves that the ganglia on the posterior nerve roots do to the ordinary sensory nerves. ONODI has shown that the sympathetic are developed in close connexion with the posterior root ganglia, and travel further away from the central axis as the animal grows. Finally, argues Dr. GASKELL, the meaning of the sympathetic as a simple outflow of the ganglionated visceral nerves from certain portions of the cord and bulb is to his mind conclusively settled by the intimate relationship that exists between the structure of the spinal cord and the presence or absence of the rami viscerales. CLARKE'S column of cells is limited to certain parts of the cord and bulb. It is conspicuous in that part of the cord that lies between the second thoracic nerve and the second lumbar nerve. It is seen, again, in the top of the cervical cord, and extending into the cranial region. And, lastly, it occurs as an isolated patch in the sacral region of the cord. In other words, its cells correspond in distribution to those parts of the cord that give origin to the white rami communicantes. Hence the conclusion is drawn that the white rami communicantes arise in the cells that compose CLARKE'S column. On this showing the whole of the visceral nerves of the body are of spino-bulbar source.

A BILL which is backed by more than one distinguished member of the medical profession deserves for this reason careful consideration. Its object—that of promoting the sanitary improvement of dwelling-houses—is one that will command the respect of all who desire to see the removal of causes of disease and mortality. We felt, therefore, no hesitation in recently expressing sympathy with these intentions of the Bill which has been prepared by Mr. MARK JUDGE, but at the same time we doubted whether his proposal could be seriously entertained. Mr. JUDGE has now placed his views upon this subject before the Association of Medical Officers of Health, in a paper which he read to the Society; and the discussion which it elicited is fully in accord with the opinions we ourselves entertained concerning this measure. Mr. JUDGE was able without difficulty to show that dwelling-houses are now constructed in such a manner as to endanger the health of their inhabitants, and he does not limit his condemnation to those which have been erected within the last few years; it may, indeed, be admitted that a very large proportion of habitations in existence at the present time fail to fulfil satisfactorily the requirements which we have learnt to regard as necessary for the full enjoyment of health. He is desirous, therefore, that every house should be examined, that if found wanting in the sense we have indicated the defect should be remedied, and that by this process it should be ensured that every dwelling in the kingdom is fit in the best sense of the word for human habitation.

There is no section of our profession which would more willingly accord support to this principle than that which is engaged in the important duty of preventing disease. Nevertheless, there is no question that the Society of Medical Officers of Health have practically condemned as unworkable the means by which Mr. JUDGE proposes to accomplish the much-desired end. His suggestion that the vast process of reconstruction should be completed in the course of a few months shows either a want of appreciation of the character of the work that has to be performed or of the condition of a large number of houses in the metropolis and elsewhere; his intention to entrust the work to members of various professions who have but an elementary knowledge of the conditions which have to be fulfilled is another reason for doubting the practicability of his scheme. It was not difficult for Professor CORFIELD to plead, on behalf of those whose practice embraces specially the removal of unhealthy conditions, that the chief effect of such proposed legislation would be to employ a large number of persons altogether incompetent to properly perform this duty; and, again, it was easy for others to argue that the possession by a house-owner of a certificate under these circumstances would strongly militate against the improvements which are slowly being carried out in many of the larger centres of population.

The Bill as it stands must therefore be condemned; but although the machinery which it was proposed to bring into action for the improvement of dwelling-houses has been [illegible], the fact remains that

there is a great necessity for some further powers for the attainment of the object it had in view. It is in no way obvious to us that the Legislature has failed to recognise the importance of this subject and to provide the means which are necessary for the purpose. The want that really exists is that which concerns the constitution of local authorities; and it is this difficulty which is now engaging the attention of statesmen. Nowhere is this obstacle to the enforcement of sanitary law more keenly felt than in the metropolis, and nowhere is there more opposition to any rearrangement of constituted authorities. The only influence which can overcome this opposition is that of public opinion, and this, so far as the metropolis is concerned, it is almost impossible to create. The demand for municipal reform is, indeed, left to those who have personal knowledge of the disadvantages attendant upon the present system, and, perhaps, to those who for other reasons desire to ally themselves with this movement. The Home Secretary's reply to a recent deputation on this subject, that their views deserved attention, inasmuch as they represented authorities which had failed in their duty, was doubtless not made without reason. To those who are watching the course of events with regard to municipal reform, and who are desirous of seeing an authority called into existence which is worthy of confidence, there was something almost farcical in the constitution of the deputation which waited on the Home Secretary and the President of the Local Government Board. It is probable that all who shared in the appeal to those gentlemen were not cognisant of the position in which they were placed, but there is the greater necessity for those who wish London well to bestir themselves in this matter, and not to leave to mere chance the future constitution of the authority, which will eventually have to deal with even larger problems than that Mr. JUDGE submitted for the opinion of the Society of Medical Officers of Health.

THE conference held at the Society of Arts, John-street, Adelphi, on Tuesday last, under the presidency of Sir ANDREW CLARK, was rather a lively one. The presence of the Chairman, of Sir SPENCER WELLS, of Mr. TIMOTHY HOLMES, and other consultants, shows how deep is the interest in the problems discussed, even among those who have no personal interest in the subject. The question, as it affects London, is altogether a special one. More limited communities are infinitely more favourable for experiments in the way of provident dispensaries. Even in these such experimens are not easy, and have not been altogether satisfactory. But in a community, or a congeries of communities, like London, the organisation of provident dispensaries on a sound basis is a matter of extreme difficulty. The Metropolitan Provident Medical Association has now been in existence for several years, backed by many prominent members of society, who formed themselves into a Joint Stock Company. But it does not appear to have had any great success. It has never been popular in the profession, and it seems to have been scarcely more so among the people for whom it was intended. The secretary stated, in answer to a question, that there were about 25[illegible] medical officers, and that the amount paid [illegible] to 100*l.* per annum. This [illegible] Leicester Provident Dispensary, which includes a quarter of the inhabitants. The explanation usually given of the non-success of the Metropolitan Provident Medical Association is the competition of the great hospitals and the free dispensaries of London, and especially the abuse of the out-patient department. This was the explanation on which Mr. TIMOTHY HOLMES laid most stress on Tuesday, and the speeches of many of the medical men present showed that it was their view of the matter. But there are other reasons for the comparative failure of the Metropolitan Provident Dispensaries; at any rate, there are other reasons why they have been unpopular in the profession. The first is that they introduced a low rate of charge, and this at a time when in most parts of the country an effort was being made, with more or less success, to raise the rate of pay in club practice. Secondly, they threw their net for all comers, without reference to their wages or their means. Thirdly, they entered into negotiations with the friendly societies and other such bodies, which were already provided with medical officers. It may readily be understood that such tactics were most objectionable to medical men. They did not raise the estimate of medical service. They took or tempted the patients of other medical men, and, instead of working in new seams and among the improvident, they catered for those who had already entered into provident arrangements of their own. We pointed out these errors from the beginning, and have noticed with regret that our remonstrances were unheeded. The meeting of Tuesday was largely occupied with a statement of those grievances by various speakers, in more or less methodical form. But undoubtedly the out-patient department of hospitals was much spoken against. It was said to be grossly abused. Mr. GEORGE BROWN proposed an amendment strongly denouncing it. Sir ANDREW CLARK was disquieted by the free way in which charges were brought against it, and proposals made for its abolition. As we have said, he had to use his best influence to prevent a very strong resolution against the out-patient system, which, in his opinion, would have greatly reduced the value of hospitals as places for learning the art of medicine; and he had also to protest against a statement that out-patients are often treated by students. It is enormously important in all such discussions to observe care and accuracy of language. No member of the profession would like to say a word that could really injure the hospitals in which he has largely learned his profession, and in which the poor find a refuge in their dark days of sickness and accident. At the same time, it is evident that hospitals must restrict themselves more and more to their proper sphere, and not compete with practitioners. The treasurer of Guy's seemed surprised at the meeting not being delighted with the system now practised at that hospital of charging the poor a few pence for their medicine. This is a mockery of a provident system, and an equal mockery of charity. We do not believe that there exists any abuse of hospitals to justify the withholding of a sixpence from them. It is important at this benevolent season to be explicit on this point. But they might do enormous good to the poor to the public, and to themselves, by working with and into the hands of provident dispensaries. The committee which has been appointed may earn for itself great gratitude [illegible] a study of these questions and such suggestions as will

lead to mutual respect and coöperation between the staffs of hospitals and those of provident dispensaries. The affirmation that attendance on the sick poor should be on the principle of sick assurance, the directing of the attention of the governing bodies of hospitals to the necessity for some check on the indiscriminate provision of medical treatment and dispensaries, and the appointment of a committee to report on the subject of assurance as applied to the sick, was not bad work for a somewhat divided and excited meeting. The interests of the profession and those of the poor alike call for wise and prompt action by this committee.

Annotations.

"Ne quid nimis."

DEGREES FOR LONDON MEDICAL STUDENTS.

THE position in which the question of degrees for London medical students is now placed must quickly bring some one of the various solutions of the difficulty to the forefront. The grievance to the London student, and to the various provincial schools, which have not as yet been able to combine into a university, or do not constitute an integral portion of a university, is admitted on all sides. Sir James Paget, as Vice-Chancellor of the University of London, publicly said in Manchester last month that "although some schemes were afloat which rather implied that the University of London should be the great body in England for granting the degree of Doctor of Medicine, that was not likely to take place," so that it is obvious that, except for some minor internal reforms, the authorities of the University will defend the *status quo*, and that average London students must look elsewhere for a medical degree on terms equivalent to those granted by the other Universities in the United Kingdom. The only suggestions entitled to consideration for removing this disadvantage to the London student are—(1) the establishment of a Teaching University in London; and (2) the constitution of a University, primarily medical, of which the medical schools should form the Medical Faculty, under the auspices of the Royal Colleges of Physicians and Surgeons in London, and around which the other Faculties should gradually congregate, and become component parts. If the students are to be allowed to obtain degrees on as fair terms as those which exist in other medical centres, one or other alternative must take the lead in affording the solution to the difficulty. The Association for promoting a Teaching University in London, which will hold a general meeting on the 15th inst., will present a report and urge the advisability of approaching Her Majesty's Government on the question. It is further understood that the Committee of Delegates of the two Colleges will lay before special meetings of the Council of the Royal College of Surgeons and of the Comitia of the Royal College of Physicians respectively, on the 16th inst., a report passed by the Committee, to the effect that candidates who have qualified at the Conjoint Examining Board, after having passed an examination in arts and science to be subsequently defined, should obtain a degree in Medicine and Surgery, but which will also assert that the Colleges and the associated schools form practically a Medical University. There are two questions in this proposition of great interest—viz., what constitutes a Medical University; and is residence to be an absolute necessity for a new Medical degree? We venture to look for some approximation between the academical and the purely professional aspects under which the question is at present being debated, and we hope that on such lines some speedy solution will be found which will remedy the admitted hardship which the London medical student experiences when he honestly and fairly asks for a degree on similar terms to those which obtain with his Scotch and provincial brethren.

GALEN AND HIS WORK.

MODERN science has been accused of an ignorant and irrational contempt for its early precursors. No doubt the excessive admiration in which these masters were held incurred the inevitable reaction; but now that both extremes have had their day, a far more enlightened and far higher estimate of their lives and work is steadily being formed. Galen is an example in point. After sharing with Aristotle something like despotic sway over the schools, and suffering with him the neglect and even odium meted out to dethroned monarchs, he is now restored to his proper place in the order of history and rehabilitated with the honours he is justly entitled to. In the words of a living master of inductive research, "it is impossible too greatly to admire the really astonishing fidelity with which this early biologist adhered to the true methods of science. Many a worker of the present day would do well to take a lesson from the patient and laborious diligence with which Galen applied himself to the accurate study of facts, and no less profitably might many of them imitate Galen in the caution which he displayed in the province of speculation. Regarded as a scientific genius, Galen is second to no man in history. It is certain that he was charged with the true conception of scientific methods more fully than any of his predecessors, or than any of his successors, till within the last few centuries." It is one of the many causes of regret for the arrested labours of the Old Sydenham Society that the same office, so well discharged by the late Dr. Francis Adams for Hippocrates and Aretæus among the Greek physicians, was not extended to Galen, and that a faithful English version of at least his medical writings was not placed within reach of the higher order of students. German criticism has recently done signal service in reconstituting the text of these writings; and when this necessary work has been completed, let us hope that English scholarship will have preserved enough of the sound traditions of Adams and Greenhill to provide a new interpretation of the text so purified and established. Archæology has also made her contribution to the better understanding of the great physician of the Antonines, and has almost placed her finger on that spot in the Forum Romanum where the philosophic practitioner was burnt out of house and home in the disastrous conflagration under Commodus. Art, too, is thus enabled to give pictorial rendering to one of the most dramatic situations of science, and Alma Tadema might well be trusted to do for medical what he has so happily achieved for industrial and social antiquity.

THE METROPOLITAN ASYLUMS BOARD.

THIS Board met again on Saturday, and once more determined to adhere to their previous resolution to erect a permanent small-pox hospital at Darenth. They expressed their willingness to elaborate and submit a scheme and plan for the approval of the Local Government Board at the lowest cost consistent with efficiency for the purposes intended; but this hospital is to be built of brick, and therefore a permanent structure. This serious division of opinion threatens to be fraught with danger to the metropolis. It is more than probable that further accommodation for small-pox will be required; it is equally certain that the proper time for its preparation is when the disease is absent from London, and it would be a grave misfortune if the demand for hospital provision should come before the [illegible] requirements of an epidemic.

The correspondence which has appeared in the daily press on this subject seems to have shown that the difficulty of the Local Government Board is not as to the spending of a few thousand pounds more or less, but in determining the best method in which they shall be laid out. Whether the hospital to be erected be a temporary or permanent structure, we fear there is little doubt that the money will serve but for the purposes of the moment. London would probably not object to this inevitable sacrifice if it were clear that these Boards were determined without loss of time to institute a continuous and searching examination into all the circumstances of hospital influence. The opportunities for this investigation have in the past been very partially utilised. The past cannot be undone, but there is the strongest necessity that the continuance of this want of systematic observation should cease. At the present moment the question before the public is that of the expenditure of money. It must not be forgotten that bound up with this question is the more serious expenditure of human life. To wait for changes in London government which would call the necessary organisation into existence is to trust to an unknown future, and to hopes that may not be realised in this generation.

ALCOHOLIC OR PNEUMONIC DELIRIUM.

ON Nov. 29th Dr. Danford Thomas held an inquest at the Paddington Workhouse touching the death of John Barnes, aged fifty-one. Deceased had given way to drink of late; and a week prior to his death he was seized with acute illness, ushered in by tremors, pain in the side, and cough. Getting rapidly worse, he was seen by Dr. Hibberd, the out-door Poor-law medical officer, who ordered his removal to the Paddington *Infirmary*—the infirmary is a distinct institution from the workhouse, and is under a separate board of management. The certificate given by Dr. Hibberd was to the effect that the man was suffering from a severe cold, and was very ill. Unfortunately, it does not appear that mention was made of the existence of pneumonia. Deceased was taken in a cab to the infirmary, where he was seen by the medical superintendent. This gentleman, finding the patient delirious and labouring under delusions, came to the conclusion that the case was rather one for the padded room of the workhouse than for a ward in the infirmary, and consequently he endorsed Dr. Hibberd's certificate: "This appears to be a case for the strong room." Although the infirmary and workhouse are adjacent, we hear that an hour and a half elapsed before deceased was put to bed in the latter institution. At this season of the year such delay might well turn the balance between the chances of a fatal and favourable issue; but in the case under consideration it was stated in evidence that deceased had succumbed to double pleuro-pneumonia, from which he could not recover. A day or two before his death deceased became delirious, wandered into the street in his shirt, and had marked illusions of the senses, mistaking a pair of braces on a chair for somebody's legs. Moreover, he was subject to hallucinations; and, in short, if he did not actually have delirium tremens, he had something very like it. An important point raised at the inquest was with regard to the nature of this mental aberration. Was it alcoholic, or was it due to pneumonia, or both? Mr. Pepper stated that, in his opinion, a person who had previously been recently drinking hard, whether he had had delirium tremens or not, would be very likely to develop delirium tremens on the incidence of acute pneumonia, the sudden onset of a severe inflammatory disease acting as a shock to the nervous system much in the same way as would a physical injury. We are not informed if the patient's chest was examined; we imagine not, for had the medical superintendent been aware of the condition of the lungs he would assuredly have taken measures for the instant admission of the man, and we fully endorse the views of the coroner that resident medical officers of public institutions would do well in any case of doubt to admit the patient. A few hours would soon clear up the problem, as they did by death in Barnes's case. It is unfortunate that the Paddington Workhouse and Infirmary should be almost within touch one of the other, and that they should have separate medical departmental officers. Is there a special room in the infirmary for casualty cases?

HOSPITAL APPOINTMENTS AND DEGREES IN SURGERY.

THE holders of University degrees in Surgery complain that they have a great grievance in the fact that these degrees do not qualify them for surgical appointments in many hospitals. This is a matter of some significance and of much consequence. English hospitals are not State institutions, and it is competent to their voluntary subscribers to require any particular qualification they please. But it is certainly anomalous that the holders of University degrees in surgery, though qualified to practise on all Her Majesty's subjects, are not qualified to hold surgical office in many hospitals. Similarly the membership of the English College of Surgeons does not qualify for many hospital appointments, and some of our most distinguished surgeons have had to go to the Edinburgh College and ask for a Fellowship on terms very different from those upon which the similar qualification is granted in England. The matter is not one for the General Medical Council so much as for those bodies whose licentiates and graduates are injured by, not the law of the kingdom, but the bye-laws of hospitals. We should advise our correspondents, in the first instance, to address themselves to these bodies, and ask them to make representations to the hospitals which make distinctions unknown to public law.

"LEARNING HOW TO LEARN."

IN the course of his very apposite and suggestive remarks on the occasion of distributing prizes and certificates to the successful candidates at the London centre of the Oxford Local Examination on the 1st inst., Sir James Paget laid especial stress on the importance of "learning how to learn," and did full justice to the proposition that knowledge not immediately useful in itself may be the means of developing *this power of learning* in the mind acquiring it. This is a great practical truth, full of force and value. We are not at the moment concerned to determine whether classical or scientific knowledge is of the greater worth, looked at from the strictly utilitarian standpoint. There may be wide differences of opinion on that topic, and it is no secret to our readers that we entertain a strong opinion that the growing neglect of classical studies is an evil to be deplored. The question of the instant, however, is the need of "learning how to learn." To every student, and especially the student of the science of health and healing, who has to obtain something more than "a smattering" of many branches of knowledge, it is of the very highest practical importance to recognise this fact. The cultivation of the faculty of knowing is of incomparably greater moment than the mere acquisition of knowledge. He is not the best of explorers or campaigners who is the most burdened with baggage, but he who knows how to forage well and how to make the best possible use of what he has or can obtain. So it is with the student: to know how to learn, so that when need arises knowledge may be quickly obtained, is a better provision for the business of life than is afforded by the largest or richest store of information packed away in the memory—perhaps

so packed as to be inaccessible when wanted. If students for themselves, and teachers for their pupils, would insist on the importance of "learning how to learn," instead of cramming, there would be fewer disappointments in life and greater and more enduring successes. The vanity of carrying a huge quantity of information for the sake of display is contemptible. The folly of attaching any real value to vast stores of knowledge is pitiful. The only brain property worth carrying about is the power of finding at pleasure and learning at will precisely what is wanted; and this power cannot be acquired without considerable practice in the art of learning—an art which the student should make it a first object of his best endeavour to master.

STEEPLECHASE ACCIDENTS.

IN a contemporary of the 3rd inst., it was reported that at the recent Croydon meeting a jockey had to wait a considerable time before a substitute for a bandage could be obtained wherewith to bind up his injured body. Considering the popularity of steeplechasing and hurdle-racing, the number of meetings, and the peculiar dangers risked by riders, we agree with the suggestion made that the Grand National Hunt Committee should take steps to see that ordinary surgical appliances are always ready to hand. Excluding fatal and exceptionally severe injuries such as fracture of the skull, the most likely mishaps are cuts and bruises and simple fractures, especially of the clavicle. The degree of suffering in such cases is minimised by prompt and careful attention, even that which an ordinary "unskilled" person can render. But we would go a step further and urge that a pastime which counts thousands for its votaries, and implies the outlay of large sums, is surely able to sustain the expense of paying for the attendance of a qualified medical man at all meetings held under the Hunt rules. We doubt not that if the services of a doctor could be requisitioned immediately, many cases of accident which might otherwise prove serious would be kept within the limits of a favourable prognosis. Compare, for example, the danger in cases of simple and compound fractures, in which too often one of the first rules of surgery is contravened for want of adequate and reasonable surgical aid; we refer to the converting of a simple into a compound fracture.

PUBLIC HEALTH IN CALIFORNIA.

THE ninth biennial report of the State Board of Health of California is a document full of promise for the future sanitary history of that State. It indicates throughout that an increasing amount of attention is being bestowed upon considerations affecting the sanitary welfare of the people, and it points out the lines for future action and for such legislation as is needed, in order to secure the end in view. From the Secretary's report it would appear that diphtheria has been epidemic in San Francisco, that it has prevailed as an endemic in various parts of the State, and that its precise origin is no more understood there than it is in this country. Enteric fever is also a source of considerable alarm, and, with a view of preparing the State to cope with it, an excellent summary of the various scientific opinions as to its origin and means of diffusion in Europe and in America is set out. The need for quarantine restrictions, in order to keep out such diseases as cholera, yellow-fever, and small-pox, especially in connexion with the sea traffic from Japan and China, is strongly enforced; and in the absence of compulsory vaccination in the case of small-pox, and in view of the peculiar climatic conditions of the State as to the other diseases, greater precautions may be necessary than can effect real good in Europe. But what is wanted in America is the establishment of some general principles of action rather than the intermittent and varying action of a number of separate States; and we entirely sympathise with the request which has gone forth from more than one State, that the general health defences of the country should be subject to some central organisation, whether this be by the rehabilitation of the National Board or by the construction of some new body. The appendix to the report contains a number of interesting papers on the physical, social, climatic and other aspects of California, and other matters having a sanitary bearing on the State.

SANITARY PROGRESS AT THORNHILL.

As a part of the cholera survey which has for some time past been in progress under the surveillance of the medical officer of the Local Government Board, Dr. Barry recently visited Thornhill, a local board district in the vicinity of Dewsbury. He informed the authority that he had made his inspection on the lines adopted in the same district in 1878 by Dr. Thorne Thorne, and he was able to compliment the authority on many satisfactory evidences of progress since that date. The public water-service was now carried throughout the district, scavenging was fairly well in operation, and with regard to the abolition of the great midden-privies, to which Yorkshire and Lancashire still cling so tenaciously, Dr. Barry was able to say that greater progress had been made in Thornhill than in any other portion of the Dewsbury district. In three vital respects, in so far as danger from cholera is concerned, Thornhill has done well; but all risks attaching to filth will not be removed until the question of an efficient system of sewerage is dealt with. This is an admitted difficulty, but it will be well that it should be faced without delay. Old and antiquated bye-laws are also a hindrance to proper and wholesome house construction, and this the authority should find no difficulty in altering. Thornhill has always been a progressive district, and we trust it will not be content until all its sanitary arrangements have been placed on a satisfactory footing.

RAILWAY COUPLINGS.

ON the 2nd inst. a number of tests were made at Derby with the prize waggon couplings shown at Nine Elms in March of this year through the offer of a prize, the object of which is to prevent the present loss of life among waggon couplers. The contrivance which at the last demonstration elicited the most unanimous approval is a light pole, about 5 ft. 6 in. in length, with a skilfully devised hook at the end, by which the chains can be attached or set free in wonderfully short time. One man ran along twenty waggons and uncoupled them in seventy seconds; another coupled them again in seventy-six seconds. This plan has been in use on the Midland Company's system for some time, and has led to a decided diminution of accidents. It is to be hoped that other railway companies will speedily take steps to terminate or materially diminish the slaughter which annually results from the goods guards and shunters having to pass between the waggons to couple and uncouple them.

DAIRIES, COWSHEDS, AND MILK-SHOPS.

THE subject of the powers and duties of sanitary authorities and their officers under the Dairies, Cowsheds, and Milkshops Order of the Contagious Diseases (Animals) Act of the present year will be discussed by the Society of Medical Officers of Health on Friday next, at 8 P.M., when Mr. Alfred Ashby, M.B., F.R.C.S., Medical Officer of Health of Grantham, will read a paper thereon. It is convenient that so early an opportunity has been afforded for enabling health officers to confer together upon this matter.

THE METROPOLITAN BRANCH AND THE SOCIETY OF APOTHECARIES.

AT the meeting held on Friday Dec. 3rd, at the School of Mines, both of the principal resolutions brought forward were adopted. That relating to the question between the Colleges and the Apothecaries' Society was in accordance with the views we have expressed on the subject. The probable effect of the extinction of that Society as a legal and frequently effective check on spurious practice was insisted on. This has much practical significance, but it by no means constitutes the chief difficulty with which the profession has now to deal. Of far greater importance would be the creation of the Society's diploma into a rival qualification in medicine. It is hardly necessary now to recapitulate the reasons given in a former article which led us to deprecate such a step. Another question discussed at Friday's meeting was the representation of Members of the College of Surgeons and Licentiates of the College of Physicians on the Councils of their respective corporations. The resolution relating to this was also carried.

MORBID SENSE OF RESPONSIBILITY.

PEOPLE sometimes think that medical men are apt to look upon their patients as machines or as corpora vilia for their experiments. How very far this is the reverse of the truth is probably only known to medical men themselves. Indeed, the sense of responsibility is sometimes exaggerated to an abnormal or morbid extent, as is shown by a very sad occurrence which, as we mentioned last week, has just taken place at St. Petersburg, resulting in the self-destruction of one of the most gifted and esteemed surgeons there, Dr. S. P. Kolomnin, Professor of Clinical Surgery in the Military Medical Academy. He had to perform an operation on the rectum of a woman, and for the purpose employed cocaine anæsthesia; the patient died in a very few hours after the operation from cocaine poisoning; at least, that is what is considered to have been the cause of death, but no details have as yet been published. The sad result took such a hold on the mind of the unfortunate operator, that, though his colleagues did their best to reassure him, and to show him that the result should be ascribed to an accident such as most surgeons have occasionally met with, it was impossible to prevent him from considering himself the culpable agent in the woman's death. This so preyed upon his mind that he shot himself with a revolver on November 23rd.

THE LLANDUDNO COTTAGE HOSPITAL.

THIS Cottage Hospital, which can now make up beds to the number of thirty-five, has issued its fifth annual report, statement of accounts, list of donations, &c. The building is now completed, and the trustees make an earnest appeal for increased subscriptions, in order to pay off the outstanding debt. The number of patients admitted has increased gradually during the last three years, and in the last year eighty patients were treated in the institution. There are five gentlemen whose names appear as honorary medical officers, which are more than sufficient to do the work of the institution, and as the list does not include the names of all those practising in the town, we do not see why the names of these are not included. As this is a cottage hospital, all the medical practitioners of the district ought to have the privilege of attending their patients, and of obtaining equal advantages from it. The number of practitioners not included in the staff is not large, but it would add to the efficiency and advancement of the hospital if they were granted what is only just to them—whereas, No. 4 of the rules, which [illegible] decidedly tends to produce unpleasantness. Surely the other medical men in the town are quite as capable of certifying the non-infectiousness of cases which they recommend for admission as are those of the honorary staff. A more careful revision of the names of the diseases from which the patients were suffering would improve that portion of the report.

CHARCOT'S JOINT DISEASE.

AT the meeting of the Berlin Medical Society on the 17th ult. a discussion took place upon Tabetic Arthropathy, which, it may be remembered, excited so much attention at our Clinical Society two years ago. Dr. Rotter, who opened the debate, described succinctly the clinical and anatomical features of the disease, with a view of proving its distinct identity, and the dependence of the articular changes upon nerve disorder. Professor Virchow followed in a long and careful speech, in which he acknowledged the similarity of the affection to rheumatoid arthritis, and traced the development of the pathological changes in the joints from hyperplasia of the cartilaginous investment, followed by regressive change and atrophy, ossification of the medulla leading to eburnation, hyperplasia, and ossification of synovial fringes, and ultimately of ligamentous tissues. These changes, he declared, were hardly to be regarded as inflammatory; but, although he admitted their dependence upon disordered nerve influence, he maintained that in each case there must be a local determining cause also at work. Other members also spoke, but we must postpone a full analysis of the debate to a subsequent occasion. Neurologists will note that Professor Virchow objects to the phrase "tabetic," and prefers that of "arthropathia tabidorum."

"SHELTERS" FOR 'BUSMEN.

THE 'busmen need "shelters" fully as much as, even if not more than, cabmen. The work of the former is more continuous and exacting than that of the latter. The drivers are seated, reins and whip in hand, and the conductors are standing throughout long journeys, whether the vehicles be full or empty. These journeys succeed each other with such rapidity that practically the men have little or no time for their meals, and most of the refreshment they can procure during the twelve or sixteen hours they are on duty consists of "two's" or "three's" of gin, hot or cold as the case may be, with scarcely any food, and what little there may be nearly always cold. It is therefore quite necessary, in the interests of health and morals, that this class of public servants should be provided with places wherein to rest, to cook their food, and be allowed time to eat it. We trust this reasonable demand will not be either rejected or neglected.

BORATED FISH.

THE question to decide in connexion with the employment of boracic acid as a preservative of fish is not the economic or the commercial one. The point is whether the use of boracic acid is calculated to deteriorate the fish as an article of food, or to cause derangement, not to say disease, in the human economy. Nothing short of the experimental method will afford a decisive and accurate conclusion. But we tread on safe ground when we assert that fish perfectly fresh, and kept no longer after its removal from the watery element than is absolutely unavoidable, must be considered to be a better article for consumption and less liable to effect harmful changes in the organism than any kind of borated substitute. However, if fish must be preserved, are there any known facts that should recommend the employment of boracic acid? It is a good antiseptic, and will undoubtedly prevent putrefaction if used in sufficient quantity. Does it cause disease when

introduced into the healthy human body in minute doses and for long periods?. It certainly is of value internally administered in some morbid conditions of the stomach and intestines. For the last question we have no certain data on which to give a satisfactory answer. But we should think that, if used occasionally and in very small quantities, the acid would probably not prove injurious to the health of the animal organism. It may be urged that washing, boiling, or cooking would free the fish from any boracic acid that might have penetrated into its substance, but probably some of the salt would remain in the fish. The salicylage of beer is a more wholesale saturation, both of beer and consumer of beer, but, so far as can be judged *a priori*, the use of boracic acid to preserve fish, though not desirable, would with proper precautions not prove harmful.

THE PURITY OF MID-ATLANTIC AIR.

In the course of an address on the Action of Micro-Organisms on Surgical Wounds, Professor F. S. Dennis of New York states that during his last trip across the Atlantic he made some experiments to test the purity of the air about 1000 miles from land. He employed capsules of sterilised gelatine, and exposed them for fifteen minutes. One capsule was exposed in the state room upon the main deck of the steamer. Within eighteen hours over 500 points of infection had developed. Two capsules exposed in a similar manner in a cabin on the promenade deck, where the circulation of air was free, showed five or six points of infection each ten days afterwards. A capsule exposed over the bow of the ship was found to be entirely uncontaminated. These experiments are on the same lines as those of Pasteur and Tyndall upon the mountain air of Switzerland, and, so far as they go, they show the germless condition of mid-oceanic air, and also the need for much more efficient ventilation in the state rooms of even the first-class American liners.

SCHOOL HYGIENE IN SILESIA.

A petition has been sent to the municipal authorities in Breslau emanating from the hygienic section of the local scientific and educational association, and signed by twenty-six medical men, pointing out the great importance of medical supervision for schools, and suggesting that on school managing committees one in every four members should be a doctor. The signatories also offer to undertake the duties of school medical officers gratis, so that there may be no objection raised on the ground of expense. It is mentioned that for some months past the Grand Duchy of Baden has appointed medical men on all the school management committees. The petition concludes by asking that one doctor shall at once be appointed on every school management committee, he on his part promising to give his services as medical officer to the school.

THE ROYAL UNIVERSITY.

Our Belfast correspondent writes:—"The Senate of the Royal University have again been making most extensive alterations in the medical curriculum, to which direction has been drawn by your Dublin correspondent. These frequent changes do not tend to give students much confidence in the stability of the University. It was thought that the chief function of this University was to be that of an Examining Board, but the Senate now go much further and specify the exact course that the medical students are to take each year. The popularity of the University is not increasing, and in Ulster the feeling is growing that in the present unsettled condition of political affairs in Ireland the life of the Royal University will not be a long one."

NEW SPANISH MARITIME SANITARY SERVICE.

The Spanish Government has at last awakened to some sense of the importance of guarding against the importation of epidemic diseases by sea, which was the route by which the last serious visitation entered, the attention of the officials being almost entirely concentrated on guarding the land frontiers. The *Gaceta*, however, published on Nov. 17th, contained a series of regulations creating a "maritime sanitary service." Four classes of ports and *lazaretos* are named. The first comprises thirteen of the most important, such as Barcelona and Cadiz; the second includes Huelva and Seville; and the third and fourth, smaller or less important ports. The officials will consist of a director, who must in all cases be a medical man; inspecting medical officers; and a secretary, who must also be a medical man, except in ports of the fourth class, where he may be a pharmacist. A knowledge of French is indispensable. The vacancies are to be filled up by competition, a tribunal or committee of selection being specially provided for. Preference is to be accorded to naval medical officers and those of the mercantile marine who have had opportunities of seeing cholera, yellow fever, or plague (*peste Levantina*); also to others who have been engaged during epidemics, or who have published works on the subject of hygiene; and lastly, to such as are acquainted with other languages besides French. The establishment of such a service is a step in the right direction, but at present there appear to be no instructions issued as to the precautionary methods to be employed by the different sanitary officers, and it is to be feared that there will be but little result beyond a somewhat more vexatious system of quarantine.

DEATH OF DR. NORMAN CHEVERS.

Dr. Norman Chevers, C.I.E., whose death occurred on the 2nd inst., was secretary to the Medical Board at Calcutta, and subsequently became principal and first physician and professor of medicine of the Medical College of that place, where he lived for about a quarter of a century. He was a member of the Medical Committee appointed by the Secretary of State for India to inquire into Professor Koch's discovery in connexion with the prevalence of cholera. Dr. Chevers entered the Bengal Medical Service in 1848, and retired in 1876 as Deputy Surgeon-General.

SHORTENING OF THE ROUND LIGAMENTS OF THE UTERUS.

Dr. P. Sabil publishes in the *Journal de Médecine de Bordeaux* some very precise directions for finding the round ligaments of the uterus for the purpose of shortening them in cases of prolapsus. He and M. Ricord have made a large number of trials on the dead body, and they have arrived at the conclusion that the Alexander-Adams operation as modified by them will probably prove a valuable means of treating cases of this kind, so as in confirmed cases to supersede the constant wearing of pessaries.

BURMAH.

There are at the present time a very large number of medical officers serving in Upper Burmah with the field force. The principal medical officer at Mandalay is Mr. G. Farrel, C.B., Deputy Surgeon-General; and there are two large field hospitals in Mandalay, one for British and the other for native troops and followers (respectively under the charge of Dr. Corbett, Surgeon-Major, Army Medical Department, and Mr. Peters, M.B., Surgeon-Major, Indian Medical Service), besides other smaller field and other hospitals, [illegible] Corbett and Mr. Peters, who

have been in Burmah since the earliest phase of the guerilla campaign, have rendered excellent service, as also Dr. MacGregor, and Messrs. Elcum, Corkery, and several others. The sickness and mortality that have prevailed have been something terrible, and we hope that the country will by the beginning of next year have so far quieted down as to permit of the return to India of the troops, and their adequate reward by the issue of the necessary *batta*, &c.

TYPHUS IN LARGE TOWNS.

THE appearance of typhus in our large centres of population at the commencement of winter is a matter which always demands the special concern of sanitary authorities, the disease being one which of all others calls for the earliest possible isolation of first attacks. We learn that typhus exists in Liverpool, but not as yet to an exceptional extent. It is also somewhat prevalent in Leeds, where the neighbourhood of Marsh-lane is affected.

FOREIGN UNIVERSITY INTELLIGENCE.

Innsbruck.—Dr. Eduard Lange, Extraordinary Professor of Skin Diseases and Syphilis, has been made Ordinary Professor.

Santiago, Chili.—It is probable that Professor E. von Fleischl, assistant in the Physiological Institute in Vienna, will accept the vacant Professorship of Physiology.

Basle.—The death is announced, at the age of forty-four, of Dr. Albert Burckhardt-Merian, Extraordinary Professor of Otology and editor of the *Correspondenzblatt für Schweizer Aerzte*. The deceased was attached to the German army during the Franco-German war, and made some valuable reports on the subject of military hygiene, which have been of great use in the organisation of the Swiss army.

THE *Townsville Herald*, Queensland, announces the death of Dr. Macartney, which took place there on Oct. 1st, after a short illness, and only ten months after his marriage. Dr. Macartney was an old Belfast student, and before he left for Queensland he did temporary duty for Dr. Dunlop, Holywood. He was considered by the members of his profession as a man of more than average ability, and the older practitioners anticipated that he would have had a distinguished future. Dr. Macartney was taken ill about five o'clock, and before ten he had breathed his last. Medical assistance having been sent for, Dr. Van Someren arrived shortly before his death, but his skill was unavailing.

WE learn, from its publication in the *Bombay Gazette*, that the students of the Grant Medical College have presented a petition to the University of Bombay, praying that the designation conferred by this body be altered from Licentiate in Medicine and Surgery to Bachelor of Medicine, the reasons assigned being that it is likely to be "confounded with a mere licence conferred by colleges and licensing bodies."

A MEETING of delegates from the various medical schools in London was held at the Middlesex Hospital on Wednesday, the 8th inst., to consider the desirability of granting degrees to London medical students. After a discussion, Mr. F. Treves, acting secretary, was desired to summon another meeting at an early date in next year.

DR. HAROLD B. DIXON, M.A., F.R.S., Fellow of Balliol College, Oxford, has been appointed Professor of Chemistry and Director of the Chemical Laboratories in Owens College, Manchester, in succession to [illegible] M.P.

DR. J. S. MACKAY, senior surgeon to the Rio Tinto Mining Company, Spain, has received from the Spanish Government the Grand Cross of Isabel for his bravery and his services during the terrible cholera epidemic. The cross is a Maltese one, with a groundwork of white enamel on both sides. On one side is the inscription, "Por Isabel la Catolica"; on the other, "Por lealtad acrisolada"—for pure bravery.

WE regret to record the death, on the 4th inst., of Dr. Alfred Wiltshire, at the early age of forty-seven. We hope to publish in an early issue an obituary notice of the deceased, who held several professional appointments and was a voluminous contributor to various medical and scientific publications.

DR. THOMAS BUZZARD, F.R.C.P.L., has been elected a member of the Royal Institution of Great Britain.

PROFESSOR PASTEUR is staying at Bordighera for his health, which has somewhat suffered of late.

THE FELLOWS, MEMBERS, AND COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

HISTORY AND INFERENCE.

IN an article which appeared in our issue of Oct. 30th we gave a brief historical account of the various Companies or Gilds which preceded the institution of the present College of Surgeons, and traced some of the changes which had in the course of two or three centuries been introduced into their constitution and modes of government. Up to the beginning of the seventeenth century the government of the Barbers' Company and of the Company of Barbers and Surgeons, successively was, like that of other craft-gilds, practically in the hands of the whole commonalty. There were regular assemblies of the gild-men to elect the President and Wardens, to enact bye-laws, and transact the business of the Gild. The Charters embodying the constitution of all the Companies were confirmed at the beginning of every new reign up to the time of Elizabeth. But on the accession of James I. important changes were introduced. Instead of confirming the old Charters by *Inspeximuses*, this Sovereign granted a series of new Charters to the more important of the Companies. By these Charters the ancient mode of election by the commonalty was superseded; the Court of Assistants became self-elective and held office for life, and the government of the Gild and the exercise of the franchise were transferred from the community to the Master, Wardens, and Court of Assistants. By an Act of Parliament passed in 1604 (2nd James I.) the members of the Court of Assistants of the United Company of Barbers and Surgeons were, in accordance with the new practice, for the first time elected for life, and the Master was chosen from and by the Assistants. The Act of Parliament of 1745, which separated the Barbers and the Surgeons, not only confirmed these monopolies, but vested solely in the Master, Wardens, and Assistants the power to make or abrogate such bye-laws and ordinances as might seem requisite. In the face of this it is absurd to represent that some Members of the present College of Surgeons pretend to base their claim to elect the Council on the Charter of Charles I. Even if this Charter had conferred on ordinary members of the Company the right to elect the governing body, the Charter was itself superseded by the Act of Parliament of 1745. This Act did not, however, deprive the Members of the old Company of Surgeons from the right of meeting in general court on important occasions. It is important to bear this in mind, for though this right was, for some reason, not exercised after the year 1784, the fact of its existence had an important influence on subsequent events. It is probable, for example, that if the Master and Court of Assistants of the late Company of Surgeons had had the [illegible] candour to confer with the Members, the [illegible] have come to such an ignoble end, and [illegible] present

College of Surgeons would have been honourably established by Act of Parliament, instead of having to resort to questionable expedients in order to obtain a Charter. Had an Act been fairly and honestly obtained, it is certain that those constitutional anomalies and abuses which the present agitation for reform is seeking to remove would have been unknown.

The circumstances which led to the dissolution of the old Company and the establishment of the present College, were briefly as follows: By the Act of 1745 it was enacted that the Master and at least one of the Governors should be present at every Court, with one or two ordinary Assistants, in order to constitute a quorum. It happened at the meeting to be held on July 7th, 1796, that in consequence of the death of one Governor and the serious illness of the other no legal Court was possible. Notwithstanding this, the Master and some Assistants determined on proceeding to business. This rash action proved fatal to the Corporation. The opinion of counsel was taken, and there was no doubt that the Corporation was destroyed by the illegal construction of the last court. In the following year a Bill was brought before Parliament, at the instigation of the Court of Assistants, to indemnify the Court and to legalise its acts, as well as to procure the re-establishment of the Corporation under the name of a College. This Bill had passed through the House of Commons, and had been twice read in the House of Lords, before the Members of the Corporation were aware of its purport. A petition in opposition to the Bill was at once prepared, and presented to the House of Lords. This petition set forth that the Bill had been drawn up without the knowledge or sanction of the members of the late Company, who had not been convened to consider it. It further declared that the Master, Wardens, and Assistants, without the knowledge or consent of the Company, had alienated the property of the Company; made purchases greatly beyond the extent allowed by law; and been guilty of gross maladministration: that they had not taken one material step for the public good or the advancement of the science of surgery; that a certain number of the Court of Assistants had, as examiners, received for their private use a large share of the revenue of the Company; that if the Bill were to become law those persons who had been guilty of this maladministration would acquire absolute supervisal and control over the members and their affairs; that the ancient privileges of members would be annihilated, and their right of meeting in a General Court would be taken away; and that the Court of Assistants would be able to oblige members to swear to the observance of such laws as the Court might make, although the members themselves would have no voice in the making of these laws, and no choice in the appointment of those who should make them. The result was that the Bill was thrown out in the last stage. General indignation ensued on the disclosure of the gross and culpable mismanagement. Lord Thurlow, who took up the cause of those members who petitioned against the Bill, said: "The petitioners against this Bill have great reason to complain. Their privileges have been violated; and even their property has been invaded. They have been too long trampled under foot; and, however grating it may be to the ears of some people, they have the strongest title in the world to have their complaints heard with patience and attention." A member of the Corporation, writing in 1797, immediately after the rejection of the Bill, said: "A Bill has been brought into Parliament, and was nearly carried through both Houses, calculated to give a despotic power over the Surgeon's Company to a junto, self-nominated, consisting of an insignificant number, who fill up all vacancies in their own body; so that you are to obey laws, made by persons who have an interest distinct from your own; laws, made by a legislative body, in which you have no representation. This is a degradation of your profession, and even of your species; it is a daring attack on the free principles of the British Constitution."

As bearing upon the present demand of Members of the College for the franchise, it should be stated that one of the reasons which led to the rejection of the Bill by the House of Lords was the determination of its promoters to exclude ordinary Members from any share in the management of the affairs of the College. A noble and learned lord asked one of the principal supporters of the Bill what objection he had to allow Members of the Corporation at large a share in the management of their own affairs. The answer was, "Some of them are ignorant, my Lord." To which his Lordship replied, "The more shame to you to let loose a set of ignorant fellows." This was, be it remembered, in the year 1797, and it is worthy of remark that after a lapse of nearly ninety years Mr. Erichsen, in his recent pamphlet against admission of Members to the franchise, reproduces the spirit and intention of this objection, though not the identical words.

But in spite of the rejection of the Bill by the House of Lords the discredited Court of Assistants of the defunct and dissolved Corporation did not despair; they continued to admit persons under letters testimonial, and though low in reputation and in funds, agreed on Dec. 13th, 1799, by a *unanimous* vote, to accept the charge of Hunter's Museum, for which Parliament had six months before voted a sum of £15,000. The next step followed as a matter of course: the Court of Assistants had now no difficulty, by the aid of courtly intrigue, in satisfying George III. that it was impossible to discharge its trust without some method of replenishing its finances. What Parliament had refused the King was easily prevailed upon to grant, and thus in the month of March, 1800, the College of Surgeons was established by a Royal Charter, which sanctioned most of the obnoxious provisions contained in the Bill rejected by the House of Lords. The course of events since that time is more or less correctly known. But there is one fact that stands out conspicuously in the negotiations which preceded and led up to the establishment of the College, and that is, that Parliament refused to pass a Bill which excluded Members of the College from a share in its government. Consequently, though it is true that Members have no legal "right" to the franchise by the Charter of 1800, they have at least a tacit moral claim, which the present Council should frankly recognise, and thus do what it can to purge it of the taint which has hitherto vitiated the constitution of the College.

THE PROFESSION AND THE COLLEGES.

MEETING OF THE METROPOLITAN COUNTIES BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

A SPECIAL meeting of the Metropolitan Counties Branch of the British Medical Association was held at the Royal School of Mines on Friday evening, December 3rd, Dr. Bristowe, F.R.S., President of the Branch, in the chair. The meeting had been specially convened by the Council in compliance with the requisition signed by twenty members, to consider the exclusion of the Apothecaries' Society from the Conjoint Examining Board, and the representation of Members and Licentiates upon the Councils of the Colleges of Surgeons and Physicians. There were not more than seventy members present.

At the commencement of the proceedings a protest was handed in against the introduction on the agenda of other business than that for which the meeting was specially summoned; and it was decided to postpone that business until the close of the meeting.

Dr. MORTON, in the absence of Dr. Danford Thomas, moved the first resolution: "That this meeting is of opinion that the exclusion of the Apothecaries' Society from participation in the Conjoint Examining Board of England and Wales will, under the provisions of the recent Medical Act, 1886, lead to one or other of the following consequences, either of which are equally to be deplored in the interests of the public and of the profession, and especially of the general practitioners of England and Wales: (*a*) Extinction of the Apothecaries' Society in the highly improbable, if not impossible, case of their not receiving the legal powers which the Act contemplates, to appoint surgical examiners recognised by law—a result which would be disastrous to the whole profession and to the public, seeing that the powers of the Apothecaries Act alone avail to protect the profession against the practice of a large body of unqualified practitioners, and especially of visiting and prescribing chemists; or (*b*) in case the Apothecaries' Society receive such powers of giving a surgical examination and surgical licence, legally registrable, the creation of a new class of surgical and medical practitioners throughout England and Wales, contrary to the intention of the Legislature and the wishes of the profession, [illegible] to medical and surgical titles,

who would compete on a lower grade with the existing Members of the College of Surgeons and the Licentiates of the College of Physicians." Dr. Morton said that the present was a critical period in the history of the profession, the new generation of medical men aspiring to take a share in the government of their Colleges, of which they formed a part, and striving to obtain reasonable facilities for obtaining medical degrees in London. The Colleges had treated the Apothecaries' Society with scant courtesy in delaying to reply to the application of the Society, and in returning a negative answer in the face of a resolution passed at the meeting of the Members of the College of Surgeons on Nov. 4th. The Apothecaries' Society may not be a very dignified body, but it has a respectable and useful history, and at one time the "apothecary" took precedence of the "barber-surgeon." During the whole of the present century the work done by the Society would compare favourably with that done by the College of Surgeons. If the Society were extinguished, there would go with it valuable powers which it alone possessed for repressing illegal practice in this country. It is, however, very unlikely that the Society will submit to extinction, for the Act especially provides for its seeking assistance to grant a full diploma, with power to appeal to the Privy Council if such a privilege is denied it by the General Medical Council. The result would be the creation of another lower order (No, no!) of practitioners; at any rate the admission of candidates at lower fees, with a consequent loss of dignity to the profession. Such a result is said to be deliberately contemplated by the Colleges, which desire to see the establishment of a grade of *officiers de santé;* and the poor would suffer unless some such provision were made to ensure them medical aid; but the true way of meeting this question was the extension of the provident dispensary system.

Mr. VERDON seconded the motion, the subject being one, he said, that affects the welfare of a large body of practitioners, and to be considered from a practical and common-sense point of view. If the Colleges adhere to their decision, then the Apothecaries' Society will either undergo extinction or rejuvenescence. In the first case the Act of 1815, with its important penal clause, would perish with it; but it is very unlikely that the Apothecaries' Society will die. It is showing no signs of decrepitude, and the effect will be the creation of a new order of practitioners who will compete successfully with the L.R.C.P. and M.R.C.S., and lead to a divided profession.

Dr. PARAMORE supported the resolution, characterising the treatment of the Society by the Colleges as an act of base ingratitude.

Mr. G. BROWN said that the result of the action of the Colleges would not be the extinction of the Society; and he strongly deprecated the introduction of the words "lower grade" into the resolution, for in his personal experience the examination at the Hall was better than that at the College of Surgeons.

The words "lower grade" were, by consent, struck out of the resolution.

Mr. WALLIS MASON asked that the resolution should be passed with great force. The Councils of the Colleges must be influenced, but they will require force applied from all sides to compel them to yield. He urged that members of Parliament should be approached, so that pressure might be brought to bear through the Government.

The resolution was then put and carried, 39 voting for and 5 against it.

Mr. T. HOLMES moved the second resolution: "That, seeing that the Royal College of Physicians and the Royal College of Surgeons of England are entrusted with the regulation of the examinations and status, and with the protection of the interests, of the general practitioners throughout England and Wales, and that under the Medical Act of 1886 their powers and monopoly in this respect are greatly strengthened, it is just and important that the Members of the College of Surgeons and the Licentiates of the College of Physicians respectively should be duly represented in the Councils of these Colleges, and should be admitted to a rightful share in the administration of their own affairs in relation to the government of these Colleges." Mr. Holmes said that it no longer admitted of argument that Members of the College of Surgeons are entitled by every consideration of justice and public policy to a voice in the management of their own College. If the Members are satisfied that the affairs of that wealthy corporation should be managed without their [illegible] if they had no interest at all in it, there was no more to be said; but if they were dissatisfied with such a state of things, the remedy was in their own hands, and they were sure to succeed. He did not know what might be the case at the College of Physicians, but he supposed the same line of argument would apply to it. The management of that body does not appear to have gained the admiration of the profession, and it seemed only reasonable that its Licentiates should share in the work.

Mr. GUBB seconded the motion, and said that the Licentiates of the College of Physicians had the right to speak—at any rate in affairs in which they are interested. The College had only taken up the work of licensing general practitioners for the past twenty years, and had done so with the narrowest restrictions.

Mr. STOKER pointed out that the franchise in question at the Colleges was an educational one, and that any attempt to endow Members with it as well as Fellows would be to lower the educational standard.

Dr. COUPLAND appealed to the mover and seconder to divide the resolution respecting the two Colleges, but this being declined, he moved that the part of the resolution affecting the College of Surgeons be taken separately from that affecting the College of Physicians.

The motion was seconded by Dr. DOWSE, and negatived by 29 votes to 14.

The original resolution was then put, and carried by 39 to 1.

Respecting the remaining resolutions on the agenda, a letter was read from the solicitors to the Association pointing out that the meeting had no power to take action upon resolutions passed, but that such action must be taken by the Council. The final resolutions were therefore recast by Mr. HART, who moved their adoption, requesting the Council to prepare a petition, and to ask the Colleges to receive a deputation, upon the subject of the two resolutions. Also that the resolutions be communicated to the Branches of the Association, and that the Council appoint a committee consisting of its own members, together with a number nominated at the meeting.

METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

A CONFERENCE of medical and lay gentlemen, with a few ladies, was held on Tuesday last at the Society of Arts, John-street, Adelphi, Sir Andrew Clark, Bart., in the chair.

The CHAIRMAN, in opening the meeting, said the object of the conference was to ascertain the views of the medical and lay public on the principles stated in the resolutions to be submitted to the meeting. For his own part, he confessed that he had not yet come to any definite conclusions; therefore he felt qualified, in his character of chairman, to listen patiently to the suggestions that might arise for and against the objects of the Metropolitan Provident Medical Association.

Mr. TIMOTHY HOLMES made a lengthy speech, and endeavoured to place before the meeting the *pros* and *cons* in connexion with the movement, which had originated as long as thirty years ago. It was admitted that the movement, though successful in some districts, was, on the whole, not gaining the ground which it was hoped it would have done. The principle on which the Association worked was that of insurance as in life and fire offices. The out-patient departments of the hospitals were abused by people who could well afford to pay something for medical advice. The provident movement, if successful, would diminish the expenditure at hospitals by relieving the out-patient department. He thought that from the point of view of the poor, of the general public, of the hospitals, of the medical practitioners, and of the medical teaching and science, the Metropolitan Provident Medical Association, so far as its principle was concerned, would prove of great advantage. Some such method of dealing with this great question was absolutely necessary. He considered that the Association should be managed by the public, and not by private enterprise. The dispensaries should be affiliated to the hospitals, which should be used as the [illegible] for the poor. It was difficult, indeed, to say [illegible] Members of the Association were to be. An [illegible] limit was probably the best method of [illegible] member-

ship. He proposed:—"That in the opinion of this meeting the future medical attendance on the poorer classes ought to be conducted on the principle of sick assurance."

Mr. LUSHINGTON, treasurer of Guy's Hospital, seconded the resolution. He thought that with proper safeguards and precautions the Association, or some movement of the kind, would prove of great utility in solving the difficult problem. When people paid for anything, were it medical advice or otherwise, it created and established within them a feeling of independence and manliness. In cases of extreme poverty the small payments were not exacted at Guy's Hospital.

Dr. PARAMORE did not approve of the methods of the Metropolitan Association. He would support the principle of sick assurance, but rather in the manner proposed by Dr. Sheen at Cardiff.

Mr. F. B. JESSETT gave an account of a successful venture on the principle of sick assurance that occurred in one of the London suburbs.

Dr. WALTER SMITH thought that there should be a wages limit.

Mr. G. BROWN and Dr. R. J. LEE joined in the discussion.

The resolution was put to the meeting and carried unanimously.

Mr. W. BOUSFIELD, chairman of the Association, next moved the second resolution, and explained the grounds of the necessity for drawing the attention of the governing bodies of hospitals to the abuse of the out-patient department.

The resolution was seconded by Mr. NELSON HARDY, and carried unanimously. It ran as follows: "That the attention of the governing bodies of hospitals and other public authorities be called to the necessity for some check on the indiscriminate provision of medical treatment at hospitals and dispensaries."

Sir T. SPENCER WELLS, Bart., proposed the appointment of a committee "for the purpose of reporting on the subject of assurance as applied to the treatment of the sick."

Mr. WILSON seconded the motion, which was adopted, and a small committee was elected with power to add to their number.

REPORT ON SANITARY MEASURES IN INDIA IN 1884-5,

TOGETHER WITH MISCELLANEOUS INFORMATION UP TO JUNE, 1886. (VOL. XVIII.)

WE have already brought under the notice of our readers much of the information contained in this volume, in our special articles on the Reports of the Sanitary Commissioner with the Government of India, and of the Army Medical Department.[1] We shall therefore now confine our remarks to a few points which from various causes did not previously come under observation. One of the most important of these is the subject of the measures taken during the year to improve the sanitary condition of Calcutta, as shown in the reports of the Calcutta municipality by Mr. Harrison, and of Dr. O'Brien, the health officer. The death-rate of the year 1884 was for the town of Calcutta 30·5, and for the suburbs 45·2 per 1000 of the population, the former being higher than in any of the preceding five, and the latter than in any of the preceding four, years. The increase was chiefly due to cholera, which prevailed in the form of a severe epidemic in the months of March, April, and May, and was the cause in the course of the year of 5·2 deaths per 1000 in the town and 9·6 in the suburbs. The deaths by small-pox were also much in excess of the average. The most fatal class of diseases was fevers, by which the mortality in the town was 8·3 and in the suburbs 15·4 per 1000 of their respective populations. "The higher rate of mortality was confined to the first two quarters of the year. The total number of deaths registered during this period was 7301. In the two later quarters the number fell to 5055. The figures of the first period exceed the decennial mortality by 915, while those of the second fall short by 848." Whether it was in consequence of the high death-rate in the first half of the year, or of the course taken by the Lieutenant-Governor in the appointment of a special committee to report upon the cleansing and conservancy of the town, there seems to have been increased energy in carrying out sanitary improvements. These consisted chiefly in an augmented supply of water filtered and unfiltered, the former for drinking and the latter for the purposes of road-watering and of flushing; completion of the sewerage of the town; improvement of privies and latrines; filling up foul tanks and wells, and construction of bathing platforms; improvement and subsoil drainage of bustees, and surface conservancy; for the latter purpose an increase of 50 per cent. was made to the establishment, and the bustee grant of 80,000 rupees which had been sanctioned was doubled. There still remains much to be done in the way of sanitary improvements, but a very satisfactory impetus seems to have been given to the subject. With regard to Hastings ward, which "maintains its unenviable reputation as the worst ward in the town," the health officer states: "It is satisfactory to be able to report that the necessary funds have been allotted in the Budget of the current year for the thorough drainage of this ward. With an efficient system of well-flushed underground sewers, and an increase in the supply of pure drinking-water, it ought to become a very healthy ward."

The mortality in Madras is shown by the report of the municipality to have been 39·8 per 1000 of the population, or about 20 per cent. higher than in 1883. This great increase was due chiefly to small-pox and cholera: the former prevailed as an epidemic from the beginning of the year till the end of June, and the latter with great virulence in August and September. Sanitary work appears to have been carried on satisfactorily during the year, but there is no report by the health officer as to its results, nor is any information given on the subject of further requirements in this important branch.

We have already noticed the sanitary condition of the municipality of Bombay (*vide* THE LANCET Jan. 16th, 1886) as detailed in the annual report by Surgeon Davidson, the acting health officer. From the report of the municipal commissioner, it appears that important works for the improvement of the water-supply and for the more efficient drainage of the town have been so far successfully carried out, and their completion is in progress. But there seems to be some difficulty with regard to connecting the house drains with the sewers, as it had not been determined "whether the necessary house pipes and fittings should be paid by the municipality, as at first determined, or by the house-owners." In connexion with the question of the disposal of the sewage, it is mentioned "that the construction of a chamber within which the offensive matters raised by the shred-lifter [at the Love Grove pumping-station] may be incinerated is being pushed on and will soon be complete."

THE LIVERPOOL HOSPITAL FOR WOMEN.

REPORT OF THE INQUIRY COMMITTEE APPOINTED BY THE LIVERPOOL MEDICAL INSTITUTION.

HISTORY OF THE APPOINTMENT OF THE COMMITTEE.

THE operative procedures included under the term "abdominal section" having risen at the Hospital for Women, Shaw-street, Liverpool, from 86 in the year 1884 to 166 in the year 1885, this remarkable increase was brought before the notice of the Liverpool Medical Institution at a largely attended meeting, held on February 4th, 1886. At this meeting a Committee was appointed to inquire into the matter, and the medical staff of the Hospital for Women then present took an active part in the discussion and voted for the proposed Committee.

The resolution under which the Committee was appointed stated that "In view of the large and increasing number of cases of abdominal section in the Hospital for Women in this city, as shown by the annual Medical Report for the year 1884-85, this meeting is of opinion that a Special Committee be appointed for the purpose of investigating the grave question of practice and ethics involved in the performance of these operations, and to report to a future meeting."

The Committee consisted of the President of the Medical Institution (Dr. Nevins, Consulting Physician, Stanley Hospital, Kirkdale, and Consulting Surgeon, Liverpool Eye and Ear Infirmary); three former Presidents (Mr. Bickersteth, Senior Surgeon, Royal Infirmary; Dr. Cameron, Senior Physician, Royal Southern Hospital; Dr. Waters, Senior Physician, Royal Infirmary); one present and three former Vice-Presidents (Dr. Alexander, Surgeon, Liverpool Workhouse Hospital; Mr. Mitchell Banks, Surgeon, Royal Infirmary; Dr. Macfie Campbell, Consulting Surgeon, Northern Hospital; Dr. J. H. Wilson, Consulting Physician, Lying-in-Hospital). At a subsequent period it was deemed right that the medical officers of the Hospital for Women should each, if they wished, send a representative to the Committee to watch their interests. Mr. Damer Harrisson, Surgeon to the Northern Hospital, and Dr. Barron, Medical Tutor to the Royal Infirmary, were nominated on the part of Drs. Burton and Lupton, and were placed on the Committee. Dr. Imlach did not nominate any representative. After a short period of service [illegible] resigned his seat.

Before proceeding to their report, the Committee regret very much that it has been so long delayed. They wish it to be known, however, that this has not been due to any remissness on their part. During the early part of the year they felt that it would have been ungenerous to have pursued their inquiries during the serious illness of Dr. Imlach, one of the medical staff of the Hospital for Women; while during the summer their hands were tied by the fact that a civil trial, Casey v. Imlach, was pending, before the conclusion of which any investigation into the questions affecting that trial by any private body would clearly have been improper. Even after the conclusion of that trial, great delay (in spite of frequent applications to the Hospital Committee) was experienced in getting the reports of cases from the Hospital, so that the more important labours of the Committee may be said to have practically commenced only about two months ago.

MODE OF CONDUCTING THE INQUIRY.

The Committee have devoted a great deal of time and labour to the inquiry with which they were charged. They have met on twenty occasions, the sittings lasting from two to four hours. Their plan of operations has been as follows:—

1. The Lay Committee of the Hospital for Women requested each of the medical officers of the institution to produce reports of all the cases of abdominal section done by him during the year 1885. These reports were laid before the Medical Board of the hospital, who made comments upon them, and who visited many of the patients at their own homes, with the view of ascertaining their condition some time after operation. The reports, with the annotations of the Medical Board appended to them in writing, then came before the Inquiry Committee. Each report was read aloud by one of the members, and notes were taken by the others. After the reading of the report, the Committee discussed the case, and adjudicated upon it, as far as could be done by the written statements concerning it.

2. The Committee invited the medical practitioners in Liverpool and the neighbourhood to give them any information about the subsequent progress of the cases which had been operated upon in the Shaw-street Hospital, but which had been under their care before or after operation. The letters and communications received from these gentlemen were read and considered in connexion with the hospital reports of the cases mentioned.

3. The Committee personally visited at their own houses between forty and fifty of the patients who had been operated upon, selecting, as a general rule, cases where there was a discrepancy between the statements of the original report and the annotations of the Medical Board or the letters from practitioners, or cases in which the information seemed incomplete.

4. The Committee finally examined certain specimens of ovaries and Fallopian tubes removed by Dr. Imlach, and voluntarily laid by him before the Committee for pathological investigation.

5. The first step taken by the Committee was to appoint a deputation, composed of Dr. Cameron and Dr. Alexander, to visit the Hospital for Women, to look into the operation registers and to examine the lady superintendent and nurses upon such points as might seem to them to bear upon the inquiry. The Committee of the Hospital at once agreed to receive the deputation, appointing Mr. Bushby, the President, and Mr. Job to meet them. At the same time, they courteously expressed their desire to promote in every way the object of the Inquiry Committee.

The principal subject of inquiry was whether the patients were duly and fully informed of the nature and probable consequences of the operations proposed. The lady superintendent and the nurses stated that they were always most completely informed upon every point. The deputation, however, reported to the Inquiry Committee that the impression which they had received from their interview was that, whatever might have been the intention of the nursing staff, they had not in reality conveyed to the patients such information as to the character and results of the operations as could alone be considered sufficient.

CLASSIFICATION OF OPERATIONS.

With regard to the various operations involving abdominal sections, the Committee have deemed it best to consider each operation by itself. In their judgment these operations have been performed skilfully and with due attention to all proper surgical precautions, while the patients universally stated that they had received every attention and kindness while in the hospital.

Of the whole number of abdominal sections for removal of the uterine appendages, eighty-five were performed by Dr. Imlach, sixteen by Dr. Burton, and five by Dr. Lupton.

Ovariotomy, meaning thereby the removal of large cysts or tumours of the ovaries.—This operation is one the expediency of which is universally recognised, and the Committee are of opinion that the cases submitted to this procedure were fit and proper cases for it, and that the operations were done satisfactorily and successfully.

Exploratory Incisions into the Abdomen.—Considering the great difficulty of diagnosing many morbid conditions in the pelvis and abdomen, it is admitted that in certain instances an incision may be made into the abdomen for exploratory purposes with so little risk as to warrant this proceeding, enabling the operator, as it does, to take further action if practicable, or to leave matters as they are if such action is impossible. The Committee therefore think that the few operations of this character done at the Hospital for Women were justifiable.

Oophorraphy, or the Replacement and Fixation of Prolapsed Ovaries.—Concerning this operation, the number of cases reported was not sufficient to enable the Committee to express any strong opinion either for or against it. But while they do not wish to regard it in the light of an unwarrantable operation, they find that the relief afforded by it to the patients was by no means clear and decided. This, combined with the danger attached to all abdominal sections and the uncertainty as to whether the ovaries will retain the position in which they are fixed after replacement, constitute serious objections to anything like a frequent use of this proceeding.

Removal of the Ovaries and Fallopian Tubes ("Uterine Appendages").—As it is with regard to this operation that the greatest controversy has occurred, the Committee have given to it their most serious consideration. They are quite aware that it is an operation which is admitted into the category of legitimate and justifiable surgical proceedings, applicable to certain cases, and they wish it to be thoroughly understood that they are not reviewing the operation as such [illegible] the way in which it has been employed at the Hospital for Women and the subsequent results to the patients after the lapse of a period of time sufficient to enable a correct appreciation of the value of the operation to be made.

RESULTS OF THIS LAST OPERATION.

Danger to Life.—Out of 106 patients subjected to removal of ovaries and tubes, 9 died, being a mortality of between 8 and 9 per cent. If the morbid conditions for which this operation is done are such as to make life miserable, and if the results of the operation are found to be completely and thoroughly satisfactory from a curative point of view, then this mortality cannot be considered excessive, in view of the fact that such operations become less and less fatal in course of time from the discovery of new appliances and from increased skill on the part of individual operators. If, on the other hand, the operation is done for comparatively trivial affections, or for conditions which might be remedied in a reasonable time without resorting to operation, and if the results are afterwards found to be far from certain curatively, then a mortality of 8 or 9 per cent. is a serious objection to the operation done under these circumstances.

Sterility.—The operation, it must be borne in mind, when both ovaries are removed, inevitably produces sterility. Out of 92 patients on whom this operation was done in the Hospital for Women, 59 were between twenty and thirty years of age, while 7 were only from seventeen to twenty years old. It may be said that the ovaries removed were already useless for child-bearing purposes, but the Committee consider that very great difficulty exists in making certain of this fact, either before or even at the time of operation. Under these circumstances the operator should take especial precaution invariably to inform the relatives of an unmarried woman, or the husband of a married woman, as well as the patient herself, that she will in future be sterile.

Loss of Sexual Feelings and of Physical Energy.—With regard to the alteration in voice, abnormal growth of hair, and assumption of masculine appearance which have been stated to follow loss of the ovaries, the Committee have no evidence that such ensue. Concerning the *loss of sexual desire*, however, it was found that a certain number of patients stated that they had not perceived any difference after the operation; from a large majority no information could be obtained; while out of those upon whose statements reliance could be placed, a considerable proportion averred that they had suffered a distinct loss of sexual feeling, to such an extent as to cause serious domestic unhappiness in not a few instances. Furthermore, certain of these patients also complained of such a loss of physical energy and spirit as prevented them discharging their ordinary household or other duties as before operation.

Danger of Hernia following the Operation.—Out of 106 cases of abdominal section it was found, as a matter of fact, that in 15 instances a hernia resulted at the line of incision, and of these 13 occurred amongst the 106 removals of the ovaries and Fallopian tubes. This, however, does not represent the full percentage, because a large number of the 106 cases could not be traced, and the 15 cases of hernia were confined to those which could.

Actual Benefit to the Patients.—The Committee have found that many of the patients operated on have received distinct and probably permanent benefit, and to such the operation has naturally been a great boon. On the other hand, in very nearly an equally large number, the relief to suffering afforded by the operation did not seem to the Committee to have been of a decided or lasting character, while to some the operation has been positively injurious.

In view of the above facts, the Committee wish to point out that the removal of the ovaries and Fallopian tubes is an operation which cannot be considered purely from a surgical aspect, but that it has, also, a certain ethical or moral element in it which cannot be put aside. For whether it be regarded as a mere sentimental objection or not, the removal of the organs which are characteristic of sex is, and always will be, viewed by the public and the medical profession with great misgiving. In consequence, such an operation should only be performed after the most careful consideration. As a result of their investigation, the Committee are of opinion, considering the various risks attending the operation of removal of the ovaries and Fallopian tubes and the uncertain nature of the results, that at the Hospital for Women sufficient care and discrimination have not been exercised in the selection of cases for operation, and that in many instances the gravity of the symptoms was not such as to have justified an abdominal section of any kind. It appeared to the Committee that frequently a sufficient trial of rest in hospital had not been given before operation, seeing that this most important feature in treatment cannot be obtained by poor women, who are merely attending as dispensary patients, and who at their homes are endeavouring to pursue their usual fatiguing duties.

The Committee regret that from a scientific point of view they are unable to give any very definite assistance to the medical profession in judging of the class of cases appropriate for the operation under consideration, in advance of what is already known and admitted.

Pelvic Hæmatocele.—On one point they feel decided—viz., that in ordinary cases of pelvic hæmatocele it is not to be recommended.

Bleeding Myoma.—They also note the fact that a large number of the operations were done in the Shaw-street Hospital under the diagnosis of "bleeding myoma." But the reports signally fail in giving any description of the size and character of the myomata, or of the state of the uterus when the abdomen was opened at the time of operation. Moreover, there are no definite records of a character likely to be useful to the profession, as to the subsequent shrinkage of the said tumours; while certain patients reported as "cured" have stated that they still suffered from hæmorrhage. Indeed, the Committee have found serious discrepancies between the statements made by one of the operators and the condition of matters found by the Medical Board and by themselves. But they are willing to believe that such discrepancies were often due to the fact that the patients had been reported upon rather early by the operator, while they were seen at later periods by the members of the Medical Board and Inquiry Committee appointed to visit them.

RECOMMENDATIONS.

Consultations.—With a view to the more prudent consideration of the cases demanding operation, the Inquiry Committee desire to urge upon the authorities of the Women's Hospital that a more frequent use of consultations by the medical staff be made for the future. They are distinctly of opinion that consultations in the proper sense of the word have been too much neglected by one of the operators, and they suggest

that Rule 39, which now runs: "No operation of a dangerous character shall be performed in the hospital without a consultation between one of the medical officers for in-patients or one of the consulting medical officers and the operator," should run: "No operation of a dangerous character, or that involves abdominal section, shall be performed (except in cases of extreme emergency) without previously summoning a consultation of the consulting and acting surgeons for in-patients."

Previous Information to the Patients.—The Committee are also of opinion that the medical staff should use more care fully to apprise the patients of the nature of the operations about to be performed, and their possible results. The patients examined by the Committee very generally denied that sufficient information—or, indeed, any information at all—was given to them as to what was proposed to be done to them.

Longer Retention in Hospital after Operation.—In view of the large proportion of cases of hernia occurring after abdominal section, especially after removal of the ovaries and Fallopian tubes, and of the fact ascertained by the Committee that many operation-patients, after being discharged from the hospital as "cured," had to remain in bed for considerable periods in their own homes, the Committee recommend that patients should in future be retained for a longer period in hospital after operation than has hitherto been the case.

In conclusion, the Committee are very strongly of opinion that the diseases which alone should be treated in the Hospital for Women should be those occurring in the female genito-urinary organs. Such operations as those for the cure of rupture, for the removal of the spleen, for cancer of the breast, or for opening the bowels, in disease of the rectum (which, with others of a similar character to the number of twenty-one, were performed in 1885 in the Shaw-street Hospital) are entirely unsuited for such a hospital, and should be relegated to a general surgical hospital. If such operations as those mentioned are done in a hospital for special gynæcological work, then the public are called upon to support it under pretexts which are not strictly true, while the presence of cases of general surgery in a hospital where the abdominal cavity is frequently being opened cannot be otherwise than dangerous.

This report was carried unanimously by the Committee on Nov. 27th, 1886, all the members, with one exception, being present.

(Signed) J. BIRKBECK NEVINS, Chairman.
WM. ALEXANDER, Secretary.

WE have received the following letter from Dr. Imlach, with a request for its publication. This letter, he states, he has sent to all subscribers to the Hospital.

To the President of the Hospital for Women.

DEAR SIR,—The conclusion of the whole matter is that I ought to consult with Dr. Grimsdale. That is the keynote and cue of the whole report of the Inquiry Committee, and Dr. Grimsdale's own desire. I accept the position. There is really no reason, beyond a little mutual animosity, why we should not consult. Dr. Grimsdale has admitted that "removal of uterine appendages is a valuable addition to the resources of scientific surgery." Mine is the same contention. He considers the necessity to be rare. But for a long time Dr. Grimsdale has done no hospital work; he will become convinced to the contrary when he sees my cases. The responsibility shall be a joint one.

As to the details of this report, having regard to the peculiar method circumstances, and object of its production [correspondence enclosed], it is fairly satisfactory. The constitution of the Committee has, however, been inexactly described. Its members were nominated by Dr. Grimsdale, who brought their names in his pocket to the meeting. On March 8th Dr. Cameron visited the Hospital for Women as one of the two delegates from the Inquiry Committee. In the presence of yourself and the Vice-President, the case-books, hospital registers, and various memoranda were examined, and the lady superintendent and nursing staff subjected to a severe cross examination. At the next meeting of the Medical Institution he resigned from the Inquiry Committee, declining to serve any longer upon it. Though Mr. Bickersteth did not then formally resign, he has not, I believe, attended a single meeting of the Committee since that date.

It would be a mistake to suppose the acting medical staff was represented on the Committee. On Feb. 17th I wrote from Edinburgh as follows to Dr. Davidson, Professor of Pathology at the Liverpool University:—

"I regret an important engagement prevents my being present at the Medical Institution. My feeling is that the Committee has been irregularly appointed; but, should they see fit, I think your appointment would be very suitable, inasmuch as you were fully acquainted with many of the facts regarding one disputed case."

My object was to get a pathologist upon the Committee; but he declined, stating that he disapproved of the method of appointment of the Committee. It was impossible to be adequately "represented," and I asked no other. To secure fair play, I ought to have been allowed to be present at all the meetings. But when, at a later date, I made a request through you and our secretary to be allowed to appear once before the Committee in order to make a statement and hear any complaint which my competitors might have preferred, it was not granted.

My late colleague, Dr. Lupton, was represented by a gentleman whom he had never seen in his life, and from whom he received not a single communication.

The Committee say that "during the summer their hands were tied by the fact that a civil trial, Casey *v.* Imlach, was pending, before the conclusion of which any investigation into the questions affecting that trial by any private body would clearly have been improper." But with tied hands they issued a circular to the whole medical profession concerning cases treated at our hospital, and asking that replies should be sent in by July 10th. The trial was to come off at the beginning of August, and, in the opinion of my solicitors, this circular was obviously calculated to stir up prejudice against me. And within a week of the appeal for a new trial they publish their opinion that "on *one* point they feel decided—viz., that in ordinary cases of pelvic hæmatocele it (i.e., operation) is not to be recommended."

It is my duty to be respectful to the finding of the Committee, but it is not my whole business to agree with them. They have once more ignored the distinction between extra-peritoneal hæmatocele, or thrombus, as I prefer (with Bernutz) to call it, and intra-peritoneal hæmatocele. If, as I believe, they refer by the term "ordinary" to the former variety, I am certain they are right; there is no object to be gained by an operation, and I have never attempted one.

As to operative treatment, however, to stop indefinite bleeding in the latter form, two short quotations from eminent authorities will convince most people of its propriety, and even urgent necessity.

Sir Spencer Wells says ("Surgical Treatment of Abdominal Tumours," 1885, p. 35):—"An ovarian cyst is seldom dangerous to the life of the patient before it has attained considerable size; whereas a hæmatocele of very moderate extent, and of sudden formation, may be either rapidly fatal or lead to very dangerous symptoms."

Dr. Thorburn, late Physician to the Manchester Infirmary, says ("Diseases of Women," 1895):—"The course of this disease is very varied; death in a very short time often occurs in the intra-peritoneal cases. If post-mortem examinations were more common in private practice than they are, this would be speedily apparent. Inflammation of some indefinite character gets the credit of many of these rapid deaths."

And Bernutz, the most eminent authority upon this subject, quotes a large series of fatal cases in the "Archives de Tocologie," 1884 and 1885.

Of the series of intra-peritoneal hæmatoceles upon which I have operated, in all cases with successful results, Dr. Grimsdale saw only one with me in consultation. It was my second case, and, if he had disapproved, I should certainly have left the patient to her fate. But on November 3rd, 1884, he advised operative treatment; on the next day I performed the operation in his presence, that of his son, Miss Cradock, and the hospital staff, and her perfect recovery speaks for itself. (Vide *British Medical Journal*, May 16th, 1885.)

My late colleague, Mr. Lupton, saw many of my cases in consultation, and assisted at most of the operations. On September 25th he wrote as follows in THE LANCET:—"I desire, from my personal experience, to express my approval of Dr. Imlach's method of treatment of pelvic hæmatocele." Dr. E. T. Davies has assisted at them all, and has expressed his deliberate approval.

Dr. Angus Macdonald, late Obstetric Physician to the Edinburgh Royal Infirmary, wrote as follows:—"Recent experience, especially that of Mr. Lawson Tait and Dr. Imlach, tends to show that this accident (i.e. internal hæmorrhage) is more frequently associated with hæmato-salpinx, or other disease of the uterine appendages, and, therefore, the legitimate object of operation, than we have hitherto supposed." (*Edinburgh Medical Journal*, November, 1885, p. 416.)

And, finally, the question was thoroughly threshed out at the trial, and I won my case.

Of all the operations performed by us the term "justifiable" is only applied to the "exploratory incisions." After many nights they "are unable to give any very definite assistance to the Medical Profession in judging of the class of cases appropriate for the operation under consideration." It is, therefore, with a grave sense of responsibility that I venture, from my experience, to lay down the following propositions:—

1. In simple chronic ovaritis, without adhesions, removal of the organs, or indeed any other operation, is very rarely to be recommended.

2. When this condition is complicated only with peritoneal adhesions, oöphorraphy (in which no parts are removed) is justifiable when pain is persistent, urgent, and disabling. Judged by facts this operation is absolutely devoid of danger.

3. In ovarian abscess operation is imperative.

4. A like rule is applicable when there is an inflammatory or suppurative condition of the Fallopian tubes.

5. The question of sterility is readily and certainly determined at the commencement of an operation; it depends upon the condition of the tubes rather than that of the ovaries. It can also be determined with considerable accuracy in the majority of cases previously to operation.

6. By the time intra-peritoneal hæmatocele is completely diagnosed it is almost too late to operate; but there is also a more chronic and recurrent form.

7. In myoma the question of operation is determined entirely by the persistence of symptoms. The Committee appear to doubt the existence of these tumours, yet dwell upon the persistence of their characteristic symptom. That is taking a double advantage of me. If they had allowed me to appear before them, or asked for further information, this paragraph would not have been written.

8. When peritonitis intervenes in any of these cases, immediate surgical treatment is the only chance of saving life.

I earnestly trust that these eight rules will receive the approbation of the medical profession, with whom I have no wish to be in controversy.

In answer to the ready-made charge of want of discrimination, I have to reply that, through lack of space, the Inquiry Committee have neglected to inform you that I have treated sixty-seven cases of inflammatory disease, sent in with a view to operation, solely by rest, and medical means.

With reference to age it would have been kinder to have mentioned, for example, that two patients, aged nineteen, were treated for large ovarian tumours, and two for double pyosalpinx, a condition of danger not amenable to remedial agents. The discrepancies to which allusion is made may be ascribed to the fact that the inquiry was conducted after the patients, "forty or fifty" in number (at a guess) had been excited by the tale that their nature had been taken away from them.

As to longer retention in hospital, it must be recognised that the advice of the Committee is excellent. We had found out the advantage by ourselves, but it is a difficult matter to carry into practice. During the past twelve months I have kept my patients in hospital on an average for five weeks after operative treatment, with excellent results.

In conclusion, I can only say that I have never performed an operation that I would not, under like conditions, have advised my wife or any relative to undergo, and that I have been as conscientious in my work as any member of the critical Committee, from its president down to its secretary. A vast deal has been made out of the fact that since the illness of my late colleague, Dr. Lupton, I have not carried out Law 39 to the letter. Consultations we must hold; but far more important is our want of a competent and independent pathologist, who should report upon the conditions which had required surgical treatment. The first task I should ask of him would be a report upon the series of specimens I placed before the Inquiry Committee, which they have returned uncriticised. Should these opinions, and this concession, fail to gain acceptance, I must, in honour, tender my resignation. In any case, I trust that your Committee will defend our nursing staff.

Yours obediently,

Dec. 6th. FRANCIS IMLACH.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Isle of Wight Rural District.—The general death-rate for this rural district during 1885 was 15·4 per 1000, or 13·6 if deaths of non-residents be excluded. The death-rate from zymotic diseases was 1·09 per 1000, 10 diphtheria and 4 fever deaths being included. Dr. Groves evidently writes with a feeling that his advice is not heeded as it should be. Thus, referring to the fact that diphtheria raged in Northwood and in Whitwell as an epidemic, he says that one of the most painful features in the sanitary history of the year is that people died of diphtheria who apparently need not have died if the sanitary arrangements of the district had been what they might be. Diphtheria at a certain farm revealed insanitary surroundings which are described as appalling, and yet the dairy produce from this place was sold regularly in Cowes. At Whitwell we read, in connexion with diphtheria, of people drinking water from a well polluted by soakage from a brick drain, of a foul closet, and of overcrowding. At Freshwater the same disease of a fatal character was associated with a closet without water, and stench from an unventilated cesspool. At Porchfield diphtheria was imported from Cowes, and under the same roof as the four sick persons was a dairy, the produce of which was sold in Cowes. Here water was derived from a foul rain-water butt, or from a pond used by cattle in a neighbouring field. At Northwood, where the mortality was great, diphtheria is stated not to have been spread by communication, but the sanitary conditions were bad, and the air was polluted by refuse. In the case of enteric fever, we read of filthy unventilated closets of drinking water subject to fouling by a leaky cesspit, and of an untrapped drain in an affected dairy. So far as the rural district is concerned, the cases were imported, but one came from West Cowes, and another occurred just outside East Cowes. Under these circumstances Dr. Groves may well endeavour to impress upon the sanitary authorities of the island how close is the interdependence between the rural district and the neighbouring towns, and his records supply ample grounds for telling his authority that their mode of procedure in abating nuisances is exceedingly and dangerously slow, and for reminding them that the interests confided to their trust demand more than mere routine administration.

Oldham.—Dr. James Niven, the newly appointed medical officer of health for Oldham, found himself much limited in reporting on the year 1885, except in so far as statistical and other records were at hand. But his preliminary investigations have enabled him to lay down some rules for future work. He finds it necessary to urge increased action to secure modifications of house drainage, and so to prevent the escape of drain air into dwellings. The various results affecting health from defects now existing are fully described; and Dr. Niven is so impressed with the responsibility of landlords in this and similar matters, that he suggests whether the law could not be made to throw upon that class the responsibility of loss arising to occupiers from such causes during at least the first six months of their occupancy. He refers to the fact that the water-supply of the borough is insufficient for all the purposes of the place, and hence arises a custom of using sewage water for condensing purposes, a practice which leads to some of the mill lodges becoming a source of discomfort and danger. The Westhulme infectious hospital did excellent work during the year, 132 patients being received into it; of these ninety were scarlet fever and thirty typhoid fever. The internal management of the institution is highly spoken of. A long list of excellent sanitary work is appended, and amongst other matters we find that 5843 articles were disinfected; the same process, together with cleansing, being applied to 797 rooms and 275 houses. Oldham possesses an excellent organisation for these purposes. The birth-rate for 1885 was 35·5 and the death-rate 22·0 per 1000.

SIR ANDREW WALKER, BART., has announced his intention of presenting a sum of £15,000 to the Liverpool University College, in commemoration of the Jubilee year.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5317 births and 3652 deaths were registered during the week ending Dec. 4th. The annual death-rate in these towns, which had been 19·1 and 20.1 per 1000 in the preceding two weeks, further rose last week to 21·0. During the first nine weeks of the current quarter the death-rate in these towns averaged 19·3 per 1000, and was 2·3 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 14·2 in Birkenhead, 14·3 in Brighton, 16·5 in Nottingham, and 17·0 in Derby. The rates in the other towns ranged upwards to 26·0 in Leeds, 26·6 in Manchester, 27·9 in Plymouth, and 32·1 in Oldham. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 411, 402, and 400 in the preceding three weeks, further declined last week to 379; they included 134 from measles, 70 from scarlet fever, 61 from whooping-cough, 46 from diarrhœa, 36 from "fever" (principally enteric), 32 from diphtheria, and not one from small-pox. The lowest death-rates last week from these zymotic diseases were registered in Nottingham, Bolton, and Derby; and the highest in Leeds, Wolverhampton, and Halifax. The greatest mortality from measles occurred in Bristol, Halifax, Leeds, and Wolverhampton; from scarlet fever, in Salford, Bradford, Manchester, and Plymouth; and from whooping-cough, in Oldham, Huddersfield, Halifax, and Sunderland. The 32 deaths from diphtheria in the twenty-eight towns included 12 in London, 8 in Liverpool, 5 in Birmingham, 2 in Manchester, and 2 in Oldham. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding four weeks from 293 to 413, further rose last week to 444, but were 35 below the corrected average. The causes of 99, or 2·7 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Newcastle-upon-Tyne, Bolton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Hull, Preston, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·4 per 1000 in each of the preceding two weeks, rose to 23·1 in the week ending Dec. 4th; this rate was 2·1 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 12·5 and 18·5 in Greenock and Leith, to 27·3 in Glasgow and 27·9 in Perth. The 570 deaths in the eight towns last week showed an increase of 42 upon the number in the previous week, and included 25 which were referred to scarlet fever, 19 to whooping-cough, 17 to diarrhœa, 9 to measles, 8 to diphtheria, 3 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 81 deaths resulted from these principal zymotic diseases, against 81, 77 and 64 in the preceding three weeks. These 81 deaths were equal to an annual rate of 3·3 per 1000, which exceeded by 1·1 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of scarlet fever, which had been 24 and 14 in the previous two weeks, rose last week to 25, of which 19 occurred in Glasgow, 3 in Dundee, and 2 in Edinburgh. The 19 deaths from whooping-cough showed an increase of 2 upon the number in the previous week, and included 16 in Glasgow and 3 in Edinburgh. The 17 deaths attributed to diarrhœa corresponded with the number in the previous week. The 9 fatal cases of measles exceeded the numbers in recent weeks, and included 7 in Glasgow. The 8 deaths from diphtheria also showed an increase; 3 were returned in Glasgow and 3 in Edinburgh. The 3 deaths referred to "fever," however, showed a marked decline, and included 2 in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 137 and 125 in the preceding two weeks, rose last week to 142, but were 33 below the number in the

corresponding week of last year. The causes of 78, or nearly 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 23·6, 24·5, and 25·3 per 1000 in the preceding three weeks, further rose to 28·1 in the week ending Dec. 4th. During the first nine weeks of the current quarter the death-rate in the city averaged 24·0; the mean rate during the same period was but 17·8 in London and 19·2 in Edinburgh. The 190 deaths in Dublin last week showed a further increase of 19 upon the numbers returned in recent weeks, and included 8 which were referred to scarlet fever, 7 to "fever," (typhus, enteric, or simple), 3 to diarrhœa, 2 to whooping-cough, 1 to measles, and not one either to small-pox or diphtheria. Thus 21 deaths resulted from these principal zymotic diseases, against 23, 20, and 22 in the previous three weeks; they were equal to an annual rate of 3·1 per 1000, the rates from the same diseases last week being but 1·7 in London and 2·5 in Edinburgh. The fatal cases of scarlet fever, which had been 15, 10, and 7 in the preceding three weeks, were 8 last week. The 7 deaths from "fever," corresponded with the number in the previous week, while the fatal cases both of diarrhœa and whooping-cough showed a decline. Five inquest cases and three deaths from violence were registered; and 69, or more than a third, of the deaths occurred in public institutions. The deaths both of infants and of elderly persons showed an increase upon the respective numbers in the previous week. The causes of 32, or nearly 17 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

THE MEMBER, THE FELLOW, AND THE FRANCHISE.

To the Editor of THE LANCET.

SIR,—In an editorial notice of Mr. Erichsen's pamphlet, "The Member, the Fellow, and the Franchise," in THE LANCET of Dec. 4th, many of the author's statements are characterised as "visionary." Were it not that Mr. Erichsen's reputation for propriety and honesty of purpose is above suspicion, a stronger epithet might have been employed without undue severity. Whatever may have been the motive of Mr. Erichsen's speech at the College of Surgeons on Nov. 4th, or whatever be his personal justification and apology, the part which he is now playing does seem different from that which had popularly been assigned to him. Be this as it may, the publication of the pamphlet cannot fail, in spite of itself, to influence beneficially the progress of the present agitation for effectual reform. It shows at once the hollowness of the arguments and the untenability of the position of those who oppose a readjustment of the relations between the Council and the rest of the body politic and corporate of the College. Whether designedly or not, the publication of Mr. Erichsen's pamphlet will almost coincide with the issue to the Fellows of the interrogations of the Council, as to whether Members of the College shall, under certain restrictions, be empowered to vote in the election of the Council and be eligible to sit in the Council itself or not. This conjunction gives the pamphlet a degree of importance which it would not otherwise have had, and warrants a scrutiny which could not under ordinary circumstances be justified. If, however, the matter be closely examined, it will be found that Mr. Erichsen scarcely makes a statement or draws an inference which cannot be directly controverted, or which does not at least require considerable modification.

In his exposition of the respective rights, rank, and status of Members and Fellows, and of the conduct, character, and constitution of the Council, Mr. Erichsen traverses a wide range of thought, interspersing his remarks with disquisitions on jurisprudence, politics, ethics, metaphysics, economics, pædagogics, biology, surgery, and antiquarian lore. Entertaining though all these things might otherwise have been, the only observations pertinent to the present issue are those which refer to the claims of Members to the franchise, to the prestige and the monopoly of the Fellows, and to the influence and action of the Council.

With a little trouble Mr. Erichsen's remarks may be arranged generally under three heads—namely, those relating (1) to Members, (2) to Fellows, and (3) to the Council. It is, however, predictive of the confusion of thought which is the prevailing characteristic of the pamphlet to find, at the outset, that what is entitled an "Appendix" appears as the *Preface*. This extraordinary disposition is doubtless intended to give the "Appendix" greater prominence; it would have been well if equal care had been taken to ensure greater accuracy.

In opposition to the claim of Members to take part in the election of the Council, Mr. Erichsen contends, first, that Members have never possessed the "right" to elect members of the Council (p. 7 *seq.*); second, that inasmuch as they have passed only a "minimum qualifying examination," they ought not, in accordance with the custom of kindred institutions to be entrusted with this privilege (pp. 4 and 6); and, third, that they are by training and pursuits unfit to take part in the direction of a great educational and scientific institution (*passim*). The Member of the College of Surgeons is, he says, a registered student who has passed a minimum qualifying examination in Anatomy, Physiology, and Surgery, and stands, therefore, on exactly the same level as a Licentiate of the College of Physicians (p. 4). And "the L.R.C.P. can never in his wildest dreams of professional ambition have looked forward to the possibility of his becoming one of the governing body of the College of Physicians", &c. Yet this "wildest dream" has possessed men whose name, fame, and memory are not altogether so contemptible as Mr. Erichsen's assumption would seem to imply. The Licentiates of the College of Physicians were regularly summoned to the *comitia majora*, up to the year 1765, when the practice was abruptly discontinued. In 1767 a number of Licentiates, amongst whom were William Hunter, John Fothergill, Alexander Russell, and other eminent men, associated with a view of taking legal proceedings against the College for the recovery of their right of incorporation. Eventually, in January, 1770, Dr. Archer and Dr. Fothergill did move the Court of King's Bench for writs of mandamus to compel the College to admit them. The case was argued in April, 1771, when Lord Mansfield and the other judges expressed the opinion that *Licentiates* could not set up their licence, accepted under a bye-law, as a foundation of a right to be admitted under the Charter. This ruling therefore disposed of the claim of Licentiates to be admitted to the College, and determined the radical and essential difference between a Licentiate and a Member. In this light Mr. Erichsen's forced and fanciful comparisons of the corporate status of a Member of the College of Surgeons and any Licentiate whatever turns out to be an unsubstantial figment. The only really apposite comparison which he draws is that between a Member of the College and a Graduate of the University of London who possesses only a lowest degree. Each occupies a precisely identical position in so far as he has passed only a "minimum examination." But here, according to Mr. Erichsen, the comparison ends. "There is not a single M.B. in the Senate," he says (p. 7), thereby implying, as indeed he did actually state in his speech at the College, that Bachelors of Medicine and others who had taken only a minimum degree are ineligible for a seat in the Senate, and on that account. Now it is true there is no M.B. in the Senate of the London University, and for an obvious reason; but the only legitimate interpretation which Mr. Erichsen's allusion will bear is not true. There are at the present moment no less than *four* members of the Senate who possess degrees of the lowest grade only.

In discussing the fitness of Members to take part in the direction of the educational and scientific departments of the College, Mr. Erichsen applies a test to which no reasonable person can object. "Who," he asks, "but men of science can control and direct efficiently a scientific department, and where are to be found the men of science connected with the College of Surgeons? Are they amongst its Fellows or in the ranks of its Members? The Fellowship of the Royal Society may be taken as indicative. ..... Now where, I would ask, are the Fellows of the Royal Society to be found—amongst the Fellows or amongst the Members of this College?" Mr. Erichsen puts the question fairly enough, but he leaves it unanswered,—except by insinuation. Once more he is in [illegible] latest published list of Fellows of

the Royal Society contains the names of at least thirty-one Members of the College—probably more,—and only of eight Fellows by examination. There are in addition fourteen Fellows of the College by election, and as they have, according to Mr. Erichsen's criterion, only passed the "minimum qualifying examination," they should be classed with Members; so that there are in the Royal Society forty-five Members of the College and only eight Fellows! Where, indeed, are the Fellows of the Society to be found? Where?

With a view of impressing the existing Members of the College with a due sense of the unreasonableness of their demand for electoral powers, Mr. Erichsen gravely remarks that originally the Council was self-elected, and its elections were controlled by the Court of Examiners, and that it was "in order to correct this obviously corrupt state of things" that the order of Fellows was instituted (p. 8). From that time forth all was well; finality was then attained. Those who wish to obtain the franchise may, he observes, do so by becoming Fellows (p. 8); indeed, it would appear that the franchise is the sole use and purpose of the Fellowship. "The Fellowship was instituted in order to create an electoral body" (p. 15). It may be so, but, on the other hand, Sir Benjamin Brodie, the acknowledged author of the order of the Fellows, has given a different explanation of the origin and intention of this institution. "The object of this institution," he says, "is to ensure the introduction into the profession of a certain number of young men who may be qualified to maintain its scientific character, and will be fully equal to its higher duties as hospital surgeons, teachers, and improvers of physiological, pathological, and surgical science afterwards. With this view, if they have not University degrees, they are required to undergo a preliminary examination in classics and mathematics; while their professional education having been continued for a longer period of time, they are expected to show that they have a more perfect acquaintance with those sciences which are the foundation of medical and surgical knowledge than can be expected of the great majority of those who are candidates for practice. If this system be properly and honestly carried out, I apprehend that the result will be that the Fellowship of the College of Surgeons will be the most honourable distinction that is offered to the junior members of the medical profession." Is this system being properly and honestly carried out by restricting the franchise to the Fellows in opposition to the wishes and aspirations of more than 16,000 of the members of the corporation, while the academic status is being persistently debased in the silly hope of allaying the disaffection of a few Members by the offer of a cheap but degraded Fellowship? The truth is, that the intellectual and professional prestige of the Fellowship is being seriously prejudiced by its forced association with an exclusive and obnoxious electoral privilege—a privilege, be it remembered, which is also an usurpation; for though it is true that the Members never did possess electoral rights, it is nevertheless a fact that by the Charter of 1843 they were deprived of their inherent rights of eligibility for election to the Council and to the office of president.

There is, however, one possible contingency which in Mr. Erichsen's opinion might justify a change in the constitution of the College; but this, he thinks, is happily absent. "The advocates of change do not," he says, "rest their case on the only ground that would be unassailable—namely, that the Council of the College has been negligent or indifferent to the conduct of its affairs, and that its interests—material, educational, and scientific—have consequently suffered in their hands" (p. 4). What these interests and duties are he elsewhere describes—namely "the controlling of medical education" (p. 3), "the conduct of examinations" (p. 9), and "the supervision of surgical education" (p. 11). Most persons who have not enjoyed an "official connexion with the College" are under the impression that the Legislature has committed the care and keeping of these interests to the General Medical Council, to whose opinions and decisions the influence of the Council of the College of Surgeons must always be subordinated. Indeed, it is no secret that the General Medical Council has, in the past, more than once had to take the Council of the College and its Court of Examiners seriously to task for scandalous defects and misconduct in examinations. But let it be for the moment allowed that the Council of the College does possess all the influence and importance which Mr. Erichsen claims for it. How has it discharged its duties and obligations to the profession and the State?

The College was established in the year 1800. In 1818 Sir C. Monk said in the House of Commons, "The usual examination before the College of Surgeons is conducted in a very loose and slovenly manner"; and on the same occasion Mr. Peel suggested that the fees required for the diplomas were alone looked to, and that the examinations were a mere formality. In the year 1826, at a large meeting presided over by Mr. (afterwards Sir William) Lawrence, a resolution was passed condemning the examination "as perfectly ridiculous as a test of qualification." This state of things continued almost unchanged for a further period of forty years. Mr. John Simon, writing in the year 1865, says of the late Joseph Henry Green, whose long connexion with the Council of the College of Surgeons began in the year 1835:—"I know it to have been against his judgment that the Council of the College of Surgeons, charged with the high trust of providing for the due qualification of persons who by that portal shall enter the medical profession, persisted in regarding its own ranks as the only source from which to appoint examiners for this important purpose—a view in which, alas, it still persists, though involving the absurdity and scandal that persons (superannuated hospital surgeons and the like) are thus the College's sole examiners in those daily growing sciences of physiology and pathology which the College affects to promote in the interests of the profession and the public."

In 1866-7 the Visitors appointed by the General Medical Council to inspect and report on the examinations of the College called attention to the imperfect character of the examination, and to the fact that the Council of the College granted its diploma to practise without requiring any examination in medicine. In consequence of this exposure examiners in medicine were appointed in 1868. In 1874 the Visitors again called attention to defects in the examination, and though some of the recommendations of the Visitors were adopted the most important of them were evaded. In 1881 a Royal Commission inquired into the Medical Acts. The Commissioners in their report called attention to the fact that "even the diploma of the Royal College of Surgeons of England does not imply a knowledge of midwifery." Alarmed at the possible influence which the publication of this "prominent defect" might have upon the course of threatening legislation, the Council had recourse to its old strategy of hurriedly adopting an innovation which could no longer with prudence or with safety be resisted. Examiners in midwifery for the diploma of Member were consequently not appointed till the eighty-first year of the College's existence, and then, as in the previous case of the examiners in medicine, only as the result of external pressure.

The foregoing accusations can be supported by unimpeachable evidence. I wish in conclusion to guard against a possible misinterpretation. I have not the least desire to incriminate individual members of the Council. They are gentlemen of high professional reputation, and fully deserve Mr. Erichsen's eulogium on the goodness of their intentions and the sincerity of their devotion. But this only emphasises the necessity for a complete and radical reform in the constitution of the College. How vicious must that constitution be that can deprave so excellent a Council!

I am, Sir, yours &c.,

December, 1886. HISTORICUS.

THE LATE DR. NORMAN CHEVERS.

To the Editor of THE LANCET.

SIR,—I shall feel obliged if you will afford me space to meet, however imperfectly, the claims of a long friendship, and of my profession, by expressing in a few words my deep sense of the loss we have had in the sudden death of Dr Norman Chevers. His death was not strictly premature, for he was sixty-eight years of age, but his useful pen was still active. Dr. Chevers was a student of the then united hospitals of Guy's and St. Thomas's. He passed the main part of his professional life in India, and wherever known, all who intimately knew him recognised that he possessed rare mental endowments, and these were combined with the highest and most delicate sense of honour. His writings are extensive, including "Medical Jurisprudence for India," for which our College of [illegible] awarded him the Swiney prize; a volume on "[illegible] of India," just published; and numerous [illegible] Guy's Hospital Reports, to the "Indian [illegible] British Medical Journal.

What he wrote was not only of great value to the literature of medicine, but its value was enhanced by the fair and truthful spirit which everywhere breathed in his writings. I believe that Sir Joseph Fayrer, who was one of Dr. Chevers valued colleagues in India for many years, will give the profession an ampler memoir.

I am, Sir, your obedient servant,

Brook-street, W., Dec. 8th, 1886. WILLIAM W. GULL.

THE APOTHECARIES AND THE CONJOINT SCHEME.

To the Editor of THE LANCET.

SIR,—Much has been said as to the necessity of admitting the Apothecaries' Society to the Conjoint Scheme, and very much can be said against it. Let us, if possible, examine the position critically and impartially, and, putting sentiment aside, endeavour to ascertain what is the best course for the profession to pursue in this matter. It is argued that, if the apothecaries be not allowed to amalgamate with the Colleges, a new and competing class of practitioners will be created. Now, this argument is quite incorrect, and will not bear a moment's consideration. The Society, by taking powers to itself to qualify in surgery as well as in medicine and midwifery, will not induce more students to take its licence than already take that estimable qualification; such gentlemen, though legally qualified to practise surgery, will, as licentiates of a Society of Apothecaries, remain, as heretofore, apothecaries; they will be no more entitled to dub themselves surgeons than they are at present entitled to style themselves physicians.

Hitherto, the Society's licentiates, if desirous of qualifying in surgery, have been compelled either to go to the London College, and pay another and larger fee, or to Edinburgh; and if the authorities at Lincoln's-inn-fields do not object to the loss of these fees, why should the profession object? Again, the class of students who now go up for the much more stringent examinations at the College of Physicians will not, in the future any more than at present, go to the Apothecaries' Society because its licence happens to be also a qualification in surgery. Let us grant for a moment that the apothecaries are admitted to the Conjoint Scheme, what is the result? The examination fee, which is now, supposing there be no rejection at any stage, thirty-five guineas, will be raised to forty-one guineas, and every student who wishes to become an apothecary will have to pay this large sum as well as pass the conjoint examinations—that is to say, every apothecary must also be a physician, and every physician an apothecary. How the Edinburgh Colleges would rejoice at such an arrangement, and what shoals of Scotch licentiates we should soon have practising in England! As to the supposed power of the Apothecaries' Society to suppress illegal practice, the less said about it the better. It is an ancient and rusty weapon, and, judging from recent events, more likely to be used against ourselves than in the suppression of the salve-mongers and practising druggists. Having now, I think, shown that the arguments in favour of amalgamation are worthless, I would point out that the profession has solid work before it in the proposed reform at the College of Surgeons, and should not allow its energies to be diverted from that great object in order to attack the Colleges conjointly, and probably without even a chance of success.—I am, Sir, your obedient servant,

Dec. 6th, 1886. A LATE HOUSE-PHYSICIAN.

THE MEETING OF THE METROPOLITAN COUNTIES BRANCH.

To the Editor of THE LANCET.

SIR,—The meeting at Jermyn-street on the 3rd inst. cannot be regarded as a very great success from any point of view. There is no doubt that it was disappointing, both to the promoters and to those who went there prepared to hear the subject freely debated. For, in spite of unprecedented effort on the part of those who are best in a position to give effect to their views, only about seventy members out of a roll approaching 1000 attended a meeting upon objects which have been proclaimed to be of vital importance to every member of the profession. Even when it came to actual voting, so languid was the interest that only thirty-nine could be found to support the resolutions which it was hoped would strike terror into the hearts of the College authorities. It may well be that the evils of the exclusion of the Apothecaries' Society from participation in the Conjoint Board have been overdrawn, and that the vast majority of practitioners regard without dismay a possible renewal of existence for a Society which, it must be admitted, has done good work in the past, and will doubtless continue to do good and useful work in the future. But the speaking was all on one side, and therefore it is impossible to judge what are the opinions of those who maintain this proposition. The temper of the voting majority was, moreover, not wholly conducive to quiet and reasonable debate, as was evinced by the reception of a very simple suggestion that the rights of the Members of the College of Surgeons to the franchise should be distinguished from the wholly novel claim put forward on behalf of the Licentiates of the sister College. It would have been more consonant with dignity had the latter plea been urged on its own merits, and not allowed to depend for its support upon a movement which has far greater claims to be entertained. Another interesting episode of this abortive meeting was the dilemma in which its promoters found themselves, either of passing resolutions which could not be legally enforced or of empowering the Council of the Branch to take action upon them. The latter course was forced upon them, and had to be yielded to unless it was wished to show that the Council did not enjoy the confidence of the Branch. So far as can be gathered from the whole business, it would be wise for those who are urging these questions to take measures for ascertaining the *real* feeling of all members of the profession upon them; for if they pursue their present policy and abide by the result of meetings such as this they will do more to divide the profession than the British Medical Association has ever done to unite it. It was not for this that the Association was founded.

I am, Sir, yours faithfully,

Dec. 6th, 1886. A MEMBER OF THE ASSOCIATION.

THE PUPILS IN CHEYNE-STOKES' RESPIRATION.

To the Editor of THE LANCET.

SIR,—The phenomena so well described by Dr. Robertson in THE LANCET of the 27th inst. are of much interest, but his observations are not altogether novel. I saw and took notes of a case about six years ago in which the same phenomena were presented in a typical form, but found on consulting the literature of the subject that similar cases had already been described by Ziemssen, Bernheim, and Biot. The latter ("Étude Clinique et Expérimentale sur la Respiration de Cheyne-Stokes," Paris, 1878) relates several cases in which the rhythmic contraction and dilatation of the pupils were observed, the latter always coinciding with the period of respiration, the commencement of which was also frequently attended by convulsive movements of the limbs. The rapidity with which dilatation took place seemed to vary in different cases; in my own case it was neither instantaneous nor continuous, but passed through a series of gradations, and the effect of light at any stage was inappreciable. As in other cases, the pupillary phenomena disappeared some hours before death.

Biot refers the phenomena, apparently with justice, to changes in the arterial tension, the pupils contracting as the pressure falls, and *vice versâ*. He instances the fact that when a patient is attacked with dyspnœa, especially if the subject of cardiac disease, and makes violent efforts to force air into the chest, the pupils enormously dilate. He further refers to the experiments of Claude Bernard, which showed that section of the sympathetic in the neck leading to vaso-motor paralysis and diminution of arterial tension was always accompanied with contraction of the pupils. Indeed, the contraction of the pupils and flaccidity of the muscles during the period of apnœa are nearly on a par with all the other vital phenomena at the same time. The patient is for the moment, so to speak, comparatively dead, every function and sense being in abeyance.—I am, Sir, yours &c.,

Partick, Glasgow, Nov. 29th, 1886. R. KIRK, M.D.

To the Editor of THE LANCET.

SIR,—In your issue of this day's date Dr. Alex. Robertson directs the attention of other observers to the rhythmic contraction and dilatation of the pupils noticed by him in some

cases of Cheyne-Stokes' respiration, the pupils being dilated when the breathing was full and laboured, but progressively contracting during the descent and cessation of the respiration. This point has already engaged the attention of some observers; and in an article on Cheyne-Stokes' respiration, published in the *British Medical Journal* so long ago as August 31st, 1878, I mentioned that "Ziemssen and Biot noticed contraction of the pupils during the period of apnœa, relaxing during the period of respiration" (*loc. cit.* p. 310). That the rhythmical contractions also affected the muscles of the limbs gives additional interest to the first of the two cases now reported in THE LANCET.

I am, Sir, yours truly,
W. JULIUS MICKLE, M.D.

Grove Hall, London, Nov. 27th, 1886.

THE HYDROBROMATE OF HYOSCINE IN A CASE OF ATROPINE IRRITATION.

To the Editor of THE LANCET.

SIR,—In the last number of THE LANCET, Mr. Tweedy, in an article entitled "On the Mydriatic Properties of Hydrobromate of Hyoscine," mentioned some observations I had made on the action of this alkaloid. Since that was written I have used it in a case of atropine irritation, in which, after three applications of a two grains to the ounce solution of atropine considerable swelling and redness of the eyelids and of the side of the face had followed. The hyoscine was used three times a day for six days without the least irritation; the case was one of old iritis, in which iridectomy had been performed, and inflammatory symptoms were again commencing. It was very desirable that a mydriatic should be used. Under the influence of hyoscine the threatened attack entirely passed away. Should this happy result be confirmed by other cases, and should it also be found by extended experience not to produce delirium, as is often the case with duboisin, it will prove a very valuable drug.

I am, Sir, yours truly,
E. TREACHER COLLINS.

Royal London Ophthalmic Hospital, Moorfields, E.C., Dec., 1886.

To the Editor of THE LANCET.

SIR,—In the *Ophthalmic Review* for 1882 (p. 343) are some remarks of mine on this drug. My own experience was then confirmatory of that of Emmest of Berne,[1] and will be found to agree in the main with the interesting observations of Mr. Tweedy, in THE LANCET of Dec. 4th. Emmest stated that a drop of one-tenth per cent. of hyoscine solution was more rapid and more manifest on the pupillary sphincter and the accommodation than a drop of atropine solution of one-half per cent. I was able to bear out this statement, and was convinced that for rapid pupil dilatation and for paralysing the accommodation it was a valuable drug, and that its effects were as lasting as atropine, or more so. I used it both before and after writing the article in many cases of iritis, and found it more powerful than atropine for breaking down adhesions. Mr. Tweedy states that he has not yet met with any instance of its producing toxic effects. My experience was the reverse, and to mention the following facts is my chief object in writing this letter. Subsequently to publishing the article before referred to, at my request Messrs. Savory and Moore made with their well-known care gelatine discs for me of the hydrobromide, which they considered the most suitable salt for the purpose. The strength was, I believe, the same as the watery solution I then employed—viz., 1 in 1000. In two cases only were the discs used. One was a young lady with astigmatism, and it was employed for paralysing the accommodation prior to testing the refraction; the other was a middle-aged lady with iritic adhesions. I believe only one disc was used in each case, but in both unpleasant symptoms, giddiness, confusion of ideas, &c., and in the young lady especially, faintness supervened, very similar to what I had observed with duboisin, but perhaps less severe. The symptoms continued a good long time. Before this I had employed the watery solution in many cases, some for refraction, but mostly in place of atropine for iritis, and I do not now recall any ill effects. The salt used was the iodide. The conclusion I arrived at was that in certain cases of iritis it was undoubtedly useful, but that it was more dangerous than atropine, and therefore it came to be less used by me. I have used and do use largely ophthalmic discs, and believe in their convenience, and I wish to guard against any impression prejudicial to their employment generally.

I am, Sir, yours truly,
SIMEON SNELL,
Ophthalmic Surgeon to the Sheffield General Infirmary.

December, 1886.

THE PREVALENCE OF SHINGLES.

To the Editor of THE LANCET.

SIR,—There appears to be more than the usual amount of this troublesome, and frequently painful, malady just now. Dr. Aitken remarked, in an early edition of his Practice of Medicine, that "a special mystery envelops its origin"; and in the twenty years which have elapsed since this was written little has been done to clear up this mystery. No satisfactory explanation has been given why in one case the neuralgic pain, which sometimes is very intense, should precede the eruption, in another accompany it, and in a third succeed it. Fifty years ago Dr. Anthony Todd Thomson wrote that it might occur several times in the same individual, whilst more modern views favour the belief that one attack is prophylactic of another. That the malady is often intimately associated with some nerve trouble, there appears now no reason to doubt. But Sir Erasmus Wilson, in his last contribution on the subject, believed the *predisposing* cause to be the gouty or rheumatic diathesis, and that a chill acted only as a secondary or *exciting* cause. The present prevalence of the malady affords opportunities for further clinical observations. The relation of shingles and other forms of herpes to pneumonia is full of interest. Why should pneumonia be so frequently accompanied by herpes labialis, and so rarely by herpes zoster or shingles? And yet when shingles prevails largely pneumonia is apt to be prevalent also, but not in the same persons. It may be a consolation to some who are suffering intense pain from shingles to think that they have possibly just escaped an attack of the graver malady, pneumonia. Not that by this it is intended to imply that an attack of shingles is a trifle, for it frequently is accompanied by great prostration of the nervous system, causing irregularity of the heart's action, needing prolonged care to ensure entire restoration to health. Three typical cases have recently come under my care: in one the rash occupied one side of the neck—the right side; in another it followed the line of the external cutaneous nerve of the right thigh; and in the third it spread over the left half of the chest. In each of these cases the pain was very severe, and in two of them the heart's action was embarrassed, so as to produce an intermittent pulse and much præcordial distress. In the case affecting the neck this symptom was absent. In THE LANCET, vol. i. 1882, some interesting cases of trophic herpes are recorded. In calling to memory some fifty cases of fracture of the ribs, in no instance did any herpetic eruption follow the injury which the nerves must receive from this accident, though it is believed that there is some connexion between herpes zoster and nerve injury.

I am, Sir, yours obediently,
A GENERAL PRACTITIONER.

December, 1886.

MERLATTI'S PULSE.

To the Editor of THE LANCET.

SIR,—There is a mistake in my letter of Dec. 1st, which appears in THE LANCET of Dec. 4th. The last paragraph on page 1104 should read, "The *sixth* tracing taken on the afternoon of the thirty-*fourth* day caused me some surprise, as it shows a temporary restoration of the blood." The *fifth* tracing shows the progressive diminution of volume, and was taken at the same hour as all the others (6 P.M.), except the fourth, which is that of the thirty-third *morning*, when the pulse was said by the medical men to be filiform, a condition well seen on the tracing. Since then the pulse has varied between 60 and 120 to the minute, being sometimes filiform, at others bounding. I must also ask your readers to insert the words "on the evening of the thirty-fourth day" after "if an enumeration had again been made," on page 1105.—I am, Sir, yours faithfully,

THE PARIS CORRESPONDENT OF THE LANCET.

Paris, Dec. 7th, 1886.

"THE M.Ch. DEGREE."

To the Editor of THE LANCET.

SIR,—I was very pleased to see that "M.Ch." had started the question of the injustice under which holders of the Master of Surgery degree have been suffering for a long time past in regard to hospital honorary appointments. I sincerely hope that hospital authorities will see their way to altering a rule which has now become effete, inasmuch as there are many more eligible men than formerly holding the C.M. degree, who are shut out from ever holding appointments as hospital honorary surgeons. Could not you, Sir, do something to help these outcasts by bringing the subject prominently before the Medical Council.

I am, Sir, yours truly,

December, 1886. C.M.

THE UNIVERSITIES OF GREAT BRITAIN AND IRELAND AND MEDICAL DEGREES.

(*From a Correspondent.*)

IN THE LANCET of the 27th ult., it is pointed out as a serious objection to the granting of a Medical degree by the Royal College of Physicians of London and the Royal College of Surgeons of England, acting conjointly, "that a degree can only be properly given by a university." Admitting the force of the objection, it is of the utmost importance to the just appreciation of the question to point out the present relations of the universities to medical students and the conferring of medical degrees. They may be easily divided into classes. Thus:—

1. The University of London and the Royal University of Ireland merely require attendance on certain lectures and hospital practice at named institutions, but do not insist on residence at any particular school or place, and rely on an examination test principally. 2. The Universities of Oxford and Dublin (Trinity College) insist on a candidate being previously a B.A. of one of these universities, as well as on residence for a certain number of terms; but at Cambridge the B.A. is not imperative, and non-collegiate students are permitted, and are on the increase. At Oxford and Cambridge a B.A. degree can now be taken in Natural Science, and such scientific education exempts a medical student from some portions of his medical curriculum. The clinical study for Oxford and Cambridge degrees is usually obtained in London. 3. The Scotch universities require only the passing of a matriculation examination, and then the student passes on to a strictly medical course (two years of his time being spent at the special university at which he presents himself for his degree), and he may attend many lectures at an extra-mural school. There is no supervision over the lodgings in which students live, and residence in the sense of Cambridge, Oxford, and Dublin is unknown. There are no colleges, and he only learns who are the professors in the other faculties when his degree-testamur is signed. The Victoria University is framed on similar lines to the Scotch universities, but consists of two colleges—Owens College at Manchester and University College at Liverpool. These are not residential. 4. The University of Durham: A knowledge of Greek, which may be passed at any university, is the only additional requisite to any qualifying preliminary examination of the medical student. A year's attendance is imperative, and this is passed in clinical study at the infirmary at Newcastle-on-Tyne. The student may reside anywhere, so long as he attends some lectures during the year.

In discussing the question of the necessity of residence at a university, and the culture that is obtained therefrom, it is important that it should be fully known to the profession how dissimilar this condittion and its derived advantages may be at the various universities.

LIFE-GOVERNORSHIPS TO HOSPITALS.—On the 7th inst. the anniversary dinner of the East London Association for promoting life-governorships to hospitals was held at the Three Nuns Hotel, Aldgate, under the chairmanship of Lieut.-Colonel and Sheriff Kirby. The Society was formed in 1873, and has been the means of increasing the funds of the various London hospitals to the extent of £4000.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

A WEEK OF DISASTERS IN THE NORTH.

LAST week was one of disasters. The explosion at the Elemore Colliery, by which twenty-five miners lost their lives on Thursday last, was succeeded on Friday by an explosion and fire on the Gateshead side of the Tyne, and just above Newcastle, causing the deaths of four persons from burns and contusions of a dreadful nature. In addition to these disasters, we have been kept in an almost constant state of alarm by other fires, no less than seven or eight taking place in Newcastle and Gateshead within the week, or as many as occur in an ordinary way in twelve months. I happened to be near the Teams fire which took place on the Gateshead side of the river, nearly opposite Sir William Armstrong's works. We, on the Newcastle side, heard a loud report as if from a very heavy piece of ordnance, then a tongue of flame shot into the air to a great height. This was followed by a dense column of black smoke, which soon spread over the west-end of the city, and, it being noonday, it presented a very peculiar appearance. The scene of the fire was a factory where tar products were manufactured by various processes, including distillation; the works were burnt to the ground. The dangerous nature of the manufacture will be seen from the statement that this is the third fire which has occurred at the place within the last three or four years. The manager was blown fully sixty yards from the works, and died from his injuries, as well as three of the workmen, in the infirmary. The dreadful nature of the fire will be seen from the evidence of one of the witnesses at the inquest, who said "he was at his own house, about 600 yards from the tar works, when he heard a report, and thought it was a cannon at Sir William Armstrong's works. He ran as fast as he could to the works. He saw the deceased running out all on fire. Witness took off his shirt and covered him; he was burnt all over, and was removed to the infirmary, where he died."

DURHAM UNIVERSITY.

The *Durham University Journal* is apparently taking up the cudgels on behalf of the ladies, and says:—"We regret to announce that at a hastily-summoned meeting on Monday the Senate decided by a single vote to reject the offer to convert Hatfield Lodge into a College for Women. The history of the opposition to this scheme we forbear to characterise out of respect for the Senate and regard for the University. The theory of the Senate is that its proceedings are private, and it is obviously desirable that the practice should be made as far as possible to correspond with the theory. Doubtless there are occasions on which the proceedings of the Senate might be published, if it thought fit, with advantage to the University. But this is not one of them."

SOUTH SHIELDS.

In South Shields an epidemic of scarlet fever continues to prevail. Fifteen deaths occurred during the four weeks ending Nov. 27th from this cause. Whooping-cough was also prevalent in a very fatal form during the same period. The medical officer, Dr. Monro, in reporting on these matters, pointed out that the town would be liable to periodical epidemics of scarlet fever, unless the authorities had more control over cases where isolation cannot be, or from carelessness is not, resorted to. A local paper says:—"The Council passed over the question without notice however. A corporate body desirous of making their borough a summer resort for visitors should certainly give the closest attention to everything affecting the public health."

THE DURHAM COUNTY HOSPITAL.

The opening of the new Eden wing of this hospital took place under very favourable auspices. Its erection is due to the munificent bequest of the late Mr. W. Eden of Beamish, co. Durham, and Eaton-place, London, a wealthy coalowner and landed proprietor. He was styled in the north "The Master of Beamish." One of the local papers points out that the generous bequest of the benefactor, owing to the action of the committee, has increased the size and responsibilities of the hospital without adding to its income, "for if they had spent £2000 on the ward, they might have

£10,000 to invest for its support." But at the same time its efficiency has been increased, and this should not be overlooked in the matter.

Newcastle-on-Tyne, Dec. 8th.

EDINBURGH.

(From our own Correspondent.)

THE CITY FEVER HOSPITAL.

THE "Public Health" Committee of the Edinburgh Town Council have justified their claims to such an appellation by a recommendation in favour of clinical instruction in fevers made to the municipal authorities. It is probable that the recommendation will be adopted, and the wards of the hospital thrown open to such students as wish to attend. Suitable arrangements for their instruction will be made under the direction of Dr. Jamieson, the visiting physician, and thus this very important branch of medical training will be placed within the reach of our medical students. It has been decided to recommend that no fee be charged in the first place, as the session is already advanced, but that the proposed course of instruction should be held tentatively, and according to its results as regards the numbers attending, and, as regards its effects on patients and students, will be either abandoned or established on a permanent basis for the future. A very important problem, fraught with good or evil to the Edinburgh School, is thus to be worked out. That clinical teaching, the thorough discussion of their condition and treatment, can only be beneficial to the patients, goes without saying; and a no less distinct benefit must accrue from the students' increased practical experience. But the effects produced upon the physique of those attending the course will be awaited with some anxiety. It is to be hoped that some age qualification will be demanded of these, in addition to the understanding that they are not attending other hospitals or lectures at the same time. Unless some stringent restrictions of this nature are imposed, the effects upon the medical section of the population, if not upon the community at large, may be very serious. These dangers are likely to be minimised, however, by the fact that in no curriculum is attendance upon fever cases a compulsory part of undergraduate training, and our students have now such a considerable load of compulsory instruction to stagger under, that it is not likely that many will find time to take part in the Fever Cliniques, specially if restrictions of the sort hinted at be enforced. If a special period of his career, when he is not otherwise overworked and susceptible to infection, be set aside by the student for the study of this subject, he will be able to minimise the attendant risk, and will commence his professional career as master of this important subject, not as a tyro in the study of its practical details.

ROYAL SOCIETY OF EDINBURGH.

The opening meeting of the 104th session of this Society took place on Monday, when Dr. John Murray, director of the work of the "Challenger" Commission, delivered the inaugural address. The state of the Society was favourably reviewed, and the large amount of research contained in its transactions and proceedings commented on as matter for congratulation. Dr. Murray then proceeded to detail some of the special work in physical science carried out under the auspices of the Society; the accounts of the marine stations on the east and west coasts, and of the Meteorological Observatory on Ben Nevis were replete with interesting facts, and show that, notwithstanding the neglect of Government in the matter of granting subsidies, scientific work of an advanced and most valuable type is actively carried on in Scotland.

THE UNION FANCY FAIR.

The five-days' bazaar last week realised a sum of over £10,000 for building a students' union for the University. A sum of £4000 was already subscribed, so that after deducting expenses about £13,000 will be available for building purposes.

ROYAL HOSPITAL FOR SICK CHILDREN.

Owing to Dr. Hodsdon's appointment upon the staff of the Royal Infirmary, a vacancy has occurred on that of the Sick Children's Hospital, and the managers will appoint an assistant physician two weeks hence. Several candidates for the appointment are in the field, amongst whom are Drs. Philip, Noël-Paton, W. Hunter, Dunlop, and John Thomson.

Edinburgh, Dec. 7th.

IRELAND.

(From our own Correspondent.)

THE EPIDEMIC OF ENTERIC FEVER IN CORK.

AT a meeting of the Public Health Committee of the Corporation of Cork held last week, an important communication was received from Dr. Donovan, medical officer of health, in reference to the present outbreak of enteric fever which prevails there. From his report it appears that the number of cases of enteric fever which occurred during the past three months amounted to about 150. The average number of cases in Cork for the past twenty years would be about eighty annually. Dr. Donovan is of opinion that although the water-supply may not be all that could be desired, yet it is perfectly innocent of the present outbreak. He comes to this conclusion for the following reasons:—1. The analysis of the water, taken at the most unfavourable times—namely, when floods set in and when the water was most charged with impurities,—always showed it to be safe to drink. 2. If it was owing to the water-supply, instead of having 180 cases of enteric fever, there probably would be some thousands of cases. 3. The absence of enteric fever, nay, even of cases of diarrhœa, from the workhouses, gaols, industrial schools, &c., institutions wholly dependent on the public water-supply, clearly indicates that the disease must be traced to some other source. 4. The character of the disease and its mode of attack, its slow incubation, and the absence of certain symptoms, point more to the entrance of poison into the system by means of impure air than to its absorption from contaminated water, which would give rise to speedier and better developed symptoms of the disease. Dr. Donovan, who possesses special facilities for forming an opinion, believes that the present epidemic is owing to the unclean condition of the city generally, streets, backyards, and premises; also to the badly-constructed sewers, which are simply stagnant cesspits, and to the want of ventilation and proper flushing of the sewers. The recent opening up and clearing out of old choked drains he regards as an additional factor. The following are his recommendations:—The regular and systematic removal of night soil and other refuse at the public cost—that is, the domestic scavenging of the entire city, with the reconstruction of depôts, and the ventilation and systematic flushing of the sewers in dry weather. The entire question of the drainage of the city will have to be considered in the near future; but in the meantime, the carrying out of the above suggestions will materially improve the health of the city.

ACADEMY OF MEDICINE IN IRELAND.

At a meeting of the Academy last week, Mr. E. H. Bennett exhibited a cast and specimens of a rather rare accident—viz., simultaneous fractures of both clavicles. There are only about eighteen examples known, and in eight cases only did union take place. He also showed specimens of fractures of the costal cartilages in a girl aged six, a most unusual age; the second, third, and fourth being broken on the left side; and the cartilage of the first rib being separated from the bone on the other side.

MEMORIAL TO THE LATE DR. SCOTT, OF LURGAN.

In Shankill Cemetery, Lurgan, there has recently been placed a monument over the remains of the late Dr. J. M. Scott, who died about a year since, aged thirty-five years. It consists of a pedestal of polished grey granite, 12ft. high, which bears the following inscription:—"This monument is erected by the friends of J. M. Johnston Scott, M.D., F.R.M., and C.S.L., in Lurgan and neighbourhood, who from an intimate knowledge of his worth place it here as a sincere tribute to his memory, his professional talents, and his exemplary benevolence as a physician. Died Nov. 30th, 1885, aged thirty-five years."

The opening meeting of the Carmichael College Medical Science Association took place last week, when the president, Dr. A. H. Corley, gave an address on Clinical Teaching and Clinical Study.

Surgeon Falvey, Army Medical Staff, has been admitted a Fellow of the Royal College of Surgeons in Ireland.

Dublin, Dec. 7th.

PARIS.

(From our own Correspondent.)

DENTAL ANÆSTHESIA; COCAINE.

M. GEORGES VIAN claims to have solved the problem of local anæsthesia in dentistry. After numerous trials of solutions of different strengths he has found that the soft parts about the maxillæ may be rendered completely insensible by the use of cocaine, associated with a 2 per cent. solution of carbolic acid. Five minutes before operating M. Vian dissolves five centigrammes (one grain) of hydrochlorate of cocaine in fifty centigrammes (ten drops) of the solution, and injects it into the gums, half way between the neck and the extremity of the root of the tooth. Half of the solution is injected on the palatine and the remainder on the labial side, pressure being made by the finger, when the needle is withdrawn, to prevent the exit of the fluid. Anæsthesia is perfect in three minutes. The quantity of cocaine advised by M. Vian seems somewhat large, but it is said to have been so used in eighty-seven cases without causing any unpleasant symptoms. *A propos* of cocaine, the *Semaine Médicale* gives some particulars of the fatal accident which led to the suicide of Professor Kolomnine. The Professor had decided to perform an operation for the removal of tubercle from the rectum of a female patient, and inquired of his colleague, M. Louschinsky, what dose of cocaine he might administer. The answer was that the maximum was two grains. Upon consulting special treatises, however, M. Kolomnine found that thirty cases of anæsthesia were recorded in which the quantity given had varied between six and ninety-six grains. In a similar operation to that he proposed to perform, a French surgeon had given forty-eight grains. In consequence of these references it was decided to employ twenty-four grains, which were introduced into the rectum by instalments. About half an hour after the operation the first symptoms of poisoning appeared, and notwithstanding the administration of nitrite of amyl, hypodermic injections of ether, oxygen and artificial respiration, &c., the patient succumbed. Hypodermic injections of morphia do not seem to have been tried, and I do not know whether they have been recommended in cases absolutely similar to this. I may mention, however, that I have seen symptoms of cocaine poisoning in subjects of morphia habit removed instantly by a hypodermic injection of morphia, and in one case five grains of cocaine had been taken hypodermically within ten minutes, and I have frequently seen the same antagonistic effect produced by a small quantity of cocaine in an overdose of morphia. It is also regrettable that strychnia was not tried in this case, for the experiments of Dr. Bignon having shown that cocaine is its physiological antidote, it is quite possible that the antagonism may be reciprocal. Dogs poisoned by strychnia to the extent of one milligramme (a fiftieth of a grain) per pound can always be saved by keeping up cocaine intoxication until the elimination of the strychnia.

SUGGESTION.

The *Comptes Rendus* of the Société de Biologie contain a preliminary note by MM. Fontan and Legard, on the results obtained by them by Suggestion. The cases related form part of a series of nearly a hundred, seen in hospital and private practice. The induction of hypnotism was always obtained as simply as possible, most often by occlusion of the eyes; and only failed to occur in three per cent. of the subjects. In the induced sleep therapeutic suggestions were made, and were certain in their effects. It must be observed that the cases described by MM. Fontan and Legard were not those of functional disturbances of the nervous system, such as are cured by any remedy in fashion, and in which the patient has faith; but to quote the words of the author, they were "circulatory and secretory disorders depending upon anatomical lesions." The articular stiffness which remains for weeks after traumatic arthritis, the impotence of the lower limbs, and the tendency to syncope following upon cerebral concussion disappear after one *séance* of suggestion. The painful reflexes set up by gonorrhœal prostatitis and pelvimetritis are as easily dissipated. Dyspepsia, with vomiting and obstinate constipation, can, they state, be cured instantly. One of the patients suffering from acute urethritis and prostatitis, with tenesmus and painful irradiations, was relieved of all pain, including that of micturition, in three sittings, and the cure of the urethritis was greatly accelerated by suggestion. The first suggestion was that there was to be no burning pain during micturition, nor in the thighs, perineum, or loins, and the patient was forbidden to urinate every ten minutes. It was no doubt too much to expect all at once, for after an improvement which lasted two hours the symptoms resumed their previous severity. The second suggestion, however, removed all pain definitively, and brought down the swelling of the prostate. A week later nothing remained but a urethral discharge, and the prescription by suggestion was as follows. "*There is to be no further discharge. The cure is to be absolute.*" And the next day it was so. There is a simplicity about this treatment by suggestion that ought to bring it into favour, although it may not meet with the approbation of manufacturers of sovereign injections and capsules. But perhaps we may not all be what Paracelsus termed "predestined to effect cures" of this kind—"Suggestio curat, sed quod ab omni factus medico vanum est." It would be interesting if those who are gifted with this power would re-examine the old alchemists' cures by transplantation, and those effected by Digby's weapon-salve.

Paris, Dec. 8th.

ROYAL COLLEGE OF SURGEONS.

AT the ordinary meeting of the Council held on Thursday, Dec. 9th, the Minutes of the last meeting were confirmed.

The following recommendations from the Committee of Management were approved, adopted, and entered in the Minutes:—

1. That Mr. T. Cooke's School of Instruction in Anatomy and Physiology in Brunswick-square be recognised as a "place of study" for candidates rejected at the Second Examination of the Examining Board in England, subject to an annual renewal of such recognition on application from Mr. Cooke. 2. That the Committee be empowered to determine questions relating to exceptions to the conditions of admission to the several examinations of the Examining Board in England. 3. That in the final part of Paragraph 18, Section II., of the Regulations of the Examining Board in England, relating to the interval of two years required to be spent in professional study between the date of passing the second examination and admission to the third or final examination, the words "two winter and two summer sessions" be substituted for "two years."

A report of the Committee, in which the practicability and advisability of adding a wing to the Museum of the College was affirmed, and in which it was recommended that the Council should confer greater powers on the Committee to enable them to consider and report on the question of extending generally the College premises, including the museum and library, the addition of workrooms, &c., was approved, adopted, and entered on the Minutes.

It was agreed to issue a circular to the Fellows in accordance with a resolution proposed at the last meeting of the Council, with respect to (1) Members being allowed to vote for Fellows as members of Council; (2) the admission of Members of the College to seats on the Council.

Mrs. Frank Buckland presented a chair, made by her husband, out of the bedstead of John Hunter.

It was decided that the regulations relating to the rejected candidates being required to produce certificates of additional attendance after rejection are to apply to the Primary Examination of the College when taken alone, as well as to the second Conjoint Examination.

A vote of thanks was given to Mr. Power, the Bradshawe lecturer, and he was requested to publish the lecture.

The consideration of a motion brought forward by Sir Spencer Wells, to the following effect, was deferred: "That although the Council is not inclined to agree with the first motion passed at the meeting of Fellows and Members, still it is willing to appoint a committee to confer on the subject."

THE BURIAL-PLACE OF WILLIAM HARVEY.—The tower of Hempstead Church, Essex, which fell down in 1882, demolishing the western portion of the nave and aisles, is about to be rebuilt, and the church generally restored, under the superintendance of the architect, Mr. Samuel Knight.

THE SERVICES.

Surgeon-General Sir A. Home, V.C., Principal Medical Officer of the Southern District, on the 6th inst. retired from the service, and was succeeded by Surgeon-General H. V. Reade, V.C. Sir A. Home, who has been in hospital for the last six weeks suffering from bronchitis, retires on reaching the age of sixty.

WAR OFFICE.—Army Medical Staff: Surgeon-Major Duke Parke is granted retired pay, with the honorary rank of Brigade Surgeon.

INDIA OFFICE.—The Queen has approved of the retirement from the service of the undermentioned officers:—Deputy-Surgeon General Henry Walter Bellew, C.S.I., of the Bengal Medical Establishment; Deputy Surgeon-General Henry Cook, M.D., of the Bombay Medical Establishment; Brigade Surgeon Robert Sander Bateson, of the Bengal Medical Establishment; and Brigade Surgeon Charles Thick Eves, of the Madras Medical Establishment. The undermentioned officer has been granted a step of honorary rank on retirement:—Brigade Surgeon Charles Thick Eves, of the Madras Establishment, to be Deputy Surgeon-General.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following were elected Examiners for the ensuing year:—

Examining Board in England: First Examination. Elementary Anatomy: Messrs. James Black, W. B. Clarke, A. P. Gould, C. W. M. Moullin, and R. W. Reid. Elementary Physiology: Messrs. E. H. Fenwick and W. D. Halliburton.

Second Examination. Anatomy: Messrs. W. H. Bennett, R. J. Godlee, H. G. Howse, and Edmund Owen. Physiology: Messrs. W. M. Baker, C. H. Golding-Bird, and J. McCarthy.

Third Examination—Midwifery: Drs. W. Duncan, G. E. Herman, J. B. Potter, and John Williams.

Board of Examiners: Fellowship. Anatomy: Messrs. W. Anderson, R. J. Godlee, H. G. Howse, H. Morris, and E. Owen. Physiology: Messrs. W. M. Baker, C. H. Golding-Bird, B. T. Lowne, and J. McCarthy.

The following Members, having passed the Final Examination for the Fellowship on Nov. 24th, 25th, 26th, and 27th, were, at a meeting of the Council, held on the 9th inst., admitted Fellows of the College:—

Campbell, E. Kenneth, M.B. Edin., Guilford-street; date of Membership, July 21st, 1881.
Dodd, J. Richard, M.D. Durh., Army Medical Staff; July 21st, 1879.
Elliott, J., M.B. Lond., St. Bartholomew's Hospital; July 29th, 1884.
French, George W. Henry, Rose-bank, Highgate; April 23rd, 1884.
Harrison, E., M.B. Cantab., Royal Infirmary, Hull; May 17th, 1883.
Hudson, E., L.S.A., Indian Medical Service (Bengal); July 31st, 1882.
Little, E. Muirhead, L.R.C.P. Lond., Park-street; Jan. 21st, 1880.
Openshaw, T. Horrocks, M.B. Durh., London Hospital; Jan. 17th, 1882.
Page, Harry Marmaduke, L.R.C.P. Lond., Westbourne-park; Jan. 26th, 1885.
Sylvester, George Holden, L.R.C.P. Lond., Dry-hill-park, Tonbridge, Kent; April 16th, 1878.
Tanner, Charles Edward, M.D. Durham, Marlborough, Wilts; Oct. 22nd, 1884.
Vinrace, Felix Coulson, M.D.Q.U.I., 17A, Temple-row, Birmingham; Nov. 11th, 1879.

One other candidate passed the examination, but not having attained the legal age (twenty-five), will receive his diploma at a future meeting of the Council. Fourteen candidates failed to reach the required standard; 4 were referred for six months, and 10 for one year.

The following Members, having passed the Final Examination in May last, and having since attained the legal age, were also admitted Fellows:—

Targett, James Henry, M.B. Lond., Guy's Hospital; Jan. 24th, 1883.
Roughton, Edmund Wilkinson, Brook-green; Jan. 24th, 1883.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Dec. 2nd:—

Brook, William Frederick, St. George's-road, Southwark.
Moxham, Marcus Campbell, Swansea.

AT an inquest held at Weymouth on the 6th inst. on the body of G. W. J. Sutherland, R.N., Deputy Inspector-General, who was found dead under somewhat mysterious circumstances, the jury, in accordance with the medical evidence, returned a verdict of accidental death.

THE annual dinner of the past and present students of the National Dental Hospital was held on the 3rd inst.

THE new Children's Hospital in Bordeaux has just been opened.

ON the 7th inst. a bazaar was opened at Hastings in aid of the Building Fund of the East Sussex Hospital.

ANOTHER outbreak of anthrax in cattle has been reported by the Kent county authorities.

FALL IN THE PRICE OF ANTIPYRIN.—The price of antipyrin has recently fallen from 30*s.* to 5*s.* 6*d.* per kilogramme.

THE death is announced of Mr. R. J. Lupton of Liverpool, after a prolonged illness. The deceased was one of the surgeons to the Hospital for Women of that city.

GRAZ UNIVERSITY.—The University of Graz is celebrating its 300th anniversary. The Medical Faculty, however, was only founded in 1863.

ON the 1st inst. a bazaar, promoted for the purpose of providing funds for removing to larger and more convenient premises the Bradford Hospital for the Sick Children of the Poor, was opened by the Mayor of that town.

ON the 2nd inst. a meeting was held at Gateshead for the purpose of appointing a ladies' committee to assist a general committee in carrying out the proposed scheme for a children's hospital at Gateshead.

ON the 2nd inst. the Earl of Durham opened the new wards at Durham County Hospital, which have been built at an outlay of £6000, part of a bequest of £10,000 made by the late Mr. Eden of Beamish to the institution.

ON the 2nd inst. the Chelmsford Workhouse was burnt down. The buildings were insured for £6500. No lives were lost, but several of the inmates are reported to have had narrow escapes.

SUICIDE OF A MEDICAL MAN IN AN ASYLUM.—Dr. Daschkewitsch, who has written a good deal on nervous and mental diseases in both Russian and foreign journals, has recently hanged himself in a lunatic asylum in Warsaw, in which he had been placed owing to his having developed suicidal tendencies.

ROYAL ALBERT HOSPITAL, DEVONPORT.—From the report which was read at the twenty-third annual meeting of the supporters of this institution, it appears that the average daily number of patients under treatment during the past twelve months has been 71·73, as compared with 76 for the preceding year. The average cost of the maintenance of each occupied bed was £47. 10*s.* 7*d.* The financial condition of the hospital is unsatisfactory, and a reduction of the resident staff of officials is contemplated.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARENDT, FRANK HUGH, L.R.C.P.Lond., M.R.C.S., has been appointed House Surgeon to the Bootle Borough Hospital, vice Martin, resigned.

BAUMGARTNER, HENRY S., M.B., M.S.Dur., M.R.C.S., L.S.A., has been appointed Visiting-Surgeon to the Prudhoe Memorial Convalescent Home, Whitley, Newcastle-on-Tyne.

BONAR, THOMSON, M.D.Edin., has been appointed Assistant Resident Medical Officer to the Royal National Hospital for Consumption, Ventnor, Undercliff, Isle of Wight.

BRENCHLEY, ALGERNON, M.D., C.M.Aber., M.R.C.S., L.S.A., has been elected a Medical Officer of the Camberwell Provident Dispensary, vice H. C. Brenchley, M.R.C.S., L.S.A., deceased.

CALLAGHAN, JAMES LESLIE, L.R.C.S.I., L.R.C.P.Ed., has been appointed Honorary Medical Officer to the Sir G. Bowles Hospital, Butleigh, Somerset.

DOUGLAS, CLAUDE, M.R.C.S., L.R.C.P.Lond., has been appointed Honorary Assistant Surgeon to the Leicester Infirmary.

FIRTH, CHARLES, M.D.Lond., F.R.C.S.E., has been appointed Medical Officer for the Milton District of the Gravesend and Milton Union.

GARROD, ARCHIBALD E., M.A., M.B.Oxon., M.R.C.P., has been appointed Honorary Physician to the St. Marylebone General Dispensary.

GRANT, JOHN, M.B., C.M.Edin., late Assistant Medical Officer to the Inverness District Asylum, Inverness, has been appointed Assistant Medical Officer to the East Riding Asylum, Beverley, Yorkshire.

MACDONALD, JOHN A., M.B., C.M.Glas., has been appointed Medical Officer and Public Vaccinator for the Denton District of the Grantham Union, vice Kingston, resigned.

OLIPHANT, E. H. LAWRENCE, M.D.Edin., has been appointed Assistant Obstetric Physician to the Glasgow Maternity Hospital.

RAYNER, HERBERT E., L.R.C.P.Lond., M.R.C.S., late Clinical Assistant at the London Hospital, has been appointed House-Physician to the above Hospital, vice D. Thomas, M.R.C.S., L.R.C.P., resigned.

TABOR, CHARLES J., M.B., M.R.C.S., L.R.C.P., has been appointed Medical Officer of Health for Illogan District of the Redruth Union, Cornwall.

TURNER, PHILIP D., M.B.Lond., has been appointed House-Physician to University College Hospital.

Births, Marriages, and Deaths.

BIRTHS.

BOVILL.—On the 30th ult., at Redcliffe-gardens, the wife of Edward Bovill, F.R.C.S., Civil Surgeon, Motahari, Bengal, of a daughter.

BROGDEN.—On the 7th inst., at St. Mary-le-Tower Vicarage, Ipswich, the wife of R. W. Brogden, M.B., B.S.Lond., of a daughter.

GORDON.—On the 2nd inst., at Amersham-road, New Cross, S.E., the wife of J. Gordon, M.D., of a son.

GREENFIELD.—On the 2nd inst., at Heriot-row, Edinburgh, the wife of W. S. Greenfield, M.D., F.R.C.P., of a daughter.

HANKINS.—On Oct. 23rd, at Lyons-terrace, Sydney, N.S.W., the wife of G. T. Hankins, M.R.C.S., of Sydney, late of Clapham, London, of a daughter.

LEFTWICH.—On the 28th ult., at Radnor, Park-road, Folkestone, the wife of Charles Harcourt Leftwich, M.R.C.S., &c., of a son.

MARRIAGES.

GEORGE—WANHILL.—On the 25th ult., at St. Peter's, Parkstone, Dorset, George Aldridge George, L.R.C.P. Lond., M.R.C.S., J.P., of Dorchester, to Amy, youngest daughter of the late Thomas Wanhill, Esq., of Poole, Dorset.

LAMB—HEATHERLEY.—On the 18th inst., at St. Andrews, Well-street, London, W., Hugh Lamb, M.R.C.S., L.R.C.P.Lond., of Ashton-on-Ribble, Lancashire, to Lois, only daughter of T. Heatherley, Esq., of Newman-street, W.

DEATHS.

DREW.—On the 1st inst., at Cheltenham, Samuel Drew, M.D.Aber., aged 66.

HUMBY.—On the 6th inst., at Brunswick-road, Hove, Brighton, William Warren Humby, M.R.C.P.Lond.

JONES.—On Sept. 28th, at Rugby, Morgan County, State of Tennessee, U.S.A. (of dysentery), Alfred Jones, M.D., aged 45.

MACKENZIE.—On Oct. 14th, at Lyons-terrace, Hyde-park, Sydney, N.S.W., Walter Fawkes Mackenzie, L.R.C.P.Ed., M.R.C.S., L.S.A., aged 51.

PHILLIPS.—On the 2nd ult., at Jamaica (of fever), John Mortlock Phillips, M.D., Surgeon of H.M.S. *Goshawk*, aged 26.

UMPLEBY.—On the 2nd inst., at South-parade, York, Henry Umpleby, M.D., late of Bedale, aged 71.

WILTSHIRE.—On the 4th inst., Alfred Wiltshire, M.D., F.R.C.P., of Wimpole-street, aged 47.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, December 13.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

SOCIETY OF ARTS.—8 P.M. Mr. Lewis Foreman Day: The Principle and Practice of Ornamental Design (Cantor Lecture).

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Keser: A case of Intra-peritoneal Hæmorrhage in a new-born Child.—Mr. Marmaduke Sheild: On the Administration of Ether, and on the Selection of Anæsthetic Agents in Surgical Operations.

Tuesday, December 14.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE LATE DR. ROBERT RIDDELL.

Dr. Joseph Rogers, president of the Poor-law Medical Officers' Association, writes to ask for the practical sympathy of the profession on behalf of the widow and family of the late Dr. Robert Riddell. Dr. Rogers' state of health will not permit him to take an active part in the matter, but he states that Mr. Wickham Barnes, F.R.C.S., of 3, Bolt-court, Fleet-street, has kindly offered to receive subscriptions in aid of the bereaved family.

Mr. F. Shaw.—Dr. G. V. Poore's work on Medical Electricity, or Amidon's Electro-Therapeutics.

A. M. G.—The lines are not suitable for our columns.

"CRACKED OR FISSURED TONGUE."

To the Editor of THE LANCET.

SIR,—Your correspondent, "Young Practitioner," does not mention whether his patient is suffering from constitutional syphilis or not. If not, I think he will find the following treatment of use:—℞. Acidum broscicum, ʒi.; aq. ad ʒiii. This lotion for the tongue to be used frequently. The above, together with a tonic containing iron in some form, I have found sufficient to cure this very troublesome disease. The diet should consist principally of milk and potash water, with very little solid food, if any.

I am, Sir, yours faithfully,

December 2nd, 1886. JAS. EWING HUNTER.

THE DEATH-RATE OF ALDERSHOT.

WE are asked, probably in view of our previous comments on diphtheria in Aldershot, to note the fact that during the month ending Nov. 30th the mortality for this urban district was only at the rate of 8 per 1000. We make it a general practice not to call attention to death-rates for short periods on comparatively small populations, and we can only comply with the request made on this occasion subject to the caution that unless a small death-rate in Aldershot is maintained the one quoted has no real significance. And not only so; but if any part of the camp, with its picked body of able-bodied troops, is in any way included in the population on which the rate is calculated, it is even more misleading for any purposes of comparison.

M. O. H.—By application, in the first instance, to the Secretary of the Board.

THE IRISH CONJOINT EXAMINATION SCHEME.

Mr. Thomas Laffan (Cashel) writes to complain of a regulation under this scheme which renders it compulsory for students who have been able heretofore to work out their first year's study outside a medical school to now enter a place of study immediately after matriculation. This rule our correspondent regards as an act of injustice to the whole provincial profession, who are affected by it; and he asks what steps the newly elected representative for Ireland will take to remedy it.

Local Board.—There is no legal objection to one partner acting as an officer while the other is a member of the local board, provided they both be properly qualified—the one as a member of the board, the other as an officer. Of course, no private agreement between themselves, such as we understand to be meant, is a matter which concerns the electors.

F. H. H. (Nottingham).—A pledget of wool saturated with sweet oil, kept constantly applied, is often very effective.

Dr. J. Fraser.—In an early number.

PROFESSIONAL TITLES.

To the Editor of THE LANCET.

SIR,—The question of titles, which sounds the best and is worth the most, still agitates the profession, and crops up in your correspondence columns occasionally. Cannot the new Council give us some distinct legislation on the subject? At present there is no guide as to the title of "Dr." but that of taste, and in matters of taste it is not to be disputed. The Edinburgh College of Physicians takes the position that the title of "Physician" is allowable to its licentiates, but discourages, while not forbidding, the use of the title of "Dr." This position will lead ultimately to that title being used by all the licentiates. It will become simply a matter of self-defence, unless the title be restricted to a degree equivalent to that of the London University "M.D." The practitioner who wishes to preserve the rules of good taste finds himself thrown into the midst of a large number who think quite differently as to what good taste is, and in self-defence he adopts the general view. The physician and surgeon (or as one of your correspondents playfully and kindly calls him the quasi-physician and surgeon) finds himself competing not only with licentiates who think it right to assume the title of "Dr.," but also with M.B.'s and C.M.'s who are really only doubly qualified general practitioners, after all; but who, if they do not assume the title prematurely, can become M.D.'s by writing a thesis, often of but little merit as an original production. The subject is really important, and is at the bottom of much of our jealousy of each other. It will never be finally settled until the profession has one portal and one title, or titles which define particular grades and lines of practice. It appears to me that too much is thought of titles and of examinations. The first ought to be certificates of proficiency, not ornamental distinctions; the second ought to be tests of proficiency, not of the power of cramming. To be true tests of proficiency, the examinations must be longer, and include more practical work, especially in the clinical department. I do not say that honours in examination or prizes are undesirable. These ought to be the reward for more than average merit, not a distinction of title, which causes innumerable jealousies, and which the British public, for the protection of which the whole system exists, will never really understand.

I am, Sir, your obedient servant,

Loughborough, Dec. 4th, 1886. J. B. PIKE.

PATENT MEDICINES IN RUSSIA.

A LIST of patent medicines, the importation of which the Russian Government has decided to prohibit, has recently been published. It consists of about 800 preparations of English, American, French, and German origin, the English or American numbering nearly 100. Pills, plasters, hair restorers, cough drops, medicated foods, ointments, and many miscellaneous preparations for a great variety of purposes are all classed together in one long medical *index expurgatorius*. The list appears to have been drawn up by a committee of Russian physicians, and even such remedies as taraxacum and podophyllin have been struck out.

Dr. Schiltz.—The treatment of whooping-cough by carbolic acid has been long adopted in this country.

"DEAD FINGERS."

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 4th Dr. J. Edward Squire says that local syncope, or "dead fingers," is probably due to spasm of the arterioles. This explanation is, I think, correct as far as it goes. It would be interesting to know whether "dead fingers" occur in extreme old age. This inquiry is suggested by the following case. On May 28th, 1884, I saw an old gentleman aged ninety-one. His intellect was quite clear, sight good, and hearing fair. He told me he used to suffer very often during his lifetime from dead fingers, and that the affection used often to come on without any known cause. It always occurred when he bathed in the sea, save on one occasion. During the last fifteen years he has never had dead fingers. This may possibly be due to the nerves supplying the arterioles becoming dulled by age.

I am, Sir, your obedient servant,

Burt, Londonderry, Dec. 4th, 1886. E. DONALDSON

ALGERIAN COLONIAL SURGEONCIES.

A BELGIAN practitioner, who complains that he lives in a poor district where eight or ten years ago there was only one medical man, there being now eight, and where they, as he says, "se disputent littéralement un morceau de pain," decided to take M. Barella's advice about emigration to Algeria, and wrote to a prominent Algerian deputy for information. The answer he received is exactly what we anticipated in a notice in our last issue (p. 1109)—viz., that foreigners cannot be appointed to medical posts in Algeria, and that there are at least twenty French candidates, many of them, indeed, natives of Algeria, who are most anxious for the post of colonial surgeon, but the vacancies are very rare, and the service is being gradually reduced; for as the population increases in the different localities, so as to be sufficient to need the services of a medical man, the Government withdraws the grant for the pay of a colonial surgeon.

Mr. Henry Love, M.B.—Our correspondent should have declined the subpœna unless a fair retaining fee were offered him. In any case, five shillings could not be considered in any way an adequate recompense for the inconvenience of attending a court. Failing a proper fee, our correspondent might have intimated that inasmuch as he would be called to give an opinion, and not merely state matters of fact, his evidence might not be of any great service to the parties demanding his attendance. Did our correspondent before he was sworn appeal to the judge for further remuneration? Even when the costs are taxed a medical man is allowed a larger sum than that received by our correspondent. If the case is settled, there is, we fear, no legal redress.

Enquirer.—C is quite justified in refusing to make social calls for professional ends.

Dr. Augagneur (Lyon).—We cannot exchange.

MEDICAL ATTENDANCE ON THE POOR.

To the Editor of THE LANCET.

SIR,—On this subject, as on most others, an ounce of fact is worth a pound of theory; and I wish to show by means of the former that this question can be, and is being, solved in a manner satisfactory both to the profession and the poor. Some five years ago the Wandsworth Medical Aid Society was started by several gentlemen, most of whom were connected with the oldest established practices in the place. The basis of the society is purely provident; the payments consist mainly of the much-despised penny a week; the members select their medical attendant, come to his surgery, and are considered in all respects as his private patients. The number of members at the present time approaches 5000; the annual income is nearly £1000, divided among six medical attendants; the expenses of collection, printing, &c. are about 15 per cent., and the average rate of sickness is 5 per cent.

I am, Sir, your obedient servant,

Dec. 7th, 1886. W. G. DICKINSON.

To the Editor of THE LANCET.

SIR,—In reference to the letter of Mr. T. Holmes in your issue of the 4th inst., I beg to be allowed to make a few remarks about the "bogus" dispensaries to which he alludes. The cause of the great number of these private dispensaries in London is due to the fact that there is apparently no restriction placed on, or proper inquiries made as to, the social status or the means of the patients who present themselves for treatment at most of the hospitals and charitable institutions. So the private practitioner is obliged to give advice and medicine for a sum less than what it would cost in time and fares to attend a hospital. In a thickly populated metropolitan district with which I am well acquainted it is almost an impossibility for any medical man to support himself, as he has to compete with several hospitals and charitable dispensaries; together with his professional brethren who accept the modest sum of *one penny* per week for attendance and medicine whenever their services may be required.

It may be of interest to some of your readers, especially those who talk about the nobility, status, etiquette, &c., of the profession, to know that one penny per week is quite a large fee when compared with those that obtain in most of the mining districts of England and Scotland, where the medical gentleman attends whole families within a three- or four-mile radius for in some places 2*d.*, and in others 3*d.*, per week, paying 10 per cent. for the collection.—I am, Sir, yours faithfully,

Dec. 7th, 1886. TWIDDLER.

THE INFLUENCE OF CLIMATE AND SOIL UPON MEDICINAL PLANTS.

ACCORDING to Professor Vogel, plants do not always contain their characteristic alkaloids when grown under other than natural conditions. Hemlock does not yield coniine in Scotland, and cinchona plants are nearly free from quinine when grown in hothouses. Tannin is found in the greatest quantity in trees which have had a full supply of direct sunlight.

Dr. Leibreicht (Liège).—We do not, at this distance of time, recollect the name of the writer of the letter referred to.

B. B. K.—There can be no objection to a card so worded.

Dr. Craig-Smith.—Nine [illegible]

THE ABUSE OF MILK DIET.

M. DEBOVE showed a case the other day at a Paris medical society which demonstrated the possibility of pushing a milk diet too far. The man was of very intemperate habits, and had gastric ulceration, for which he was put on a milk diet in a country hospital. At first he took only about two quarts a day, but this quantity was gradually raised to eight quarts. He became greatly emaciated, and was found to have a stomach enormously dilated. The milk was reduced to three pints, and powdered meat added, the stomach being washed out every day. Under this he rapidly improved, scarcely any splashing sound being audible over the epigastrium after meals.

Mr. R. D. Stapylton.—We do not know that a duplicate diploma is ever issued; but probably some evidence would be afforded, after due investigation, of qualification. Our correspondent should apply to the officials of the board who granted the diploma.

M.D. (Paris).—Is our correspondent's patient living in an arsenically impregnated atmosphere?

Alpha.—The nurse of the ward, who is supposed to be equal to her duties.

Dr. Schmulewitsch.—We are unable to comply with the request.

THE DEAF AND DUMB.

To the Editor of THE LANCET.

SIR,—In the absence of inquiry into the cause of deaf-mutism in 80 per cent. from disease of the so afflicted, and of my receiving reply from the Royal Commissioners now sitting thereon, would you be pleased to insert the enclosed copy of a letter in your columns. The enclosed appeal in behalf of the deaf and dumb, although it was written thirty years ago, is good now, and requires scrutiny, and is much strengthened by much correspondence and reflection on the necessary and essential point of inquiry by the said Royal Commissioners, as the deaf and dumb are entitled to our sympathy as much as any other sufferers of mankind from disease. I am, Sir, faithfully yours,

Bath, Dec. 4th, 1886. WILLIAM PARKER, M.R.C.S., L.A.C.

The Lord Egerton, Chairman Royal Commission on the Blind, the Deaf and Dumb, &c., Westminster, London.

MY LORD,—May it please your lordship to lay before the above Commission the three accompanying pamphlets, containing my researches and practice on the deaf and dumb for fifty-six years, during which time I have mixed with some of the most celebrated aurists in Europe—viz., M. Itard in Paris, in 1830; Dr. Purdon, of the Belfast Deaf and Dumb Institution, &c., who concur in my proposition that a hospital should be founded for their benefit. "Precept upon precept," &c., have been observed in my labours among authors, the most distinguished in chemical and medical sciences. My object has not been to interfere with any system of teaching, but in their cure, which is too palpably neglected. As M. Pinel, about the year 1825, liberated the lunatic from his chains, after repeated appeals to the French Government, so the deaf and dumb should be freed of disease, 80 per cent. being the frightful number of the so afflicted. No attempt to cure them in a hospital has been made. Should such be refused to them in this professedly religious country? This appeal is submitted to you for your deliberation and recommendation to the English Legislature to establish an especial hospital in Bath, where they would receive the benefit of those very valuable hot mineral waters (see pamphlet, "Lecture in behalf of the Deaf and Dumb," in 1856.—I have the honour to be, my lord, your obedient servant, WILLIAM PARKER, M.R.C.S., L.A.C.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir W. W. Gull, London; Dr. W. H. Dickinson, London; Dr. Russell Reynolds, London; Dr. Macalister, Cambridge; Dr. Allchin, London; Sir Henry Thompson, London; Dr. W. O. Priestley, London; Dr. De Havilland Hall, London; Dr. Latham, Cambridge; Sir Andrew Clark, London; Dr. Tomes, Midnapore; Dr. Hughlings Jackson, London; Dr. Percy Boulton, London; Dr. Charlton Bastian, London; Dr. Broadbent, London; Dr. Hime, Bradford; Mr. Bellamy, London; Lord Stanley of Alderley; Dr. John Lucas; Dr. Bristowe, London; Mr. Brown, London; Mr. S. Snell, Sheffield; Dr. Grabham, Pontefract; Mr. E. T. Collins, London; Mr. T. Laffan, Cashel; Mr. W. Fraser, Ashburton; Mrs. Weldon, London; Dr. J. F. Porter, London; Dr. C. R. Drysdale, London; Dr. Schmulewitsch, St. Petersburg; Mr. R. d'Heureuse, New York; Dr. J. B. Sim, Nottingham; Mr. Foster, Aldershot; Dr. Greig Smith, Clifton; Dr. Mercado, Aden; Dr. Muskett, Sydney; Mr. H. Rundle, Southsea; Dr. Augagneur, Lyon; Mr. J. E. Hunter; Mr. W. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris

ABSTRACT OF THE

Brown Lectures.

Delivered at the University of London,

By VICTOR HORSLEY, F.R.C.S., F.R.S.

THE PATHOLOGY OF THE THYROID GLAND.

LECTURE I.

IN the lectures delivered last year on the pathological relations of the thyroid gland, evidence was adduced tending to show that this body was an excretory or rather metabolic organ, without being provided with the usual duct of such organs. It was also shown that the gland possessed some sort of hæmapoietic function, since the number of red blood-discs in the efferent vein was greater than their number in the afferent artery. Whether the gland exercised any power of forming the fluid portions of blood must remain at present a doubtful matter. Hitherto it had been held that the gland was a maker of corpuscles only. But blood is not a definitely complete or finished tissue like muscle or nerve; at the same time it is not a mere carrier of oxygen, food, and excreta. The ease with which blood when lost can be replaced in the organism was an important and suggestive circumstance. Blood may be regarded as an intermediate tissue, and it is interesting to remember its embryonic origin from the connective tissue cells as shown by Schäfer and others. It is an intermediate tissue also in serving to unite in itself all the requirements of every other tissue. Probably the thyroid gland is hæmapoietic as the result of some metamorphosing influence it may have on the fluid constituents of the blood. Last year it was apparently demonstrated also that it was a direct corpuscle-maker. The subject that treated of the manufacture of blood-corpuscles was, however, always a difficult problem, and especially so when the rapid way in which they were regenerated after acute losses of blood is considered. But some remarkable researches made by Wooldridge might throw a flood of light on this dark question. Indeed, the notion of Wooldridge that the blood-plasma was but a mass of fluid protoplasm from which corpuscles might be precipitated in the fashion of a spontaneous generation should be regarded as a revolutionary idea, but nevertheless as one deserving of careful consideration. There could be no doubt, however, that Wooldridge's observation, to the effect that the mere action of cold upon corpuscle-free blood-plasma could produce a precipitate of biconcave discs, was a perfectly true and faithful observation, which had been attested even by the great Virchow himself. So that whether we go with Wooldridge or not in believing that blood-plasma was fluid protoplasm, we must recognise the value of his important discovery. Taking the observation of Wooldridge as a lever, we might argue that the thyroid gland may possess a cytopoietic function in an indirect fashion, the blood-discs being precipitated from the fluid blood-plasma by some method as yet unknown. But this was only thrown out by way of suggestion, and Mr. Horsley did not mean to imply anything further than that such a process might be part of the hæmapoietic function of the thyroid gland.

The next subject discussed was the histology of the thyroid glands. The acini were well-known microscopic objects, but not so the embryonic tissue, which had been described by Cresswell Baber, and which Mr. Horsley had specially investigated. This tissue was composed of columns of cells round which blood capillaries coursed; hence it had a mesh-like aspect. In some animals a large quantity of this tissue could be formed in a single lump beneath the capsule. This lump of embryonic tissue was also separately and distinctly encapsuled. Virchow considered that such a lump might be the homologue of a single acinus; but the Brown Professor could not accede to this position. Although the tissue was regarded as embryonic, still it had not been demonstrated that this tissue ever developed into acini; on the contrary, the result of researches into this matter had hitherto rather tended to oppose the likelihood of such a supposition being true. Of the nature of the large parenchymatous cells described by Weber we were equally also in the dark. These views were also borne out by the observations of Stieda on the development of the thyroid gland. That these nodules of "embryonic" tissue were not only imperfect developments of thyroid tissue was also rendered probable by the fact that the nodules, instead of becoming further metamorphosed, increased in size, number, and staining power when the thyroid gland underwent development as the result of removal of one lobe. This operation of removal of the lobe may be carried out in dogs by the exercise of antiseptic precautions, and the animal may be then kept alive for a great number of days. In one case in which Mr. Horsley had operated the animal was killed after the lapse of 160 days from the operation. The animal was a young adult bitch, and had exercised the functions of a parent, increasing in weight and size during that period. The lobe of the gland that was left became hypertrophied so as to be four or five times its normal size. One of the most remarkable features of the thyroid hypertrophy was the great vascular engorgement, which was probably in relation to the increased amount of hæmapoietic function which would be thrown upon it so long as there was no emaciation of the animal. If the animal wasted after the removal of the lobe of the thyroid gland, then there need be, and probably would be, no hypertrophy of the remaining lobe.

Mr. Horsley discussed minutely the histology of compensatory hypertrophy of the kidney, and showed that hypertrophy in this case was also at the command of the body weight. If this did not increase, and if there was actual loss of weight, the compensatory hypertrophy of the remaining kidney did not occur. This matter of increase or diminution of body weight gave a clue to much of the want of harmony that existed on the subject of compensatory hypertrophy; and Lorenz, in a recent number of the *Deutsches Archiv*, had pointed out the great importance, and indeed deserved to receive much credit for insisting on the importance, of the matter. Remembering, then, that compensatory hypertrophy might not occur if the animal did not keep up its weight, Mr. Horsley proceeded to demonstrate the histological facts of renal and thyroidal compensatory hypertrophy. The renal enlargement was both macroscopic and microscopic. The cortex was more hypertrophied, far more than the pyramids, and the hypertrophy was chiefly seen in a greater size and a greater number of the vascular glomeruli, in the greater size of the lumina of the convoluted and straight tubules, and in a hyperplasia and hypertrophy of the epithelial cells lining the convoluted tubules. The connective tissue did not appear to be increased in amount. In hypertrophy of the thyroid the acini were found to undergo very remarkable changes; the epithelial cells lining them multiplied in number and increased in size, so that there was a plication of the acinal wall; but the full reason for this folding-in of the wall of the acinus, Mr. Horsley said, was not yet forthcoming. There was no increase in the number of the parenchymatous cells of Weber, and no metamorphosis of the "embryonic" tissue into acini. The change that occurred in the contents of the acini was not the least striking feature of the alterations. The colloid material did not increase in amount, but changed its consistence, became softer, more viscous, and less solid; so that at one time it appeared like a network of viscosity, and later on had a watery aspect in which floated a few granules. Increased activity of the organ appeared, therefore, to cause a diminution in the consistence, and this was contrasted with the greater solidification of the acinal contents that occurred when the function of the gland was less active.

LECTURE II.

Relation of the Thyroid to the Encephalon.—The question of the relation of the thyroid gland to the cerebral hemispheres has been discussed by Luschka, Liebermeister, Guyon, and others. Most of these observers believed that the thyroid gland acted as a kind of bolster to support the circulation to the brain, and they attributed the nervous disturbances that followed the extirpation of the organ to the removal of its mechanical support or function. John Simon, however, somewhat modified this view, and believed that the thyroid gland might serve as a drain to relieve the cerebral hemispheres from much pressure, and he

also thought that it was a special source of nutrition to the brain in such a way as that each lobe had some relation to each hemisphere of the same side. Mr. Horsley believed, however, that the relation of the thyroid gland to the brain was an apparent and not a real one, and experimental evidence was adduced to prove this position. An adult fox terrier, from whom one lobe of the thyroid gland was removed, was submitted to experimental excitation of the cerebral hemispheres after the expiration of a period of 271 days. An adult black-and-tan dog was similarly the subject of an experiment 109 days after removal of one lobe of the thyroid; also a bonnet monkey eighty-four days after a similar operation. The motor centres of each of these animals were exposed under precisely similar conditions. Excitations with the faradaic current were made to each motor part of the hemisphere in each animal, and with the result that no difference could be detected on the two sides. The period of latency, tonic spasm, and clonic spasm—epileptic motor phenomena—were precisely the same whether the right or left hemisphere was stimulated. It was clear then that removal of the one lobe of the thyroid had exerted no detectible influence over the nutrition of the motor cerebral centres on the same side. German workers in this department had come to the conclusion that the thyroid gland had a special metabolic function over those waste products which were specially inimical to the nervous system, and especially the brain. This view was put forward in order to explain the rapid onset of nervous symptoms, which were the most noteworthy and earliest symptoms in many of the animals from whom the thyroid gland had been wholly extirpated. Mr. Horsley said that he would adopt this view, but only in a tentative way.

Innervation of the Thyroid Gland.—Mr. Horsley stated that there was no experimental or clinical evidence that the thyroid gland is represented in the cerebral hemispheres. The gland receives from the medulla oblongata sympathetic fibres, which pass down the cervical part of the spinal cord as far as the eighth cervical nerve, and then leave the cord and proceed upwards in a direction almost parallel to their former direction in the cord, and are distributed to the glands along the arterial vessels. The gland appears also to receive nerve fibres from the recurrent laryngeal nerve, which are probably derived from the motor nucleus of the spinal accessory. Dr. Hale White had advanced the theory that the recurrent laryngeal nerve was the trophic nerve of the gland. This view was based on the observation of two cases of disease in which the recurrent laryngeal nerve had been compressed by the pressure of an aneurysm in one case, and by the slow growth of a tumour in another, and in both of which there was atrophy of the gland on the side on which the recurrent nerve was damaged. Dr. Hale White, however, also published a third case of tumour of the base of the brain, in which the vagus nerve was involved, but in which there was no atrophy. It was suggested by him that the trophic fibres of the thyroid gland joined the recurrent nerve lower down than the seat of the tumour in this third case. Mr. Horsley pointed out that in the first case the sympathetic fibres going to the thyroid gland must have been affected, and that they may have been involved in the second of Dr. White's cases. He himself believed that the gland was chiefly supplied by the sympathetic nerves; that the sympathetic was the "secretory" or "glandular" nerve. The facts relating to the submaxillary gland were adduced in support of this view, and it was thought that the "secretory" nerves of the thyroid were contained in the sympathetic in the same manner as the "secretory" fibres of the chorda tympani were arranged in the nerve-supply to the submaxillary gland. In order to place on an experimental basis the subject of innervation of the gland Mr. Horsley had performed two experiments on dogs. In each dog an inch of the recurrent laryngeal nerve was excised on one side. One dog was kept alive nine and the other eleven months. But there was no histological difference to be detected between the lobes of the thyroid in either case. Schiff had made some incomplete experimental observations on the influence of the sympathetic nerve on the thyroid gland. He had torn through all the sympathetic nerve fibres going to the gland on the coats of the arteries. This, though a tedious, was a possible operation. As the result of it, Schiff detected no change in the nutrition of the gland, except the unavoidable hyperæmia. But as Schiff did not keep the animals alive for longer than a few days, [illegible] a much longer time to become manifest, Mr. Horsley considered that we must await the result of further investigation before coming to any conclusion concerning the influence of the sympathetic nerve-supply.

Comparative Pathology of the Thyroid Gland.—The Brown Professor next took up the subject of the relation of the thyroid gland to the metabolic processes in different kinds of animals. The first problem was to estimate the importance of the gland to the body processes in the various classes of animals. This was altogether a very wide field, and one which he had but just begun to explore. Indeed his observations had been largely interrupted in this direction by the more pressing investigations in relation to rabies. But he had, nevertheless, obtained results of a sufficiently clear nature to show that the gland possessed a very different activity in different animals. This difference was expressed not only anatomically, but also pathologically. Moreover, there was an exact proportion between the activity of the gland and the symptoms that followed its removal. The exact proportion obtained in this way: The greater the activity of the gland in any particular animal or class of animals the more urgent and rapid were the symptoms that followed its removal; and, conversely, the less the activity of the gland the longer the animal lived without symptoms. The relation, however, on which Mr. Horsley specially insisted at the present time was the anatomical one. In the donkey the thyroid consists of two small lobes unconnected by an isthmus. Not only were the glands very small to the naked eye, but the acini of which they were composed were also very minute and numerous, and contained but little colloid material in their interiors. The suggestion was made that where the glands and acini are small functional activity is slight. One experiment was made on a donkey. The thyroid gland was excised in August, 1885, and the animal died in 205 days, or about seven months. The chief symptoms for two months were emaciation and weakness; the mental hebetude, if any, was difficult to gauge; the temperature of its body was but slightly lowered. In March, 1886, when the weather became severely cold, nervous symptoms suddenly supervened, and tremors were observed for three days, chiefly in the muscles of the head and neck. On the fourth day these were complicated by constant twitching; the animal became so weak as to be unable to stand, and the body temperature became markedly lowered. Later still muscular rigidity was observed, and also the paralysis increased, especially in the jaw. On the fifth day of the cold weather the donkey became much worse, and died in the morning. This experiment seemed to show that the gland in the donkey was of but relatively little importance, and the case also brought out very clearly the malignant influence of cold when the thyroid gland was inactive or had been altogether removed. Two experiments had been made in sheep, which have a comparatively good-sized thyroid gland, but though the operation was performed in October, 1885, the animals were still well. It was impossible, however, to say yet whether the whole of the glands had been removed. In two pigs the removal of the thyroid was followed by characteristic symptoms of tremors, leucocytosis, and anæmia, with subnormal temperature. The duration of the incubation period in these animals was probably rather a long one, but uncertainty may be caused by accidental circumstances. In monkeys the symptoms supervened fairly rapidly after removal of the gland, especially in cold weather, and in young animals. In cats also the symptoms soon became evident, and this was even more marked in the cases of young adult dogs. In the last three sorts of animals the glands were fairly large, and so were their acini. The whole subject, however, required further investigation.

SURGICAL APPLIANCES AND THE HOSPITAL SATURDAY FUND.—The committee which was appointed last January by the Board of Delegates of the Hospital Saturday Fund to carry out an extension of this fund's usefulness—viz., the provision of surgical appliances and instruments at one-half the contract price to cases recommended by such fund collectors—have just made a report of their work to the end of their financial year, Nov. 30th. Assistance has been afforded to 632 cases, the average cost being 6*s.* 8*d.* for each appliance. The expenditure has amounted to nearly £360, of which patients have paid £160. A balance remains of £160.

DISLOCATION OF THE HIP.

BY HENRY MORRIS, M.A. LOND., F.R.C.S. ENG.,
SURGEON TO, AND LECTURER ON SURGERY AT, THE MIDDLESEX HOSPITAL.

MY attention has been directed to a lecture by Professor Humphry in THE LANCET of Nov. 27th, 1886, on three cases of hip dislocations. In his remarks the lecturer says: "It has lately been maintained, upon insufficient grounds I think, that the dislocations of the hip backwards are always, or almost always, indirect; that the head of the bone escapes from the acetabulum close to the transverse ligament, and is then, if the limb be in an inverted position, carried backwards, and perhaps upwards. Furthermore, it is held that the accident occurs during the *ab*ducted position of the limb." Professor Humphry's authority on anatomical and surgical matters is so well recognised that any views published by him are likely to be accepted by the majority without hesitation or question. It is for this reason that I venture to point out, with due respect for the weight of his opinions, wherein there is ground for differing from his conclusions.

I will, as briefly as possible, first state how very nearly the views which I have published correspond with those which Professor Humphry seeks to disprove, and upon what kind of foundation my views are based.

Ten years ago, when demonstrator of practical surgery, I found myself expected to teach that the "backward," or (as Hamilton calls them) "backward and upward," varieties of the four regular dislocations—namely, the dorsal and the ischiatic—were always produced by violence applied to the limb when in a flexed and *ad*ducted position; that in these dislocations the head of the femur reached its new position by being driven there *directly* through the back of the capsule; that the head of the bone often escaped through a mere buttonhole in the capsule; and that in the dorsal dislocation it always passed out above the tendon of the obturator internus. This teaching, venerable and authoritative as it is, seemed to me so inconsistent with the anatomical construction of the joint, and with the magical ease with which dorsal and ischiatic dislocations are reduced by manipulations—i.e., by movements which simply bring the head of the femur down to the lower and shallow edge of the acetabulum, and then turn it upwards into its socket through the rent here situated,—so inconsistent, too, with the facility with which pubic and obturator dislocations can be converted into dorsal, or dorsal and ischiatic into pubic, that I was induced to investigate for myself.

My inquiries were directed first to the anatomy of the joint, and to the results of experiments on the dead subject, but they by no means ended there. I carefully studied the descriptions of published cases, and the contents of many museums, both British and foreign: and in course of time I published no less than five cases of traumatic dislocations of the hip, which had been under my own care,[1] besides the description of another, the dissection of which was made under my own observation. This I believe to be a somewhat larger experience than usually falls to the lot of one surgeon within a period of five or six years. Moreover, I have since had the advantage of witnessing the dissection of a seventh case, an account of which was published by Mr. Hulke, in a lecture in THE LANCET. I hope, therefore, I have not allowed myself to infer too much from experiments on the dead body. Certainly, I have taken pains to check and, where necessary, correct the inferences I drew from such experiments, and to obtain from all these sources put together sufficient grounds for the opinions I maintain. Some of these views I may shortly sum up as follows:—1. In the regular backward dislocations (i.e., dorsal and sciatic) the head of the femur leaves the acetabulum in a downward, or downward and backward, direction through a rupture in the thin parts of the capsule, and is carried upwards outside the acetabulum to its position on the dorsum ilii or ischium. In other words, that these dislocations (when not complicated with fracture of one or both bones of the joint) are indirect in the sense that the head of the bone ascends to its position after having burst through the capsule at a lower point. 2. That the thin part of the capsule is all that portion of it, except the narrow pubo-femoral band, which is below and between two imaginary lines—namely, one drawn from the inferior iliac spine to the small trochanter, and the other from the upper part of the tuber ischii to the digital fossa of the femur. 3. That during *ab*duction the head of the bone bulges against the thin portion of the capsule, and that in this position dislocation most easily occurs. 4. That the mode of occurrence of backward dislocations described in No. 1 affords the only rational explanation of the ease with which dorsal and sciatic dislocations are reduced, or converted into the pubic variety, by manipulation.

After refuting the statement that dislocations backwards occur in the living body during *ab*duction, Professor Humphry states the following to be some of the points to which he specially wishes to direct attention: "1. The position of the rent in the capsule through which the head of the bone escapes from the acetabulum—namely, at the lower and back part, behind the pubo-femoral ligament, therefore not at the lowest part, although the weakness of the capsule here may seem to predispose it to give way in this latter situation. 2. That the dislocation occurs commonly, not, as recently suggested, when the limb is abducted, but when the thigh is adducted, flexed, and inverted. 3. That the dislocation is not indirect, but direct, the head of the bone being driven through the rent in the capsule at the lower and back part of the joint, and then carried up to a variable extent by the force which caused the dislocation." If I might change the positions of the two words, indirect and direct, in No. 3, I could agree substantially with Professor Humphry's first and third conclusions. From the second I entirely dissent. On a fourth point I entirely agree with him, for he gives precisely the same *rationale* of the reduction of manipulation which I insisted upon—namely, that the head of the bone is *carried down* opposite to the rent in the capsule before any effort is made to turn it back into the acetabulum. Respecting the first conclusion, I submit that the lowest part of the capsule is behind the pubo-femoral ligament, and that in backward dislocations by *ab*duction it is not necessary, though it is not unfrequent, for this band to be either detached or ruptured. As a proof of the latter part of this statement, take the following description of the rent in the capsule in a case of dorsal dislocation during abduction, figured in my paper in the Royal Medical and Chirurgical Transactions for 1877. Place side by side with this the description of any one it matters not which—of the three cases given in Professor Humphry's lecture. I will take the first, because it is the first, and is described as a case of dislocation on the dorsum of the ilium.

Case published in 1877.	*Prof. Humphry's Case.*
"The rent commenced below the pectineo-femoral band, midway between the acetabulum and the femur, and ran (1) outwards and backwards to the neck of the latter, which it reached just above and behind the small trochanter, and (2) inwards and backwards across the thin portion of the capsule towards the acetabulum, which it nearly reached, a little behind the ischial border of the cotyloid notch. It thus formed two sides of a large opening, which was made quadrilateral in form by the detachment of the flap from the back of the femoral neck."	"There was a valvular rent in the under and back part of the capsule, commencing just behind the pubo-femoral ligament, midway between the acetabular and the femoral attachments, as a single tear, which divided and extended upwards and backwards to the tuber ischii, and upwards and forwards to the trochanter near the attachment of the obturator externus; or it might be described as a tri-radiate rent, the rays diverging from the apex of the valve which was situated opposite the lower part of the tuber ischii."

Allowing for difference in phraseology, it will be seen that the rents in these two capsules were essentially the same. In both cases, by rising on to the dorsum ilii the head of the bone reached a much higher position than that at which it was forced through the capsule; therefore in both cases the position attained was *secondary* and by an *indirect* course. In his second case the head of the bone did not mount up so high, and the dislocation was therefore less *indirect*; it was, however, neither a dorsal nor an ischiatic dislocation, but, as Hamilton calls it, an "irregular" dislocation, *downwards and backwards*, upon the tube[illegible] form of dislocation simply cor[illegible]dislocation of dislo[illegible]n, to refute

[1] Royal Medical and Chirurgical Transactions, vols. lx. and lx[illegible]

them, I do not understand. The third case was a "regular" ischiatic dislocation or "dorsal below the tendon," and the rent in the capsule was such as I have produced any number of times by abduction; it was entirely confined to the thin part of the capsule.

Indeed, all three of Prof. Humphry's cases afford strong confirmation of my view as to the position of the rent in the capsule in hip dislocations. It would be almost impossible for any cases to correspond more completely than they do with my published description of the usual lesions of the capsule—namely, that the rent is confined to its thin portion, and takes a general course along the femoral attachment of this portion.

I am unable, within the limits of this paper, to discuss all Professor Humphry's arguments in favour of his second conclusion; but I cannot see that his cases afford any evidence whatever in support of it; on the contrary, two of them—the first and third—point to *ab*duction as having been the position of the limb at the time of injury, for a boy aged thirteen, riding on the back of a horse in a cart, and falling astride the shaft, and a man in the act of excavating a bank part of which falls upon him, are pretty certain to have their legs well separated. As to the position of the limb in the second case nothing can be inferred, because all that is said about it is that a lad aged thirteen was run over by a heavy cart. It is often impossible to learn what was the exact position of the patient when dislocation occurred, but in not a few published cases in which it is stated that the thigh was adducted, a careful consideration of the account given shows reasons for thinking that it was *ab*ducted. Referring to the position of the limb, Professor Humphry says "The probabilities, of course, are that a limb will be in a habitual or natural position when an accident occurs, and the position of flexion, *ad*duction, and *in*version, is both a habitual position, and is the one in which the head of the femur is pressed against the part of the capsule (the under and back part), and this is the part which gave way in the specimens before you." But Professor Humphry does not, and could not, mean to imply that *ab*duction is an unusual or an unnatural position; or that during *ab*duction the head of the bone is *not* pressed against the same thin part of the capsule, or that this is *not* the part of the capsule which gives way in dislocation by *ab*duction. I have proved both by experiments and by the lesions in accident cases that such are the results of *ab*duction, and these, at any rate, are points capable of being tested on the *dead* body. The degree of *ab*duction requisite to make the head of the femur press against the part of the capsule which gave way in Professor Humphry's cases is not great; *in every position* of abduction the head of the bone projects beyond the lower edge of the socket, and in some it is more than half out of the acetabulum. But the degree of flexion, *ad*duction, and inversion necessary to make the head of the femur press against the same part of the capsule is extreme, and the attitude resulting therefrom is neither a habitual nor a natural one, with most persons.

I could refer to several instances of traumatic dorsal and ischiatic dislocations which occurred during *ab*duction; two[2] will suffice here. Guersant well describes a case of ordinary dorsal dislocation, and states that the thigh was dislocated by a forcible movement of *abduction and inward rotation*. Crawford reported a case of double dislocation in a miner aged thirty-six, who was standing on an incline "*with his feet widely separated*, the right one being much lower (and therefore much less flexed) than the left, and the body bent forwards. *While in this position* a large mass of rock fell upon his dorsal region, bending his body upon the thighs and pressing him forcibly down upon the rock on which he was standing." The man was certain that both joints were dislocated at the same instant; the right was a dorsal, the left an ischiatic dislocation. Such cases as these cannot be put aside as inconclusive or insufficient. Such a position as this miner was in is one of the most natural and frequent; the forms of dislocation were theoretically and practically perfect.

As to Professor Humphry's third conclusion, I confess my inability to understand it; for I do not know how a dislocation can be other than *indirect* if the head of the bone is "*carried up to a variable extent*," no matter by what force, *after it has left the acetabulum*.

It is, however, a great gain to find a teacher so eminent as Professor Humphry pointing out that in the backward dislocations of the hip the rent is in the *lower* and back part of the capsule; and granting that dislocation is easily caused, in the dead body, by forcible *ab*duction of the limb. But I regret to see he is of opinion "that the view formerly entertained is correct—namely, that the backward dislocations of the hip, whether accompanied by fracture of the edge of the acetabulum or not, are commonly direct, and produced by force applied to the limb in its flexed, adducted, and inverted position." It was this view which led to attempts at reduction by pulleys. It was this view which kept alive the idea that the head of the bone, having passed *directly* back to its abnormal position, must be pulled right again by traction in the axis of the displaced limb. It was this view which sanctioned the barbarous practice of bleeding, tartar emetic, and enormous traction force of hundreds of pounds' weight, continued over several hours. And it was this view which caused large extravasations of blood, and abscesses, around the joint, and even death itself—results such as Professor Humphry, and not a few surgeons besides, witnessed in the comparatively recent past; results which were the outcome of the ignorance of, or an indifference to, the position of the rent in the capsule in hip dislocations. It is this view which, to my thinking, Professor Humphry himself, in his lecture, takes care to explain ought not to be acted upon; for he describes the *rationale* of reduction by manipulation upon the opposite view—the view, namely, for which I contend.

I have good reasons for knowing that during the last ten years a great deal of the instruction given, in London at least, on dislocations of the hip, has been clearer and simpler than it was before. This better understanding is probably much more due to an accurate knowledge of the position of the rent in the capsule than to the fact that dislocations of the hip occur during *ab*duction.

There is, however, this value in knowing that *ab*duction is the simplest and commonest position which favours dislocation: it explains why the rent in the capsule is always in the thin part and below, and why three of the regular forms of dislocations of the hip are (with the rarest, if any, exceptions) indirect or secondary, and that *some* of the other forms are direct only because the head of the femur *remains below*, opposite the rent through which it was forced. It is always desirable to have a reasonable explanation of the success of our treatment, and, as regards reduction by manipulation, this is only to be found in a knowledge of the position of the rent in the capsule, and of the direction taken by the head of the bone after it leaves the acetabulum. In other words, by knowing that in pubic and in dorsal and sciatic dislocations (when not complicated by fracture at the hip-joint), the head of the bone, having been driven down through the thin lower part of the capsule, ploughs its way up outside the acetabulum, and over the deep muscles, to its new position on the pubes, the dorsum ilii, or the ischium; and that the surgeon has to make it retrace its steps—first, down to the rent in the capsule, and then through this rent into the acetabulum. This is the lesson of practical and surgical importance which is taught us by a complete study of hip dislocations, and this fact we all now act upon, whatever may be our individual views of the position of the limb at the moment of luxation.

AN EXPERIMENT IN HOSPITAL PAY SYSTEM.

BY W. J. COLLINS, M.D., M.S., B.Sc. LOND., F.R.C.S. ENG.,
OPHTHALMIC SURGEON TO THE NORTH-WEST LONDON AND WESTERN OPHTHALMIC HOSPITALS;
AND
A. W. WHEATLY, M.B., S.Sc.C. DURH., M.R.C.S.,
SENIOR ASSISTANT-SURGEON TO THE WESTERN OPHTHALMIC HOSPITAL.

So much has been recently written and spoken concerning the theory of the pay system in hospitals that an appeal to actual experience may be both refreshing and instructive. It would be difficult to find a better example of the changes which ensue upon the adoption of the paying system at a hospital, in the number of new cases, in the attendances of the old, and in the receipts and expenditure, than that [illegible]ch we are about to present.

The Western Ophthalmic Hospital was founded in 1856 and is situated in the Marylebone-road. Until the year 1874 it was free to all comers; since then the pay system has been in vogue. From the reports for the last sixteen years we have abstracted the statistics of in-patients, out-patients, attendances of the latter, together with the donations and subscriptions, the patients' payments, and the expenses, from 1870 to the present time, and have arranged them in the appended table in parallel columns. The years which appear in this table are naturally divisible into two periods, owing to "important changes in the management of the hospital,"[1] which took place on Nov. 16th, 1874. Prior to that period "the hospital was free to all comers. Hundreds of poor persons, many of whom came from distant parishes, availed themselves month after month of the benefits thus offered. The institution soon became known as a place where sufferers could obtain both gratuitous relief and successful treatment, each year showing a large increase in the number of patients—1573 new out-patients in 1870 to 2316 in 1874."[2] The committee justly regarded this result as "a proof of the success of their labours," but owing apparently to a pressing financial difficulty, accentuated for the time by the need of extensive repairs, involving the outlay of £300, the committee gave notice that from the "16th of November, 1874, a payment of sixpence per week would be required from each out-patient, and a proportionate sum from each in-patient."[3] No one, however, was to be turned away for want of money. It was not likely that the hundreds of poor from distant parts, who in past years had become acquainted with the gratuitous advantages of the hospital, would immediately become aware of this fundamental innovation. The committee, failing to make allowance for this, and instituting a comparison between the patients' attendances during three months following the new rule, and the same period in the previous year, "rejoiced to report the thorough success of the experiment. The patients have not only subscribed their weekly sixpences with cheerfulness, but have, contrary to the fears of the committee, attended in increased numbers,"[4] and gave the following figures:—

	1873-4.	1874-5.
Patients' attendances, Nov. 16 to Feb. 13	2662	3073
Cash receipts from patients	Nil	£53 11s. 4d.

The committee, moreover, found herein "reason to look for a yearly addition to their funds of a sum more than equal to the present total of their annual subscription list." Such sanguine expectations were, however, speedily dispelled by actual experience, and in the next report (1875) the committee regretted that "the hope that the attendances of patients would not be reduced by the adoption of the paying system had not been realised."[5] The regret was only too well founded, and the figures show a steady decline in the number of new out-patients from 2316 in 1874 (the year of introduction of pay system) to 1467 in 1881, and of attendances of patients from 13,677 in 1874 to 5746 in 1881, the new patients being reduced by one-third and the attendances by more than a half. Whether the result of the paying system was desirable or not, it was at any rate the very reverse of the expectation of the committee, and the pay system commenced upon the plea of economy was justified, and continued "to preserve the self-respect of the patients,"[6] and in the hope that kindred institutions would follow the example of this "bold experiment."[7]

Unfortunately such reciprocity has not commended itself to other charities to any great extent, and the only result of the compulsory paying system has been to turn away from our doors a large number of patients, who fail to see the force of paying here for that which they can receive gratuitously elsewhere. While fully agreeing with the principle that patients able and willing to pay should be permitted or even requested to do so, we believe that unless the Western Ophthalmic Hospital is to be content with its position as the smallest of the five eye hospitals in London, and to allow its hold on the public to further decline, or at best remain stationary, this fettering regulation of compulsory payments must be reconsidered.

We would point out that, as a mere question of economy, a larger attendance does not imply increased outlay, the cost of the treatment of out-patients being ridiculously small. Thus, in the year 1874 the attendances were 13,677, and the expenses £635 11*s.* 6*d.*; in the year 1884 the attendances were 5186, and the expenses £624 5*s.* 6*d.* Evidently the expenses do not vary with the attendances. Moreover, the paying system reacts upon the receipts after the manner of a self-denying ordinance, for, as pointed out by the committee in their last report, "the very circumstance of a self-supporting element in the administration of this hospital deprives it of a portion of the grants that might be apportioned to it were its doors freely open to all in-comers."[8]

A survey of the appended table will suggest the following general conclusions: 1. The patient's attendances, which had steadily increased under the free system, have greatly declined under the pay system. 2. The in-patients are too small in number to permit much weight to be attached to their fluctuation; but the average for five years of the free system was 64; for eleven years of the pay system, 50. 3. The third column is perhaps the most instructive and valuable as a gauge of hospital success. It shows that the steady increase of new out-patients which the free system fostered received a shock by the introduction of payments, which continued for twelve years, while during the last three the increase of cases of eye disease in an increasing population has made itself felt in our hospital in spite of the depressing influence of the pay system. 4. The conclusion to be drawn from the financial receipts is not favourable to the view that the paying system is supported by the alms-giving public. It would seem that the more a hospital seeks to help itself out of patients' pockets the less is it helped by others; and the desire to assist a partially self-supporting charity does not appeal to the charitable sentiment so much as the benefaction of the indigent. 5. The expenses do not appear to vary with the number either of in- or out-patients, or the attendances of the latter, and were not far different in 1873, when the number of in-patients was 86, out-patients 2004, and attendances 14,417, from what they were

[6] Ibid

in 1882, with 55 in-patients, 1478 out-patients, and 5161 attendances. 6. The patients' payments fluctuate unaccountably and in ratio with no other varying quantity. Thus, in 1881, with 1473 out-patients, the receipts were £114 2*s.* 6*d.*, and in 1882, with 1478, they were £208 13*s.* 3*d.*—a difference which an excess of 25 in-patients in the latter year might possibly partially explain, but for which it is totally inadequate to account.

An effect of the pay system which figures cannot show, but of which the medical staff are painfully aware, is that cases of unusual interest, and operation cases generally, are repelled from our doors to be received with open arms elsewhere. One advantage may indeed be claimed for the paying system by way of reducing the attendances of chronic cases where treatment is of no avail, and perhaps in choking off a class of ailments pretty universally recorded as *nihilitis*. From the point of view of medical and surgical practice, then, the adoption of the compulsory paying system, so long as it is not universal, is undesirable and to be condemned; it is questionable whether voluntary payments might not yield almost as large a sum, and would be at least as well calculated to preserve the self-respect of the poor and increase their respect for the charity.

LITHOLAPAXY IN MALE CHILDREN AND MALE ADULTS.

BY SURGEON-MAJOR D. F. KEEGAN, M.D. DUB.,
RESIDENCY SURGEON, INDORE, CENTRAL INDIA.

(*Continued from page 1124.*)

IF space permitted, I might relate the history of several other interesting cases from the series of litholapaxies detailed in the table (*ante*, p. 1069). I have now, however, I consider, produced sufficient evidence to prove that the calibre of the urethra in male children is as a rule much larger than surgeons have hitherto believed to be the case. Amongst the many objections raised against the advisability of performing litholapaxy in boys, there is really only one which is worth much consideration in practice, and that is the hitherto assumed smallness or narrowness of the urethra. The fact is that the whole question of the feasibility of performing litholapaxy with success in male children hinges on the size or calibre of the urethra in these young patients. Mr. W. J. Walsham was the first, as far as I know, to perform litholapaxy pure and simple, in England, on boys. In bringing forward for discussion at the meeting of the Clinical Society of London held on April 9th last the history of a case in which he had successfully performed litholapaxy on a boy aged ten, he stated that experiments instituted by him confirmed the truth of my experience of the size of the urethra in male children. This experience has been gained in the performance of forty-seven litholapaxies with my own hands in this class of patients, and I do not know how I could have gained it in a more practical way. In the table of litholapaxies (*ante*, p. 1069) there are several cases detailed in which I was able to pass a No. 7 lithotrite into the bladder of boys of only two years old, and there is one case of a boy aged one year and nine months into whose bladder a No. 7 lithotrite was passed. I have met with a case in which I have been able to pass a No. 7 catheter into the bladder of a boy of only eleven months old. This case was as follows. In August, 1885, a mother brought her male child, aged eleven months, to the Indore Hospital, labouring under symptoms of stone. The child was the subject of phimosis, which I considered the cause of these symptoms. Being placed under chloroform preparatory to performing the operation for the cure of phimosis, I considered it advisable to clear up any doubts existing in my mind as regards the cause of the stone symptoms, and passed a No. 7 catheter with ease into the child's bladder. I then attached an aspirator, but could detect no click. The phimosis was cured, and the symptoms of stone soon passed away. But had I found a small stone in this case, I should certainly have crushed it with a No. 6 lithotrite and evacuated the débris through the No. 7 evacuating catheter. I should say that in many cases a No. 6 catheter will readily pass into the bladder of a child of one year old, and with a lithotrite and expe[illegible]ite feasible to dispose of a fair-sized stone in half-an-hour. On the other hand, I have often met with cases of boys of two years of age suffering from stone into whose bladders it was impossible to pass a No. 6 catheter, and in such cases I have of course performed lateral lithotomy. In dealing with cases of stone in young boys, I do not as a rule decide the kind of operation I shall perform until the little patient is placed under chloroform. If I find that the urethra will admit a lithotrite sufficiently powerful to crush the stone to be attacked, I almost invariably perform litholapaxy; and if not I perform lateral lithotomy. I have, however, on one occasion begun the operation of litholapaxy, and after proceeding some way in this operation considered it wiser and safer to extract the stone by lateral lithotomy. But this was in the days when I was not well supplied with small fully fenestrated lithotrites. The case is an interesting one, and, briefly stated, is as follows. K——, a boy aged eight years and a half was admitted into the Indore Hospital on April 28th, 1884, suffering from symptoms of stone for three years and a half. The same day I passed with comparative ease a No. 7 lithotrite into the bladder, and at once seized a stone. After a few crushings I withdrew the lithotrite (which was not fenestrated) from the bladder, and in doing so I experienced considerable difficulty in getting it to pass through the membranous portion of the urethra, as the blades had become clogged with the débris of a soft, clayey stone. This clogging had the effect of increasing the size of the lithotrite from a No. 7 to a No. 8. Fearing that this clogging might occur on a second withdrawal of the lithotrite from the bladder, I determined to cut the boy, and, passing in a No. 5 staff, performed lateral lithotomy, making a very small cut in the prostate, and extracted the broken fragments of stone from the bladder by means of an ordinary dressing forceps. The stone weighed 127 grains, and was composed of mixed phosphates and urates. The boy made an excellent recovery, and left the hospital well on May 11th. Here was a boy, aged eight years and a half, with a far less capacious urethra than I have often found to exist in a child of three or four years old.

At starting, I stated that I advocate litholapaxy in male children principally for two reasons—rapidity of cure and absence of a cutting operation. An analysis of the table appended shows that the average number of days spent in the Indore Hospital by boys after litholapaxy was a little over seven. The surgical records of this hospital in past years show that the average number of days passed by boys in hospital after lateral lithotomy was 17·61, and from what I have been able to learn of the statistics of other hospitals in India, it would appear that boys generally remain nearly twenty days in hospital after lateral lithotomy. Now, an average stay in hospital of but seven days after litholapaxy does not fully represent the advantages gained by the patient in having his stone removed by this method. The table does not show the fact that many of these young patients were practically well the day succeeding the operation, and that they were very often only detained in hospital for the purpose of observation. Indeed, some of them were walking about the wards of the hospital the day succeeding the operation. Any lithotomist who has cut many boys for stone will readily recognise the advantages inherent in a method of surgical procedure wherein so much suffering, annoyance, and personal inconvenience can be safely avoided. Rapidity of cure in itself would not of course be a sufficient reason for performing litholapaxy in boys, unless rapidity of cure were accompanied by successful results. And such results I have obtained. Some surgeons would include Case 53, where death was caused by epistaxis and general anæmia some three weeks after all troublesome urinary symptoms had disappeared, amongst the number of unsuccessful litholapaxies. I do not myself think that this case should appear in this category. But, granting that it should so appear, I have still only lost two cases out of fifty-eight, or something under 3½ per cent., which is a rate of mortality considerably less than that usually following the operation of lateral lithotomy in boys in England. I have not selected my cases, but took them as they came. Some of the boys operated on were in a very weakly state of health, and not a few suffered from chronic malaria with enlargement of the spleen. The operation of litholapaxy in boys cannot of course be free from all risks to life, no matter how skilfully performed; and should extensive organic disease of the kidneys coexist with stone in the bladder, there must of necessity be always a certain percentage of mortality after such an operation. But I maintain that if suitable instru-

ments are skilfully and judiciously employed in performing litholapaxy, this operation will be found to be a much more rapid and a somewhat more successful method of dealing with stones in male children than lateral lithotomy. I advocate litholapaxy in preference to lateral lithotomy in dealing with stone in boys for another and very important reason—viz., the absence of a cutting operation.

The operation of litholapaxy, in the performance of which no important structures are cut or wounded, has much to recommend it, more especially in a country like India. A native of India will not, as a rule, undergo any grave surgical operation for the cure of disease until he has tried all other methods of treatment; and he will be even still more loth to submit his child to the terrors of the surgical knife unless he be fully persuaded that an operation is an unavoidable and absolute necessity. He will procrastinate and put off what he considers the evil day to the last hour. And hence it is that surgeons in India are continually meeting with cases of very large stones in young boys. But when the native of India comes to learn, as he is already slowly beginning to do, that in certain hospitals a stone can be disposed of without a cutting operation, he will then seek surgical aid for his child as soon as stone symptoms manifest themselves. I am strengthened in this belief by the fact that at the Indore Hospital the number of admissions into hospital on account of stone amongst boys has steadily increased since litholapaxy has become an established and a recognised operation at this institution. I am sanguine enough to hope that when the prejudices and opposition which have hitherto existed amongst surgeons in India against the operation of litholapaxy in boys shall have disappeared, and when this method of treating stone in boys shall be more generally adopted than it is at present, we shall then more rarely meet with cases of large stones in young male children. And should this operation become an established and widely recognised method of treating stone in boys, its adoption in this class of patients will mean an avoidance of an amount of pain and misery which can be only fully realised by those who are intimately acquainted with the daily lives of the Indian peasantry, cut off as they often are from frequent communication with large towns or cities where hospitals and dispensaries flourish. A glance at the table shows that many of the boys operated on at the Indore Hospital had suffered for four or five years from stone before they sought surgical relief; and I feel certain that many unfortunate Indian boys, living in villages far removed from skilled surgical aid, drag out a miserable existence for some years, and eventually perish with the stones in their bladders. The method of treating stone in boys by supra-pubic cystotomy is not very likely to find much favour amongst the natives of India, and I think that surgeons in India will be slow to adopt it amongst this class of patients. I do not think that surgeons practising in India very generally share Langenbeck's opinion, that the operation of lateral lithotomy in boys is frequently followed by emasculation. The natives of India have certainly not generally noted this after-consequence of lateral lithotomy; and should they ever come to do so, they will at once abandon this time-honoured operation for litholapaxy, or for even supra-pubic cystotomy, although the latter is a cutting operation. They will do so chiefly on religious grounds, for in no other country in the world is the hope of male offspring so intimately interwoven with religious aspirations and practices as it is amongst the natives of our great dependency. I am not in a position to deny or confirm the truth of Langenbeck's statement, for this question I confess has not as yet engaged my attention. It is extremely difficult in a country like India to follow up the life-histories of boys cut for stone at public hospitals, for in India, as in Europe, we meet with stone in boys nearly always amongst the poorer classes of society, and the "short and simple annals of the poor" are not easily traced. Still, the difficulties of collecting the necessary information to settle this very interesting and important question, so far as it refers to Central India, are not insuperable, and on my return to India I shall endeavour to trace the life-histories of all boys cut for stone in past years at the Indore Hospital. The impossibility of wounding the ejaculatory ducts in performing supra-pubic cystotomy would seem, however, to be the principal advantage it possesses over lateral lithotomy in dealing with cases of stone in male children. It may perhaps be an easier method of removing a stone from the bladder of a very young male child than lateral lithotomy would seem to be for those who do not enjoy many opportunities of cutting for stone in boys. I say it may be an easier method advisedly, for I have my doubts on this point. I am inclined to think that the "high" operation in a fat male child of two years of age might possibly be not so easy of performance as the advocates of supra-pubic cystotomy would have us believe. But it will not prove a more expeditious, and it can hardly prove a more successful, method of dealing with stones in boys than lateral lithotomy is well known to be when performed by an experienced and skilled hand. Freyer's brilliant and unequalled success in cutting 143 boys for stone without a death has conclusively shown what splendid results can be achieved by lateral lithotomy when this operation is skilfully performed. On the other hand, the total number of supra-pubic cystotomies performed on boys in England up to the present date is so very small that it is as yet impossible to draw any safe conclusions as to what its rate of mortality is likely to be, and therefore I think I am warranted in expressing my conviction that surgeons practising in India will be slow to abandon lateral lithotomy for supra-pubic cystotomy when dealing with cases of stone in male children. Before leaving the subject of litholapaxy in boys, I should like to make a few remarks of a practical nature.

The operation of litholapaxy in boys differs from the same operation in the adult male only in the size of the instruments employed. Great gentleness and a light hand are essential to success. The evacuating catheters should be as short as possible, and they should be fitted with stilets; for although some authorities state that a fragment of stone impacted in the eye of the catheter is easily removable by briskly working the aspirator, I have on many occasions found that this manœuvre fails to dislodge a tightly wedged fragment. The employment of a stilet then becomes a necessity. The evacuating catheter should never be withdrawn from the bladder with the aspirator attached to the catheter, because in doing so the operator has no means of knowing whether a small fragment of stone is lodged in the eye of the catheter or not; and should a piece of stone project from the eye of the evacuating catheter, the urethra might be lacerated in the withdrawal of the catheter from the bladder. It is, therefore, a wise plan to always pass the stilet into the catheter before withdrawing the latter from the bladder. All lateral and up-and-down movement of the lithotrite should be avoided as much as possible, so as not to strain the neck of the bladder. It is scarcely necessary to say that no undue force should be employed in passing either a lithotrite or evacuating catheter into the bladder. The meatus of the urethra should be incised only when it is considered necessary to do so. The operation very often lasts a considerable time when a stone of considerable size has to be dealt with; for, since the evacuating catheters employed are comparatively small, the stone must be crushed very fine to come through the eye of the catheter. But the surgeon should be in no hurry to finish the operation, and no particle of débris should, if possible, be left behind in the bladder. The aspirator should be freely employed. I think that the performance of this operation in young male children requires a greater amount of skill and dexterity than the same operation in the adult male. But the difficulties are, after all, not very great, and the surgeon who has performed a few litholapaxies in the adult male with success may then safely proceed to operate by this method in young male children. Whoever wishes to give litholapaxy in boys a fair trial must supply himself with a set of completely fenestrated lithotrites, beginning at No. 6 and running up to No. 10 (English scale). To recapitulate. Use completely fenestrated lithotrites suited to the calibre of the urethra; if possible, crush the stone in the bladder into fine powder, and you will not then require to use large evacuating catheters; never use a lithotrite or an evacuating catheter which will not pass readily in and out of the bladder; be extremely gentle and careful in practising all manipulations in the bladder and urethra; do not be in a hurry to finish the operation; use the aspirator freely, and never, if possible, leave a single grain of débris behind in the bladder. If all these conditions be fulfilled, you may count on a large measure of success. Some cases you will meet with where no lithotrite, however small, can be employed with safety, and these are the cases which should be dealt with by lateral lithotomy.

Having now considered the operation of litholapaxy in its application to the treatment of stone in male children, I should like to touch on some points of present interest connected with its [illegible] the adult male. It would

appear that whilst surgeons in India are endeavouring to widen the sphere of litholapaxy their brethren in Europe, and even in America, seem inclined to restrict Bigelow's operation to very narrow limits. This divergence in opinion and practice between the East and the West has doubtless been brought about by the increasing favour now being accorded to the operation of supra-pubic cystotomy in its revived form. I have had no practical experience of the "high" operation; but, in common with most surgeons, I recognise the fact that in its latest development it is eminently adapted to the treatment of very large stones, which cannot be disposed of by litholapaxy or by perineal lithotomy. And in dealing with cases of tumours of the bladder and encysted stones, no matter what their size may be, it is doubtless the correct method of surgical procedure. It cannot, however, be said that there exists a universal consensus of opinion amongst practical surgeons at the present day as to where we should draw the boundary-line between litholapaxy and supra-pubic cystotomy. I certainly am not disposed to draw this line at a stone which is hard and much above an ounce, and I feel certain that my brethren in India, with their unrivalled opportunities of treating stone, have no intention of adopting a course of practice which I can only characterise as retrograde.

The size, density, and weight of a stone must be carefully considered when drawing the boundary-line. But the size, density, and weight of a stone are not the only important points of the problem to be solved. The size and the general condition of the bladder and prostate, together with the size or calibre of the urethra, are equally important points for consideration before we can arrive at any safe conclusion as to the method of treatment best adapted to each individual case. Indeed, no operator can tell with anything approaching accuracy the weight of a stone in the bladder when grasped between the blades of a lithotrite. The weight can only be determined after its evacuation from the bladder, and its density can only be learned during the progress of the operation. And, therefore, rules laid down to guide inexperienced surgeons in drawing the boundary-line between litholapaxy and supra-pubic cystotomy based solely on the weight and hardness of a stone must prove valueless and misguiding in actual practice. For it often happens that a stone of moderate size lying in an irritable, contracted, and diseased bladder will give the operator much more trouble than a stone weighing upwards of three ounces will do, in a roomy and healthy viscus. Again, there are some cases, happily rare, wherein the bladder continues to contract during the whole course of the operation, grasping with spasmodic effort the lithotrite, impeding its working and ejecting the water thrown in by the aspirator. These are certainly the most difficult cases we meet with in practice, and should the novice in performing litholapaxy be so unfortunate as to come across a case of this kind, it will give him an exaggerated idea of the difficulties to be met with in performing litholapaxy in the ordinary run of cases. It requires all the patience, care, and skill which an experienced hand can command to combat such conditions as these. Indeed, it is a question for consideration whether even an experienced litholapaxist would not better consult the safety and welfare of his patient by having recourse to perineal or supra-pubic lithotomy when brought face to face with a case of this kind, more especially if the stone happens to be at all large. I am, however, of opinion that any uncomplicated stone on which the surgeon can lock a trusty and efficient lithotrite can in most cases be crushed and evacuated from the bladder at one sitting. By an uncomplicated stone I mean one not complicated by an enlarged and diseased prostate, and which lies free in a healthy and roomy bladder. I can, of course, imagine a case in which the surgeon, having locked his lithotrite on a very hard mulberry calculus, weighing between two and a half and four ounces, would fail to break it; and I can also imagine a case in which the surgeon, having broken across a large stone, would still be unable to evacuate it at one sitting owing to the inability or unfitness of the patient to remain sufficiently long under an anæsthetic to permit of the operation being completed at one sitting. But putting aside exceptional cases such as these, I think that, using efficient modern instruments, the surgeon ought to be able to dispose of any uncomplicated stone on which his lithotrite will lock, at one sitting. I would go even further, and say that some stones on which a lithotrite will not in the first instance lock can be reduced in size to the working capabilities of the lithotrite by judicious chipping of the outer covering of the stone, and that then the operation can be completed at one sitting. In dealing with cases of large, soft, phosphatic stones this chipping process is quite feasible. I shall now endeavour to substantiate these views by relating the histories of some cases from my own practice at the Indore Hospital.

M. S——, forty-nine years of age, suffering from stone symptoms, was admitted into the Indore Hospital on Dec. 16th, 1884. He suffered from emphysema of the lungs; his heart was weak, and he was very corpulent. His muscular system was very flabby. Urine acid; specific gravity 1014; no albumen. On Dec. 17th he was placed under chloroform, which he took very badly. Equal parts of chloroform and ether were then tried. The largest lithotrite which could be used with safety was a No. 12 fenestrated. The stone was readily seized, but the inspiratory and expiratory efforts were so deep and laboured that the water injected into the bladder was soon expelled, and so the bladder kept continually contracting on the lithotrite, rendering the operation most difficult and tedious. A No. 14 evacuating catheter (English scale) was the largest I was able to employ. The lithotrite was introduced sixteen times, and the operation lasted two hours and thirty-five minutes, although the stone, mixed lithic acid and phosphates, only weighed 272 grains. This will give some idea of the difficulties attending the operation of litholapaxy in this case. Again and again I was obliged to cease working the lithotrite and aspirator in the course of the operation, owing to the frequent spasmodic contractions of the bladder. I have frequently removed stones weighing between two and three ounces with far less difficulty than I experienced in this case.—Dec. 19th: Pulse 120; evening temperature 104°; suffering from an attack of asthma; right testicle swollen; some pain on pressure over bladder.—22nd: Feels burning at time of micturition; condition of testicle unchanged; sounded bladder with Sir H. Thompson's sound, but no fragment of stone could be detected.—26th: Does not sleep well; pain in epigastric region; getting weaker; has difficulty in breathing; had two fits of asthma.—27th: Dyspnœa increasing; pulse rapid and weak; becoming drowsy. Died during the night. No post-mortem examination was obtainable.

I ascribe the fatal issue in the foregoing case to the lengthened administration of chloroform and ether in a patient suffering from emphysema of lungs and weak heart. If I were again to meet with a similar case, I should most certainly perform either perineal lithotomy or supra-pubic cystotomy in preference to litholapaxy, for I consider that litholapaxy is contra-indicated in cases where a contracting bladder keeps on continually grasping the lithotrite and expelling the water injected by the aspirator. We have performed ninty-three litholapaxies in boys, men, and females at the Indore Hospital between May, 1884, and the end of March, 1886, and this case is the only one amongst this large number of litholapaxies which has proved fatal. Indeed, I am disposed to think that, had I used no anæsthetic, and had performed lithotrity instead of litholapaxy in dealing with this stone, the result might have been different from what it was. The history of this case goes to prove how valueless in actual practice are the rules which have been laid down to guide us in drawing the boundary line between litholapaxy and supra-pubic cystotomy, rules which are based solely on the weight and density of a stone.

(To be concluded.)

ON HYSTERICAL AFFECTIONS.

BY F. T. THISTLE, L.R.C.P. LOND. &c.,
SURGEON TO THE TORBAY HOSPITAL, TORQUAY.

IN THE LANCET of Sept. 18th is an interesting report by Dr. Suckling of a case of what he terms "paralysis depending on idea." Whether the difference between the cases denominated by this somewhat cumbersome phrase and those of so-called hysteria is fanciful or not need not concern us much at present. Dr. Suckling thinks that there is a difference in the character of the patient, and perhaps he is right. That such cases are "hysterical" in the literal sense of the word no one for a moment supposes. That much-slandered organ, the uterus, has quite sufficient responsibility in carrying out its normal functions without

being saddled with all the ills which we are unable to localise in any of the other organs of the body. The term "hysterical," however, as applied to these cases, is a convenient one, and will probably continue to be used. There is no class of cases which yield such satisfactory results when judiciously treated as these hysterical affections. On the other hand, if not properly managed, there is no class so difficult to benefit in any way. We hear a good deal of the *vis medicatrix naturæ*, and no doubt physicians gain a good deal of credit which really belongs to nature; but in the cases now under consideration nature is a most hopeless failure, and the physician achieves his greatest triumphs. With regard to the difference in disposition alluded to by Dr. Suckling in patients of this class, some being cheerful, intelligent, and anxious to recover, others just the reverse, the same difference is equally noticeable in patients suffering from other diseases. One thing, however, should not be forgotten, which seems to me to have a decided influence on this point, and that is the length of time the affection has existed. If it has been in progress for months or years, the patient has naturally become depressed and given up all hope of recovery; perhaps she has been under the care of many medical men, and owing to unfavourable circumstances has received no decided benefit. With regard to treatment, if possible it is always better to remove the patient away from her friends, whose injudicious sympathy tends to counteract all beneficial remedies. My own experience is that these cases do better in a hospital than anywhere else, where you have a reliable nurse, who will take an interest in the patient and carry out all your directions. They require so much time and attention that it is almost impossible for a busy practitioner to carry out the treatment effectually. The next step is to gain the confidence of the patient, and not only to impress on her that she will get well, but also to prevail on her to use her utmost efforts in this direction, and to encourage her when we really see that she is making such efforts. The following three cases will serve to illustrate some of the curious phases of this very interesting affection. They came under my notice at the Torbay Hospital. I will state them as briefly as possible.

CASE 1.—Harriett B——, aged forty, unmarried, dressmaker, was admitted into the hospital on Feb. 22nd, 1883. She had always been a very emotional subject. Three years before admission the left breast was removed at the Middlesex Hospital for scirrhus. She had been in bed eleven weeks before admission. She complained of pain in the left thigh and leg; there was no swelling; the muscles were slightly wasted; the left lower limb was completely paralysed, and she could not move it in the bed; there was partial anæsthesia of the whole limb, most marked on the inner side of the thigh; she was anæmic in appearance. She was put on strychnine and iron; the leg was faradised daily, and blistered in a few places with the thermal hammer. In three days she was walking on crutches, a few days later with a stick only, and soon was able to walk without any support at all. She had some difficulty at first in getting up and down stairs, but was made to practise it several times in the day. She gradually improved in health and strength, and was discharged on May 21st, when she could walk several miles a day.

CASE 2.—Mary W——, aged twenty-five, formerly a servant, was first seen by me in consultation with Dr. Wills about the middle of February of last year. She had been in bed for five years, and had to be lifted from one bed to another. She was a most pitiable object, emaciated, peevish, unable to stand or walk or feed herself. She could move her legs in bed, but in getting her out of it they gave way under her, and she would have fallen if not supported. I offered to take her into the hospital, telling her that she would get perfectly well. She objected very much, and said she did not want to get well. After much persuasion she consented to come in, and was admitted on Feb. 24th. On admission I ordered her milk and beef-tea at first, as she had taken nothing but slops for some time. She was faradised and rubbed every day. On the third day I ordered her a mutton chop; this she obstinately refused to eat, saying she could not swallow it. On being informed of this by the nurse, I went up into the ward, cut the chop into small pieces, and insisted on her eating it, threatening to apply the battery if she would not do so. After a good deal of trouble she ate the whole of it, with some bread and a cup of milk. After this we had no further trouble about her food and she was put on a liberal diet. On the fifth day she was out of bed, and able to walk a little when supported on each side by a nurse; a few days later she could walk with crutches in the garden. She gradually gained flesh and strength, and was discharged from the hospital seven weeks from the date of admission, able to walk two or three miles in the day. She then went for a few weeks to a convalescent home in the country, and returned much benefited by the change.

CASE 3.—Mary T——, aged twenty-one. I first saw this patient with Dr. Eales on July 11th of the present year. She had been in bed or on a couch for three years, and was considered by her friends to be suffering from heart disease and consumption. She was very emaciated, and could not stand without being supported; her breathing was rapid and noisy, and she jerked out her words in a spasmodic manner when answering questions, which she rather whispered than spoke. She complained of pain over the region of the heart, which was beating quickly and feebly: the sounds were natural; breathing jerky, but nothing abnormal about the lungs. We recommended her friends to send her into the hospital, and promised that she would get quite well. She was admitted under my care on July 13th. Her weight on admission was 67 lb. She was faradised and rubbed every day, given as much good nourishing food as she could be made to eat, and ordered cod-liver oil and iron. As in the previous case, she was got out of bed, and walked at first with support, and very soon by herself. A small blister was placed over the region of the heart, which removed the pain she complained of. The breathing soon became natural. She rapidly gained flesh, strength, and weight. In a fortnight she was able to take good walks. She was discharged on September 16th, and sent to a convalescent home on the Moor. Her weight on leaving was 80 lb., having gained 13 lb. in rather more than two months.

The above cases are examples of many to be met with in practice. Whatever name we may apply to them—real, ideal, hysterical, or neurotic,—they are all of them very amenable to treatment, are extremely interesting to watch, and amply repay in their satisfactory termination the time and trouble devoted to them.

Torquay.

CASE OF

IMPERFORATE HYMEN WITH RETENTION OF MENSTRUAL FLUID.

BY HENRY DAVY, M.D. LOND., M.R.C.P.,
PHYSICIAN TO DEVON AND EXETER HOSPITAL.

MARY F——, aged fourteen, was admitted under my care on April 24th, 1883. In the previous October she began to suffer from pains in the back and thighs, which caused her to stay in bed for one week; after this she got better, but for two or three months past the pains have increased in severity. She never noticed any periodical recurrence of these pains, and her mother attributed them to rheumatism. She had never menstruated. She is a well-developed, healthy-looking girl. I first saw her on the morning of April 24th, but having an appointment in the country, and her case being apparently of no urgency, I did not pay much attention to her symptoms. At 9 P.M. the same evening I was asked to see her. She had been suffering from some amount of pain in the back and thighs all day, but not more than she had previously done. About 8 P.M. she called the nurse's attention to a swelling between her legs, on seeing which the house-surgeon sent for me. On examination I found that the external genitals on the left side were much swollen, blood having extravasated into both the labia majora and minora on that side. So much was this the case that the left side of the labia majora was much thickened, whilst the lower part of the corresponding labia minora was so much altered that it was evidently about to slough. Between these swollen parts on the left and the corresponding parts on the right was a small, bulging, soft, and fluctuating swelling, evidently caused by blood pressing an imperforate hymen forward. The hymen was thick and tough, but in one spot it had partially ruptured, and a small piece of clot protruded through the small aperture where the rupture had occurred. A careful examination proved that the vagina was much distended. The labia majora and minora on the right side appeared perfectly natural, while no

tumour could be made out above the pubes. The case did not seem to me to warrant any delay in treatment. I had to do with a much-distended vagina, and the hymen was already ruptured. It seemed probable, also, both from palpation of the distended vagina externally, and from the fact that clot had protruded through the ruptured hymen, that the vagina was distended with clot. It seemed, therefore, useless to attempt to empty the vagina with an aspirator, and I therefore determined to adopt a bolder line of treatment. By the help of a probe and my fingers I completely ruptured the hymen and turned out of the vagina just 18 oz. of blood, mostly firm clot. This clot was particularly firm, retaining in great measure a cylindrical form after evacuation; it almost appeared to be undergoing organisation, and was evidently formed from almost pure blood, without admixture of secretion from the uterus and vagina. Behind the clot was a small quantity of thick dark treacly fluid, probably ordinary blood mixed with the vaginal secretions. Passing two fingers as far as possible into the vagina, I found the latter very greatly distended; none of the usual parts could be made out, and no part of the uterus could be reached. I now passed the nozzle of a Higginson syringe along my fingers, and very slowly washed out the vagina with a solution of carbolic acid in water, in the proportion of 1 in 80. I continued the injection carefully until the lotion returned unaltered, taking care that it had a very free escape along my fingers, and that the syringing was very slowly performed. After this an opium pill (a quarter of a grain) was given every six hours.

April 25th.—The patient has passed a quiet night, and there is no pain or tenderness over the abdomen. The vagina contains a considerable amount of yellowish discharge, which has a very offensive smell. I syringed all this away as before.

From this time the patient did well, and made a good recovery, without pain or fever. The yellow offensive discharge continued for some days, but the parts were carefully washed with the carbolic lotion twice a day. The left side of the labia majora recovered its usual appearance; the lower half of the left labia minora sloughed away, but the wound healed without any trouble. The patient was kept in bed for five weeks, but menstruation not appearing, and she being apparently well, she was allowed to get up, and after four more weeks to leave the hospital. Up to the time of her leaving I could never reach the os uteri with my finger, although the parts seemed otherwise normal. Up to July 6th she had not menstruated, but since then I have lost sight of her.

Many cases more or less similar to the above are on record, and there is nothing particularly original in the treatment adopted. In Dr. Galabin's little work on Diseases of Women, p. 41, he says: "When the collection of fluid is comparatively small, a free opening may be made at once. Experience has not yet fully decided whether it is better or not to wash out the cavity immediately. It appears preferable, however, as in the former case, to wait twelve or twenty-four hours for gradual evacuation before injecting, unless any sign of decomposition or febrile symptoms have previously appeared." I have put this case on record as shewing the benefit of immediately washing out the cavity as recommended by Dr. Emmett and others. Even after this was done the vagina, as the report shows, contained a considerable amount of yellowish discharge with a very offensive smell within twelve hours after evacuation; and I attribute much of the success of the case to the care and frequency with which this was washed away. At the same time, I think very much care should be taken, as in this case, to have one's fingers in the vagina as far as the nozzle of the syringe, and to syringe most slowly, taking care that there is a very easy escape from the vagina of the lotion injected.

BRITISH PHARMACEUTICAL CONFERENCE FORMULARY.—A meeting of the committee was held at 17, Bloomsbury-square, on Dec. 8th, at 6 P.M. At 9.30 there was an adjournment until 10 the following morning. Present: Mr. Martindale (in the chair), Messrs. Abraham, Greenish, Groves, Martin, Reynolds, Thresh, and W. Naylor (secretary). Letters regretting inability to attend were received from Messrs. Maben and Symes. Lists of suggested preparations and formulæ were discussed, and agreed to be reported upon.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

OXYGEN IN THERAPEUTICS.

BY CHARLES J. SMITH, M.R.C.S., F.R.G.S., &c.
FORMERLY SURGEON TO THE FARRINGDON DISPENSARY, E.C.

ENGLISH medical literature is singularly deficient in works upon the value of oxygen as an addition to our therapeutic agents—and for this reason, that from one cause or another, but chiefly from the difficulty and cost of production of the gas in any quantity, oxygen has never been brought into general use by the profession in this country, so that no large experience of its advantages has been gained; while, unfortunately, those persons who have written at all upon the subject have done so in such a manner as to have exposed it to the suspicion of quackery. This is greatly to be deplored, because there can be no question that the gas, which Lavoisier characterised as "the vivifying spirit *par excellence*," is an agent of the highest value to the physician.

Those who are desirous of learning what has been done with oxygen must look to the papers read before the various scientific societies on the Continent, and to the records of the practice of many distinguished continental physicians. Demarquay appears to have been a somewhat enthusiastic believer in the efficacy of oxygen inhalation: and he has written strongly upon the subject in his work on "Pneumo-therapeutics." He considers this as one of the safest agents in the treatment of pulmonary phthisis in every stage of the disease, and that its curative action is still more manifest in bronchitis, asthma (spasmodic no doubt is meant), and whooping-cough. Hayem, as well as Demarquay, reports favourably of its use in anæmia and scrofula. Durand-Fardel, Béranger-Feraud, and Thierry-Mieg have utilised its combustible action in the treatment of diabetes, in which disease its use is highly extolled by Dr. E. Morin, who, in his prize essay, read before the Society of Medicine in Antwerp, states: "In inhaling from ten to twenty litres of oxygen every morning the sufferer from diabetes will add to his treatment an incontestably useful agent, especially if his lungs have any tendency to become congested." Dr. Campardon read a paper before the Society of Practical Medicine in Paris. Mayer, Maunoir, Pinard, and Dorean have published among them the details of eight cases, of which the last three were cases of incessant vomiting. Quinquod and Kirnberger have also contributed to the records of success which has attended the administration of oxygen. The most recent, and perhaps the most interesting, use made of this agent was during the late terrible epidemic of cholera at Toulon and Marseilles, when highly favourable results were obtained and are duly recorded in the official reports of the Chief Medical Officer of the Marine. There is every reason to believe that the surgeon too may find a faithful aid in oxygen. Langier appears to have met with considerable success in the treatment of senile gangrene and "local asphyxia congestion" by oxygenated baths. There are many others who have published the results of their experience with oxygen; but those already quoted will be sufficient to show how well worth attention it is as a therapeutic agent.

The two great difficulties which have opposed the use of oxygen on the very threshold have been the cost of its production and its impurity when produced. These difficulties, however, have been successfully overcome by MM. Brin, members of the Société d'Hygiène Français, who have succeeded (after the devotion of fifteen years of their lives to the subject) in perfecting a process by which oxygen is obtained in an absolutely pure state from atmospheric air, and this at a cost which places it as much within reach as the ordinary medicinal agents in daily use. This process of obtaining oxygen is really a most simple one. Although Boussingault stated in a report made to the French Academy of Science thirty years ago that oxide of barium was an unstable agent for the purpose, yet it is this selfsame agent that MM. Brin have succeeded in making their servant. Their anhydrous oxide of barium, placed in retorts heated to a given temperature, and served

with a supply of purified atmospheric air, will give off every two hours oxygen at the rate of one cubic foot per pound of barium oxide. Perhaps the most interesting point in connexion with this process is that it is absolutely a mechanical one. There is no loss or waste of the agent employed—namely, the anhydrous oxide of barium. There is no visible difference under the microscope between the low and the peroxide, and no chemical change takes place. The oxygen is absorbed from the purified air passed through the retorts under pressure; it is given off again under vacuum; and the proof that in carrying out this method MM. Brin call to their aid no complex chemical decomposition is, that the same pound of barium, increased in weight when it takes up the oxygen, returns to its exact original weight when, under vacuum, the oxygen is yielded up. Moreover this same pound of barium is at once ready to perform, and repeat *ad infinitum*, its task of absorbing and yielding up this perfectly pure oxygen.

Park-street, W.

CASE OF MENSTRUATION AFTER REMOVAL OF PREGNANT UTERUS AND APPENDAGES.

By LAWSON TAIT, F.R.C.S.

E. P——, aged thirty-three, menstruates somewhat profusely at irregular times, and has done so twice in the last three weeks. This has continued since I removed the uterus (at the fourth month of pregnancy) in August, 1884. A large soft sarcoma grew from the fundus, and the whole uterus was infiltrated with nodules of the same growth; therefore the clamp was made to include as much of the organ as could be pulled up, and I believe the whole of the organ was removed. Previous to the operation, she tells me that she never had any sexual enjoyment, but that now she has it occasionally. The vagina is now (Nov. 22nd, 1886) greatly elongated, and a small pimple can be felt at the upper end of it, in the cicatrix.

Birmingham.

LARGE ILÆMATOMA OF BUTTOCK; ASPIRATION.

By J. HEADLEY NEALE, M.B.ED., M.R.C.P. LOND.,
ASSISTANT-PHYSICIAN TO THE LEICESTER INFIRMARY.

ON the evening of Sept. 3rd, 1885, I was sent for to see Mrs. M——, the wife of a travelling photographer, who was stated to be suffering from persistent loss of sleep, following an injury. I found the patient, a stout comely-looking woman of fifty years of age, bathed in a profuse perspiration, and exhibiting signs of extreme mental as well as physical prostration. She complained of a dull aching pain in the region of the left buttock, which deprived her of any but the merest snatches of sleep, and gave me the following history:—One evening, about three weeks previously, she was leaning against the gate-post at the entrance of the yard in which her husband's photographic "saloon" stood, talking with a neighbour, when a two-horse waggon turned into the gateway. The horses shied, and, instead of making the curve, the waggon came over the corner of the pavement, and my patient was jammed between the near fore-wheel and the gate-post, from which perilous position she was rescued by the prompt action of her friend, who dragged her clear of the wheel. Since the accident she had been under the care of an unqualified practitioner. The application of some "oils" had raised a huge superficial sore—fortunately, however, *not* over the most prominent seat of injury, but doubtless adding in a great measure to the condition of prostration from pain and insomnia in which I found the patient. Careful inquiry elicited the fact that the bladder and rectal functions were normal, so I prescribed a draught containing bromide of potassium and chloral hydrate, promising to make a more systematic examination of the swelling on the following day.

This I did, and, on the principle of exclusion, made up my mind that I had to deal with one of three things—(*a*) malignant tumour,[1] (*b*) gluteal abscess, or (*c*) hæmatoma (unabsorbed). The size and period of growth negatived the first, in addition to which I thought I could detect obscure fluctuation. A subnormal temperature contra-indicated the second alternative, so I made the diagnosis that there had been fracture of the gluteal muscles with deep-seated hæmorrhage. An exploratory puncture with a fine trocar and cannula, placed the matter beyond a doubt, several drops of serous fluid with flakes of fibrin oozing through the cannula. On Sept. 7th, after cleansing the parts with a 1 in 2000 solution of corrosive sublimate (the discharge from the sore referred to smelling badly), I plunged a hollow needle attached to a Potain's aspirator into the most dependent part of the swelling, and drew off a quantity of blood-stained serum (17¾ oz., carefully measured) with flakes of fibrin in suspension. There was so little apparent diminution in the size of the tumour, that I felt convinced that all the fluid had not been evacuated, and reluctantly withdrew the needle, only to find it, as I had anticipated, plugged with fibrin. The patient expressed herself as much relieved, but in the course of a few days, the dull aching pain having returned, I aspirated a second time, using on this occasion a good-sized trocar and cannula, and removing 14½ oz. of fluid. Rapid resolution followed, and then the condition of the injured parts was plainly shown. Running downwards and inwards from the back of the great trochanter was a nodulated ridge, the contracted tendinous fibres of the gluteus maximus, which had been torn through close to its insertion, while the belly of the muscle hung as a flabby useless mass, giving an asymmetrical appearance to the buttocks. The patient made a rapid and complete recovery, with the exception that on flexing the trunk beyond a certain angle (as on stooping to pick up anything from the floor) she was unable to regain the erect posture without the aid of extraneous objects, such as a chair or table leg; and failing these she adopted much the same tactics seen in children suffering from pseudo-hypertrophic paralysis, by climbing up her own thighs.

I saw Mrs. M—— in July last, ten months after the accident, and found her in good health, but complaining that "the place ached a good deal in wet weather." Her daughter informed me that they sometimes had to help her up when she stooped, and if more fatigued than usual she could not get upstairs to bed without assistance. The patient allowed me to inspect the parts, and I found that the asymmetry persisted in a marked degree, a deep furrow indicating the line of fracture of the muscle.

Leicester.

[1] I have twice seen a sarcoma result from a hæmatoma following an injury, and have long regarded this as one of the "ultimate destinies" of blood-clot.

A CASE ILLUSTRATING THE NEED OF CAUTION IN THE USE OF SALICYLIC ACID.

By W. T. FREEMAN, L.R.C.P. Lond., M.R.C.S.,

IN connexion with the annotation in THE LANCET of Oct. 2nd on salicylic acid ("salicylated beer") the following notes should prove interesting.

A short time ago I was attending an old lady of fifty-nine years of age. My attendance to the time of her death extended over a period of three weeks, but she had been attended for a few weeks previously elsewhere by another medical man. Her symptoms ran as follows: A great feeling of malaise, of depression of spirits, with always more or less of a slight headache; tongue coated with brownish fur, especially at the back; sallow skin; stools clay-coloured; bowels opened freely every day; pulse during the whole of the three weeks full, and beating at the rate of from 105 to 110 per minute; never any rise of temperature; specific gravity of urine about 1020, acid, with distinct trace of phosphates, but no albumen or sugar. She was restless at times at night, even to the extent of getting out of bed aimlessly. I diagnosed the case as an obscure one, but expressed my opinion that she was suffering from congestion of the liver, and probably also from some congestion of the brain. The patient was generally of a feeble habit. On the twentieth day of my attendance, although she showed no alarming symptoms whatever, and as she became but slowly better, I suggested a consultation. She had improved, however, in these respects—the motions had become of an almost natural colour, and the headache was better; the rest of the symptoms were unchanged. The treatment to that day had been attending to the bowels, regulating diet, and keeping the patient quiet, whilst medicinally she had been taking a simple effervescing

mixture of tartaric acid and bicarbonate of potash, with ten grains of bromide of potash in each dose, three or four times in the twenty-four hours. After most carefully considering the case, the gentleman I had called in came to the conclusion that a rheumatic taint was at the bottom of the remaining mischief, and prescribed for her fifteen grains of salicylic acid, together with small doses of carbonate of soda, carbonate of ammonia, and tincture of nux vomica three times daily. In this treatment I coincided. She was quite in a natural mood in the afternoon that we saw her together, and we were agreed that there was no cause for alarm, and that there was reasonable hope of her being restored to her usual state of health in the course of a few weeks. I saw her no more till next morning; she had then taken three doses of the salicylic acid mixture. I found her comatose and rapidly sinking. The urine contained albumen. We had another consultation as soon as possible, but she died in the course of a few hours. Although probably the brain symptoms were more severe all along than I expected, and most likely the head mischief would have ended her days, yet I cannot help feeling that our last attempts to cure our patient only resulted in the abrupt snapping of the thin cord of life she had left to her.

Pangbourne.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. THOMAS'S HOSPITAL.

POISONING BY CYANIDE OF POTASSIUM; RECOVERY; REMARKS.

(Under the care of Dr. ORD.)

THE following case is one presenting some points of great interest: the large amount of the poison taken, the severity of the effect produced, and the recovery from this condition, considering the duration of time which had elapsed between the taking of the dose and the commencement of treatment. Cyanide of potassium produces symptoms similar to those which follow the administration of prussic acid, and produces its poisonous effect with nearly the same rapidity. For the notes of the case we are indebted to Mr. A. A. Brockatt, late house-physician.

Sophia P——, aged thirty, was admitted at 4 P.M. on Oct. 4th, having taken cyanide of potassium with an intent to commit suicide about fifteen minutes previously. She appears to have been living a very unhappy domestic life, and took a piece of the salt, "the size of an ordinary lump of sugar," and chewed it, swallowing the greater amount, a stock being kept in the house for business purposes. In a few seconds she became very giddy, and her head swam; but she remembered nothing more until she found herself in bed at the hospital. According to a statement made, she fell suddenly on her face without uttering a sound; the assistance of the police was then procured and she was brought direct to St. Thomas's. One of the policemen removed several pieces of the salt from between her lips while in the house.

When seen at the hospital, about ten minutes later, she was completely insensible, and, except for an occasional gasping inspiration, was in a state of apnœa. Her face was flushed and of a livid hue, the limbs flaccid and cold, the pupils dilated, and the eyelids closed; the pulse was imperceptible at the wrist, and the jaws were tightly clenched. She had passed urine unconsciously, but not fæces. An odour of bitter almonds pervaded the whole room. The patient was supposed to be dead when brought into the hospital.

Artificial respiration was at once resorted to, with cold affusions and flagellation of the chest with a wet towel. The mouth having with great difficulty been opened with a screw gag, the contents of the stomach, which had the same characteristic smell, were pumped out, and about fifteen ounces of a solution of ferrous sulphate (twenty grains to the ounce) injected. The stomach was not full. While this was being done the breathing entirely ceased, and artificial respiration had to be hurriedly resumed. An injection of forty minims of ether was administered, and her condition gradually improved, but artificial respiration had to be kept up more or less continuously for one hour, and for shorter intervals during another, as her breathing stopped whenever it was left off. Even at the end of this time the respiratory acts were extremely shallow and irregular, but they improved markedly after another ether injection. Previously to this a quantity of solution of carbonate of potash had been poured down her throat.

The patient gradually began to recover consciousness in about two hours after admission, but appeared to be in a very dazed condition, was extremely sleepy, and could give no account of herself. She recovered, however, during the evening, and complained of nothing but extreme drowsiness and an uneasy sensation of heat behind the sternum and in the epigastrium. Before recovering consciousness she was very sick, and continued so at intervals for a few hours; the first vomit gave a decided prussian blue tinge with sulphuric acid, and was of a dirty-green colour. Her breath smelt faintly of bitter almonds during the next day, and she slept almost continuously, but she had no further symptoms, and left the hospital in four days quite well. She admitted having been drinking during the day, but was not intoxicated.

Remarks by Mr. BROCKATT.—The above is one of the few recorded cases of recovery from poisoning by cyanide of potassium. The dose in this case was a very large one. Several cases have been recorded which have proved fatal after five grains, but it was here estimated that she must have had at least forty grains. The great symptom was the persisting interference with respiration, and I have no doubt that perseverance with artificial respiration, combined with the subcutaneous injection of ether, was the great factor in saving the patient's life. It seems unlikely that antidotes could have had much influence in the happy result attained, as fifteen minutes had elapsed before they were administered.

LINCOLN COUNTY HOSPITAL.

THREE CASES OF OVARIAN TUMOUR; OVARIOTOMY; RECOVERY; REMARKS.

(Under the care of Mr. T. M. WILKINSON.)

FOR the following notes we are indebted to Mr. M. Johnston, house-surgeon.

CASE 1. *Multilocular Cystic Disease of the Left Ovary: Small Cyst of Right Ovary.*—E. K——, aged fifty-four, was admitted on Feb. 15th, 1886, having been sent by Dr. Lett of Redbourne. Married; has had five children, one (the last aged twenty-one) still living; the others died of consumption. Had always been healthy. She first noticed pain with swelling in the left iliac region about eight months ago, which had increased rapidly in size since that time. Menstruation had ceased for about twelve months, with one exception about midway during that interval, when it lasted seven days, and whilst in the hospital a discharge came on lasting three days. Her appearance is healthy although thin and emaciated. Heart and lungs normal. Abdomen distended by a tumour, which is dull on percussion for three inches above the umbilicus, resonant in left flank, but dull in the right; the tumour appears movable, and composed chiefly of solid matter. There is a great deal of fluid in the peritoneal cavity superficial to the tumour. Abdomen measures 42 in. around the umbilicus. Uterus high up, normal, and free from tumour.

Ovariotomy was performed on March 9th. Chloroform was first administered, but, causing asphyxia, the A.C.E. mixture was given, and answered well. On opening the abdomen there was a rush of peritoneal fluid. The tumour was a multilocular cyst, with a large amount of solid and semi-solid gelatinous material, which weighed 7¼ lb.; the amount of fluid, cystic and peritoneal, was five gallons. There were some slight adhesions to the omentum. The original incision had to be considerably enlarged to admit of the removal of the tumour. The pedicle was tied with silk, cut short, and returned. On examining the right ovary, it was found diseased, a single cyst, about the size of a small orange, being removed with the ovary. The abdominal cavity was sponged out, and the edges brought together with deep carbolised gut and superficial silk sutures, a glass drainage-tube being left at the lower part of the wound. The dressing was dry

antiseptic gauze. While being lifted into bed the patient became collapsed; the drainage-tube was found to be filled with blood. This was removed from the tube, and as there was no recurrence the cavity was not opened again. Serum tinged with blood continued to pass through the tube for some days. When the tube was removed the wound kept open by it healed in a few days. The bleeding was caused by the tube being caught in the bandage and wounding some intestine.

This patient progressed slowly but steadily, her highest temperature being 101·6°. She was ultimately discharged cured.

CASE 2. *Multilocular Cystic Disease of Left Ovary.*—G. D——, aged twenty-four, a domestic servant, was admitted on April 12th, 1886. The patient is thin and short. Her family history is good; she has always been healthy, and is unmarried. The abdomen has been increasing in size for twelve months, but this was not noticed by the patient until attention was drawn to it by others. For the last three or four months she has had pain in the right iliac fossa. Menstruation regular. A distinct tumour can be felt; dull on percussion. There is resonance in the right and left flanks, and two inches above the umbilicus. Fluctuation all over the tumour. The uterus is depressed, but movable from the tumour.

April 21st.—The A.C.E. mixture having been administered, a small incision was made in the abdominal wall for two inches and a half, and the cyst exposed and tapped. It was then found to be multilocular, and to have a solid-feeling growth, consisting of smaller cysts containing gelatinous matter, situated in the upper part of the tumour, and to the right side, this was about the size of a fœtal head. The pedicle was broad and thin; it was ligatured with China silk and returned. There was fluid in the cavity—not cystic,—which was sponged out; the wound was closed with silk sutures and dressed with iodoform. The fluid from the tumour measured 1 gal. 6 pts. The wound healed by first intention, the stitches being removed on the third day.

The temperature in this case rose to 102° shortly after operation, ever after being below 101°. The patient made a most satisfactory recovery, and was discharged from the hospital cured.

CASE 3. *Cystic Disease of Left Ovary; Dermoid Cyst.*—S. S——, aged thirty-two, was admitted on May 10th, 1886, having been sent by Dr. Lett. Married; no children. Menstruation regular. Has always been healthy until a year ago, when she began to lose flesh. Two months after this she noticed a swelling in the left iliac region, but as there was no pain she took very little notice of it. For the last three months it has been increasing rapidly, and causing pain in her left groin and loin. The abdomen measures 34½ in. at the umbilicus, and is occupied by a swelling partly solid and partly fluid—the solid portions being in the right hypochondriac and left lumbar regions. The percussion-note is dull all over the abdomen, except in the flanks and above a line drawn transversely two inches above the umbilicus. Uterus normal and freely movable.

On May 25th an operation was performed. The A.C.E. mixture having been administered, an incision three inches long was made, and the fluid withdrawn from a large cyst occupying the front of the tumour, which was still too large to be removed through the opening, so the incision was continued another inch. With some difficulty the tumour was removed, when it was found to be a dermoid cyst containing a large quantity of vernix caseosa—hair—bone, and partially developed teeth. The weight of the solid portion was 5 lb. 2 oz., the fluid being small in quantity. The pedicle was ligatured and returned, the cavity being thoroughly sponged out. The wound was closed with silk sutures, and dressed with iodoform and dry lint. A few adhesions to the parietal peritoneum were broken through, and others attached to the intestines were divided between double catgut ligatures.

The highest temperature after operation in this case was 100°. The patient convalesced satisfactorily, and was discharged cured.

Remarks.—Before operation the patients were carefully dieted, and in addition had baths containing carbolic acid. The operations were done in the small general ward in which the patient was to remain, the ward having been previously thoroughly disinfected. The temperature of the room during the operation was 70°, being afterwards kept at 65°. For a quarter of an hour before and during the operation the carbolic spray was at work, but not close to the patient. The hands of the operator and assistants were washed in carbolic solution, and the usual precautions with regard to sponges and instruments were taken. After the operation the patient was put to bed, and carefully nursed, watched, and fed either by mouth or rectum according to circumstances. It is not necessary to enter into the details of their convalescence; suffice it to say that they all responded well to the efficient nursing provided for them.

HULL ROYAL INFIRMARY.

SCALD OF THE LARYNX IN A CHILD; TRACHEOTOMY; RECOVERY.

(Under the care of Dr. LUNN.)

FOR the following account we are indebted to Mr. Edward Harrison, house-surgeon.

Charles C——, aged two years and four months, was admitted on Jan. 2nd, 1886, at 6.30 P.M. At 2.30 P.M. on the day of admission he attempted to drink from the spout of a kettle containing boiling water.

On admission there was some cyanosis and sucking in of the lower ribs during inspiration. He was at once put into a tracheotomy cot, with a steam kettle, in a warm room. At 8 P.M. the symptoms were much relieved. At 9 P.M. he became much worse; there was much cyanosis and sucking in of the chest walls during inspiration, and the breathing was stridulous. Tracheotomy was performed, and at once relieved him.

On the following morning the temperature was 103·4° F. This came down gradually day by day. For the first few days there was much bronchial discharge, so that the tube had to be cleared with a feather about every five minutes. His pulse was 150, and respiration 60 to 80. He was treated with brandy, ipecacuanha wine, and aromatic spirits of ammonia, and had poultices applied to the chest. On the 19th the silver Bryant's tube was changed for an indiarubber one, in which a hole was cut to allow of respiration through the larynx. On the 22nd he wore a cork in the tube all day, and on the 23rd the tube was removed and the wound allowed to heal. The after-progress was uninterruptedly good. He was discharged on Feb. 5th, well.

INTESTINAL OBSTRUCTION CURED BY INVERSION AND INJECTION OF AIR.

(Under the care of Mr. CRAVEN.)

Frederick F——, aged four, was admitted on Jan. 24th. The child was well and the bowels acted regularly daily until Jan. 15th, when they did not act. Vomiting began the same evening and continued until the day of admission, when it had become very offensive. No blood or mucus was passed. The child complained of abdominal pain, and refused to take any food.

On admission the face was flushed and looked pinched, and he was much emaciated. Abdomen distended; pain referred to umbilicus. Tongue red and dry; pulse small and frequent. He vomited once, but the vomit could not be collected; it smelt, however, stercoraceous. Under chloroform the abdomen was found to be distended and tympanitic all over; no sausage-shaped tumour to be felt. Per rectum a few scybala were removed from its lower part, and a mass was then felt which seemed to be scybala covered with mucous membrane. The child was then inverted and air pumped into the bowel; this could be felt entering by the hand placed on the abdomen. After a short time the air seemed to enter more easily, judging by the force required to squeeze the syringe. The inflation was then discontinued and the finger again introduced into the rectum, where the fold of mucous membrane had disappeared, and some free scybala were found and removed. The finger could now be passed above the brim of the pelvis, where more scybala were lodged. An enema of a pint of warm water was then injected, which brought away some hard lumps, but no blood or mucus. The abdomen was rubbed with an oiled hand, which assisted in expelling the water and a small formed motion. Three minims of tincture of belladonna and three of tincture of opium were given in a teaspoonful of water, but were immediately vomited; the vomit was stercoraceous. A twelfth of a grain of morphia and of belladonna was introduced as a suppository, and the child passed a good night.

Jan. 25th.—The opium and belladonna was

ordered three times a day; a teaspoonful of milk every half hour, Brand's essence, and brandy.

26th.—Vomited after drinking a quantity of milk in the absence of the nurse.

28th.—Bowels acted twice. Is able to take more food, and is gaining flesh.

Feb. 2nd.—Bowels acted freely. Is able to take chicken and egg, &c.

7th.—Bowels have acted daily since the 2nd. Has no pain; abdomen soft and natural. Has gained three pounds in weight since Feb. 1st.

14th.—The child was discharged well.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

The State of the Femoral Artery after Ligature for Popliteal Aneurysm.—Richter's Hernia or Partial Enterocele.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Mr. W. S. SAVORY contributed a paper on the effect upon the Femoral Artery of its Ligature for the cure of Popliteal Aneurysm. The paper contained an analysis of twenty-six specimens in the museums of the London hospitals in which the femoral artery had been tied in Scarpa's triangle for the cure of popliteal aneurysm. Of these specimens seventeen were complete. Of these seventeen, the artery was pervious throughout in thirteen, and partially closed in four. In none was the artery impervious throughout. Of the seventeen specimens fifteen were cured. In these the artery was pervious in eleven and partially closed in four. In two the operation had failed to cure, and the artery remained pervious in both. Mr. Savory gave details of cases from his own practice. In one case, a man aged thirty-seven, a hawker, with popliteal aneurysm, the pulsation of which could be reduced by controlling the femoral, there was a three months' history. In February the femoral artery was tied in Scarpa's triangle. A slight return of pulsation occurred on the third day. One year afterwards the aneurysm had returned, with slight pulsation, and formed a bigger tumour. It was treated by rest and elastic bandages without much effect, for six months later it was in the same state. Then the patient was anæsthetised, and the leg bandaged with Esmarch's apparatus; the popliteal artery was tied in the upper part of the popliteal space. This operation was perfectly successful. In a second case the artery was ligatured first in Scarpa's space, next in Hunter's canal, and finally a third time in the upper part of the popliteal space. The question of reconsidering the method of ligaturing the popliteal artery for popliteal aneurysm ought to be entertained. Mr. Savory was disposed to think that this method would prove most useful, and said he should generally prefer to adopt it in future.—Mr. G. D. POLLOCK said that in his experience ligature of the external iliac artery was very successful in obliterating the vessel below.—Mr. JOHN CROFT concluded from the evidence in Mr. Savory's paper that ligature of an artery in its continuity should be practised by the application of two ligatures, with division of the vessel between. An additional element of safety was added when the two ligatures were used.—Mr. J. W. HULKE thought that Mr. Croft's remarks were beside the subject of the paper. The author's paper appeared to him to point to the conclusion that the best method of treating popliteal aneurysm was by tying the artery close to the aneurysm. Doubtless in past times such operations were frequently fatal from secondary hæmorrhage and other accidents, but then it was likely that the ligatures were not thoroughly aseptic.—Mr. JOHN WOOD said that the outcome of Mr. Savory's valuable paper was a return to the practice of Anel, who ligatured the artery just above the aneurysm. But since Anel's time a complete revolution had taken place in the treatment of surgical wounds. The employment of the method of double ligature, with division between, prevented tension of the parts around the artery, and strict antiseptics also prevented inflammation; hence the chief dangers of the original Anel's operation were removed. The artery should be tied before the aneurysm attained an enormous size, lest secondary hæmorrhage and gangrene might result from the great [illegible] Mr. Croft were not so irrelevant to the paper as Mr. Hulke seemed to think.—Mr. THOMAS SMITH considered that ligature of the popliteal instead of the femoral artery was preferable for popliteal aneurysm; the operation was not difficult with the modern means at our disposal, and by the use of Esmarch's bloodless method. It was much more likely to produce a radical cure. He had ligatured this vessel in two or three other cases. In one he had previously ligatured the femoral. He was very glad that Mr. Savory had come to practise the method of double ligature with division between. The fact that the artery was pervious beyond the ligature was stated in recent books, and especially in Messrs. Ballance and Edmunds' pamphlet.—Mr. A. A. BOWLBY said that Mr. T. Smith had also tied the popliteal artery as a primary operation in one case of popliteal aneurysm. The artery was tied in the upper part of the popliteal space; the return of pulsation in the tibial arteries occurred rather sooner than when the femoral was tied; the aneurysm was cured perfectly. He alluded to one pathological point as to the condition of the artery just above the aneurysm; it was likely to be fully as healthy as the artery in Scarpa's triangle.—Mr. C. BALLANCE said that in his numerous experiments on the ligature of large arteries in their continuity in animals he had never found the artery obliterated for any distance beyond the ligature.—Mr. W. S. SAVORY, in reply to Mr. Smith, said that his paper dealt with the femoral artery, whereas Mr. Ballance's experiments were concerned with other arteries. The variability of the result would depend largely on the artery tied. He was not aware that any ordinary book stated that the artery was pervious from the ligature to the aneurysm. In reply to Mr. Pollock, he was not prepared to state the proportion of figures in which the femoral was pervious or impervious after ligature of the iliac artery. He agreed with Mr. Hulke that his paper was in no way concerned with the employment of two ligatures instead of one. The evidence on that point was in favour of one ligature, and of silk or twine over any form of animal membrane. It was true that in one case he had recently ventured to depart from his usual practice, but if he had to tie the femoral artery to-morrow he should use but one, and that a silk or twine ligature. He thought that the introduction of antiseptics and of the double ligature into a discussion on his paper was irrelevant.

Mr. FREDERICK TREVES read a paper on Richter's Hernia or Partial Enterocele. In this form of hernia a part only of the circumference of the bowel is engaged in the hernial orifice and there strangulated. The strangulation may be complete, and may proceed to gangrene without the lumen of the bowel being entirely occluded. The nomenclature of this rupture is obscure. By the majority of English writers it receives the title of Littré's hernia. The hernia described by Littré in 1700 was not of the character now under notice, but was an example of the escape into a hernial sac of a Meckel's diverticulum. These two varieties should be kept quite distinct. The author traces the history of these forms of rupture as displayed in surgical literature. The name of Richter's hernia is proposed, since the first scientific recognition of the condition was due to that surgeon. In Richter's hernia the small intestine is involved, and is held by that part of the gut that is most remote from the mesentery. The condition is met with more frequently in women than in men, and in femoral than in inguinal ruptures, is limited to adults, and occurs in recent as well as in old-standing protrusions. The mode of formation of the hernia was discussed, and the question of the formation of diverticula considered. The author described four cases that occurred in his own practice. The account of the clinical and pathological aspects of the condition was based upon the examination of thirty-three recorded cases. The symptoms tend to assume a milder character than is observed in the usual form of strangulation. The vomiting is slighter, less frequent, often of late onset, and is very rarely feculent. Hiccough is uncommon. The bowels may remain open during the whole progress of the strangulation, or may act occasionally, or will respond to aperients. In certain instances persistent diarrhœa may exist. Tympanitic distension of the abdomen is uncommon. The hernial tumour is very small, and often not recognised. The gut is practically irreducible by taxis, and, if prolonged efforts are employed, reduction *en masse* not unfrequently occurs. The mortality is exceedingly high, being represented by 62·2 per cent. This depends upon the difficulties in the way of diagnosis, upon the irreducibility of the gut, and upon the remarkable frequency of gangrene. The mortality after

herniotomy is proportionately high. The special features in the treatment are considered. The hernia deserves notice on account of the peculiar features involved in its pathology, its special clinical aspect, its grave prognosis, and the light that it throws upon the production of strangulation symptoms in general.—Mr. J. W. HULKE said that Littré described in 1700 hernia of a Meckel's diverticulum, but a second form of partial hernia was described in 1714 by Littré also, in which it was distinctly stated that the enterocele was not a loop of colon, and that not the whole of the circumference of the bowel was included. He rather thought that Richter did not fully comprehend the matter. In his second volume, published in 1779, references were made to small hernia in which the whole circumference of the bowel was not included as existing between the xiphoid cartilage and umbilicus, which were sometimes omental and sometimes intestinal. Richter spoke of but one case, and of that he gave no description; probably, therefore, he neither operated on it nor dissected it. Reike described congenital and acquired diverticula; the latter were also known as partial enterocele. Ruysch treated of hernia lateralis, which was doubtless the same condition. Dieffenbach had a separate chapter on this affection, and had had two cases in his own practice. This form of hernia could hardly be called very rare. It was exceedingly difficult to distinguish it from an ordinary hernia, and he doubted if we could depend on the symptoms in a differential diagnosis.—Mr. TREVES, in reply, agreed with Mr. Hulke that a great deal of confusion had existed on the subject of the original description of the hernia; but he also thought that if Mr. Hulke had heard certain parts relating to this question, and which had been suppressed in the reading of the paper owing to the great length of the communication, he would have concurred with him (Mr. Treves) in assigning the first accurate description of the hernia to Richter.

CLINICAL SOCIETY OF LONDON.

Diphtheritic Paralysis and Heart Disease.—Acute Myositis.—Gastric Ulcer.

AN ordinary meeting of this Society was held on the 10th inst. Mr. Thomas Bryant, F.R.C.S., President, in the chair. Dr. Montagu Murray and Mr. Frederick Treves were elected auditors for the annual general meeting.

Dr. HERRINGHAM read a paper on two cases of Diphtheritic Paralysis with Heart Affections and Clonic Movements. On admission there was in both great weakness of the legs, with a tottering gait, and the deep reflexes were abolished. The legs were in other respects normal. In one case, a girl aged nine, eight or nine weeks from the beginning of the weakness the knee-jerk was suddenly present in excess, and with it ankle-clonus. The jerk became normal in four weeks; the clonus vanished in six weeks. The heart, which was normal on admission, became affected during her stay in bed with mitral disease, and so remained after an interval of ten months. The other case, a boy aged four, did not ever show ankle-clonus or extensive jerk, but a few days after his discharge he returned with a faint mitral murmur. If, as is now supposed, diptheritic paralysis is due to disease of the central grey matter of the cord, this case is in favour of the theory that the deep reflexes depend upon this part, and are increased in disease not because the brain's veto cannot travel down the cord, but because the grey matter is itself altered.—Dr. S. COUPLAND considered that if the murmur and cardiac enlargement occurred during the diphtheritic attack, myocarditis might have been the cause. Diphtheritic paralysis was more likely to supervene if cases were not treated from the first as Dr. Abercrombie had pointed out. Loss of the knee-jerks was a constant symptom of the paralysis. He had seen cases which were ataxic rather than paralytic.—Dr. ANGEL MONEY had made some observations on the mode of disappearance of the knee-jerk in diphtheritic paralysis. The jerk became excessive—an illustration of the "irritable weakness" of old authors—prior to its being lost. He thought this would throw some light on the occurrence of phenomena of exaggeration preceding the proper re-establishment of the jerk when the paralysis had passed away. In some cases the tap on one ligamentum patellæ was followed by excessive contraction of the triceps on that side and by a well-marked contraction of the triceps of the other side, showing that the nerve discharge in the cord had passed across from one anterior horn to the other.—Dr. MACLAGAN thought diphtheritic paralysis was anæmic in origin in many cases. Ataxic paralysis occurring after diphtheria disappeared under tonic treatment, as in the case of a gentleman, aged eighty-two, that had been under his care. Diphtheria affected the myocardium, and so might generate a murmur, as chorea did by causing irregular spasm. He asked whether there had been albuminuria in the cases.—Dr. PERCY KIDD objected to the view that diphtheritic paralysis was of anæmic origin. In many fatal cases there were changes in the anterior spinal cornua, as Déjérine, Landouzy, and himself had shown. Neuritis of peripheral nerves and changes in the anterior and posterior roots of nerves had been observed in cases of diphtheritic paralysis.—Dr. T. BARLOW could not allow that the paralysis was of anæmic, functional origin. In other ordinary cases of anæmia such symptoms as nasal voice, failure of accommodation, and paralysis of oculo-motor nerve were not observed, and such a combination would suggest diphtheritic paralysis, not anæmia. He could confirm Dr. Money's observation to the effect that there was a period of irritability preceding the loss of the knee-jerk. He considered that dilatation of the myocardium would explain the murmurs observed in diphtheria.—Dr. S. WEST also agreed that affection of the muscular substance of the heart would best explain the murmurs, were it not that they had lasted ten months; on the other hand, the fact that the murmurs vary so much was in favour of their myocardial origin.—Dr. HERRINGHAM, in reply, said that the enlargement of the heart persisting so long, and the existence of an accentuated second sound, seemed to him to point to the valvular origin of the heart disease.

Mr. TREVES read a paper on Acute Myositis. A carman, aged twenty-two, was admitted into the London Hospital with "an inflamed arm." Three weeks previously he was exposed to severe cold when driving, and had been wet through. The chief symptoms were rigor, malaise, fever, loss of power in the arm, and cramp-like pain. Similar pains appeared in the calves of both legs. The affected parts were swollen and tender. The trouble in the legs soon subsided, but the swelling in the left arm increased. The muscles, notably the deltoid and biceps, were enlarged, and were very hard and tender. There was fever. Under treatment, extending over three weeks, the induration in the muscles gradually disappeared without suppuration, and the man made a complete recovery. Mr. Treves considered the case to be one of acute myositis, and entered fully into the points raised by the differential diagnosis. He divided acute myositis into the following varieties: 1. Simple myositis due to injury or the direct extension of inflammation. 2. Myositis from cold. 3. Infective myositis. This interesting affection has been fully described by Connor, Hayem, and Scriba. The usual centre of infection is a common boil, and the similarity of the disease to acute osteo-myelitis may be considered to have been demonstrated. 4. The myositis of trichinosis. The present patient was in the habit of eating a quantity of ill-cooked pork, and Mr. Treves discussed the phenomena of cases of mild trichinosis that undergo spontaneous cure. 5. Secondary myositis—i.e., that attending certain eruptive fevers,—the myositis of syphilis, and the muscle inflammations of pyæmia, puerperal fever, scurvy, glanders, and ulcerative endocarditis. The general phenomena of true muscle inflammation were considered, together with the usual seats of that inflammation and the clinical evidences of the disease.—Dr. DE HAVILLAND HALL said that acute glossitis had been clearly traced to "cold."—Mr. R. J. GODLEE said that in a case of myositis ossificans occurring in a child the disease began as a tender swelling in the muscle, and it was supposed that a tumour was developing.—Dr. EWART asked whether the cases described were true myositis or perimyositis. In rheumatic conditions like lumbago the fibrous sheath was probably affected. He thought that a distinction of a pathological kind into parenchymatous and interstitial inflammations would improve the classification.—Dr. GOODHART spoke of two cases, both of middle-aged men with a suspicion of gout, in whom severe pain in one calf of the leg was the preface to a hard indurated condition of the muscle, which lasted from two to three weeks, and in one of them possibly suppuration occurred.—Dr. COUPLAND mentioned a case of embolism in a middle-aged man suffering from ch[illegible] There was sudden pain [illegible] swelling, which

rapidly increased, and suggested hæmorrhage. The artery was tied, but the necropsy showed that there was no rupture of the artery. There had formed an embolic aneurysm of a branch of the brachial artery. Would Dr. Ewart include in the term myositis the remarkable degeneration in muscle that occurred in typhoid and other fevers?—Dr. S. PHILLIPS referred to a case with contracted elbows and tender muscles, apparently due to a past gonorrhœa. In another case a young man was seized with intense pain and tenderness in both calves, suggesting deep phlebitis; but the signs disappeared; the patient had gonorrhœa.—Dr. S. WEST spoke of the case of a young man with an obscure acute affection of muscles. It did not appear to be simple rheumatic fever, for the muscles of the arms, calves, and thighs were tense, hard, and extremely tender. There was high fever and rapid wasting of the muscles. Albuminuria and œdema were also present. Trichinosis was thought of, but the case must remain undiagnosed.—Mr. FRED. TREVES specially avoided speaking of glossitis. He could not grasp the idea of glossitis from cold. Erb had published an account of the anatomical changes in myositis, and had shown that the true muscular tissue was involved. Did muscular rheumatism set in with a rigor and high continued fever lasting two or three weeks? Did such symptoms occur in gonorrhœal rheumatism?

Dr. MONTAGU MURRAY read a paper on a case of Gastric Ulcer with unusual complications. An anæmic girl, aged twenty-three, was admitted on Feb. 15th with indefinite gastric symptoms. On the 16th the temperature rose suddenly to 103·6°F., a sharp pain was experienced in the left side, and a pleuritic rub could be heard. On the 17th the abdomen was found to be tender and swollen. During the 17th and 18th there was severe vomiting. Hæmatemesis began on the 19th. At first the blood was bright red, and the amount ten ounces, but subsequently the quantities were smaller and the colour much darker. Patient rapidly became weaker, and died on the 22nd. Vomiting ceased four hours before death. At the post-mortem acute left pleurisy and acute peritonitis were found. On opening the stomach a small ulcer was seen at the cardiac end; its outline was roughly circular, its diameter an inch, its wall thickened and precipitous, and its floor composed of peritoneum, perforated in the centre by an aperture one eighth of an inch in diameter. Three questions were discussed: (1) The age of the ulcer; (2) the time of the perforation; (3) the connexion between the ulcer and the inflammation of the serous membranes. 1. It was argued that while the symptoms on admission did not clearly point to ulceration, yet when considered with the subsequent history and the post-mortem appearances, it was clear that the ulcer must have been present at that time. The immediate cause of the hæmatemesis was probably the straining during the severe vomiting which preceded it. 2. That perforation was a cause of the pleurisy and the peritonitis was rejected on the ground that the hæmatemesis did not begin until after the onset of the three complications; that the vomiting did not cease until four hours before death; and that there was no evidence of extravasation from, or of inflammation in the neighbourhood of, the perforation, which was believed to have coincided with the cessation of vomiting. 3. The connexion of the ulcer with the pleurisy, and peritonitis was rendered probable because of the existence of communicating lymphatics; the occurrence of left pleurisy with an ulcer at the cardiac end; the rarity of the two conditions occurring simultaneously; and the absence of any other discoverable cause.—Dr. MITCHELL BRUCE said that cases of perforation and peritonitis were of great interest, not only to the physician, but also the surgeon. In Dr. Murray's case it seemed clear that peritonitis preceded perforation.

The following card specimens were shown:—Dr. A. H. Robinson: Venous Angioma of Leg. Mr. Pearce Gould: Branchial Fistula of Pinna of Left Ear. Dr. Herringham: Mitral Disease after Diphtheria. Mr. Harrison Cripps: Valvular Left Lumbar Colotomy.

MEDICAL SOCIETY OF LONDON.

Treatment of Lateral Curvature of the Spine.—A New Method of Excision of the Knee.

AN ordinary meeting was held on the 6th inst., Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

MR. WM. ADAMS read a paper on the Advantages of Gymnastic Exercises in the Treatment of Lateral Curvature of the Spine. The author recommended a combination of the various methods, or so-called systems, of treatment—such as recumbency, muscular exercises or gymnastics, and mechanical support,—rather than relying upon any one system exclusively. The degree in which they should be combined must vary according to the nature of the case, age, and other circumstances. For gymnastic exercises in the horizontal position Mr. Adams had recently employed an improved exercising plane, made by Mr. Ernst at Mr. Adams's suggestion, and exhibited to the Society. The plane is 6 ft. in length, and made on the incline, having a sliding board, half the length fitted with rollers, and movable up and down the inclined plane in metal grooves at the sides. The exercise essentially consists in the patient drawing herself up the inclined plane whilst the body is resting on the sliding board or movable stage. This movement may be repeated several times—say from five to ten at the commencement—after short intervals of rest, and gradually increased, but always avoiding fatigue. Exercises on the plane and the trapeze bar may be repeated two or three times a day, and lasting half an hour each time, constituting a plan of home gymnastics. Mr. John Shaw was the earliest advocate of horizontal gymnastics, and illustrated an exercising plane plate in his work in 1823. This was modified by Mr. Ainsbury, but the plane exhibited embodied the principle of Mr. Shaw's plane with several useful appliances for special exercises. By the combination of recumbency with gymnastic exercises, and the addition of mechanical support in some form best adapted to the requirements of each case, the spinal curvature, when slight, would be removed, and in the later stages its progress would be arrested.—MR. EDMUND OWEN considered that jackets of poroplastic material and plaster-of-Paris should not be employed, for the muscles were by such supports rather weakened than strengthened.—MR. BERNARD ROTH expected to hear of a new departure, and was disappointed. He objected to the systematic employment of the recumbent posture, as not calculated to promote muscular tone. The treatment he advocated would be found in detail in Mr. Heath's Dictionary of Surgery.—MR. JAMES BLACK was convinced that posture and exercise were the correct treatment.—MR. WALTER PYE thought there were severe cases of scoliosis that necessitated the use of some spinal support.—The PRESIDENT said that Dr. Little had advocated gymnastics for the treatment of spinal deformity twenty-five years ago.—Mr. W. ADAMS said that a combination of different systems for different cases was the correct method of treatment. He did not believe that muscular exercises alone could remove confirmed slowly-produced osseous deformities. The instruments were merely used as passive supports.

MR. HERBERT ALLINGHAM read a paper and showed cases of a New Method of Excision of the Knee. The operation consists in making a vertical incision over the joint in front, beginning two or three inches above the patella, and prolonged over the patella down to the tubercle of the tibia. The knife splits right through the quadriceps tendon above the patella into the synovial pouch there. The soft tissues over the patella are divided to the bone, the knee-cap sawn through, dividing it into two lateral halves, then the ligamentum patellæ is also split down to the tubercle of the tibia. By this means the joint may be thoroughly exposed by drawing outwards each half of the patella and associated structures to its corresponding side of the joint. The two halves of the patella are wired when the operation is finished. He claimed the following advantages for the operation: 1. The attachments of the fascia lata, the lateral ligaments, and the prolongation of the vasti to the tibia and fibula are not divided, and consequently there is much more support to the joint during the healing process, and when the leg is well. 2. Above the patella the synovial pouches are well opened, and all the synovial membrane can be thoroughly removed. 3. Dislocation of the tibia backwards and tilting of the femur forwards, which commonly occur after the operation, are thus prevented. 4. The joint and the end of the bones can be thoroughly examined, which was not possible by the method of lateral incisions. 5. The undivided [illegible] is a strong antagonist to the hamstring [illegible] should the splint be left off the leg is much less [illegible] bent. 6. Progression is greatly [illegible] of the quadriceps being neither [illegible] ened, as must necessarily take [illegible] or U shaped operation [illegible] as we hope after excision

to obtain movement in the knee-joint, the chances, Mr. Allingham thought, of such a result being brought about will be greatly facilitated by the operation described. In future operations Mr. Allingham said he would remove thoroughly the whole synovial membrane, and only dig out with a gouge the diseased spots on the cartilage, and should not in any way interfere with any of the cartilage that looks healthy. If the crucial ligaments are not extremely diseased they should be left undivided. The joint should be kept at absolute rest until the wound has healed, when passive motion may be commenced.—Mr. WILLIAM ADAMS thought nothing could be better than the result in the case shown.—Mr. EDMUND OWEN considered that the hæmorrhage would be less from the joint in Mr. Allingham's method, which he should certainly practise, but rather as erasion than excision of the joint.—Mr. J. H. MORGAN always avoided excision as far as possible, and this would certainly be obtained by Mr. Allingham's method, which he hoped in future to try.—Mr. ALLINGHAM, in reply, said that a good view of the whole of the interior of the joint could be obtained.

Intra-peritoneal Hæmorrhage in a Newly-born Infant.—Anæsthetics.

At the ordinary meeting held on Monday last,

Dr. KESER read notes of a case of Intra-peritoneal Hæmorrhage in a newly-born infant of the male sex. The child was born at full term on April 29th, and the labour was normal. The child was in a state of apparent asphyxia, but respiration was easily established. There was slight subconjunctival hæmorrhage on the right side. On May 1st swelling of the scrotum was observed, and the penis was œdematous. On May 4th the scrotum was much more swollen. The temperature in the rectum was 98°. The abdomen became swollen and the lips were pale. The cord separated on that day without hæmorrhage. The child died on the ninth day. There was an ecchymosis in the middle of the back. Melæna or hæmatemesis was not observed. The spleen was enlarged, and measured 9 cm. in length, 5 cm. in breadth, and 2 cm. in thickness; the upper half was swollen and congested, and very dark from hæmorrhage, which seemed to have come from a lesion that looked like an infarct. According to Birch-Hirschfeld the size of the spleen in a child eight days old was 4 cm. by 3 cm. The peritoneal cavity was full of dark fluid blood, the amount escaping being about 8 oz. The splenic artery appeared to be normal, as well as the other branches of the aorta. There were no hæmorrhages or infarcts in any other organs. The mother had had eight pregnancies. The first child died at the age of eighteen days, but the cause of death was unknown. After this child five stillbirths occurred. The seventh child was born at full term, was nursed by the mother, and remained well until the end of the fourth week, when epistaxis set in, followed by hæmatemesis and melæna; large ecchymoses appeared on the trunk and limbs, and death ensued after a week's illness. The mother had no tendency to metrorrhagia or to any other form of hæmorrhage. There was no hæmophilic history so far as could be obtained. Spontaneous rupture, as probably occurred in the case recorded, was very rare. Ritter, who collected 132 cases of hæmorrhage in new-born children, had never observed it. Grandidier had observed intra-peritoneal hæmorrhage, but the source of the blood was not discovered. Steffen found a rent in the convex surface of a soft spleen in one case of intra-peritoneal hæmorrhage. Billard found at the necropsy of a child six days old a large quantity of blood in the stomach and intestine, and an enlargement of the spleen, which was ruptured; there was but a tablespoonful of blood in the peritoneal cavity. Dr. Keser could not detect the source of embolism, but believed that there was an infarct in the spleen as the result of arterial obstruction.—Mr. J. H. MORGAN related a case of icterus neonatorum attended with severe hæmorrhages, and due to congenital obliteration of bile ducts.

Mr. MARMADUKE SHEILD read a most elaborate and comprehensive paper on the Administration of Anæsthetics. He indicated the methods to be employed and the agents to be used; and the various operations, circumstances, or diseases which required special plans of administration were dealt with *seriatim* and in detail. He advised Clover's apparatus and ether in the great majority of cases.—Mr. R. BRUDENELL CARTER referred to the difficulties attending operations on the eye when ether was used, and also gave an account of some painful occurrences due to chloroform. Happily, the use of general anæsthetics in ophthalmic surgery was now almost entirely unnecessary.—Mr. BAILEY agreed that ether in Clover's apparatus was the most useful agent. If chloroform is to be given, ether should precede its administration. In young children chloroform must be administered with caution, and indeed should be preceded by ether.—Dr. HEWITT thought that a sudden transition from nitrous oxide to ether was a method to be avoided. The transition should be gradual. Some anæsthetic mixtures were most useful.—Mr. M. SHEILD, in reply, said that some cases of death under anæsthetics were not due to the anæsthesia, but to something in the operation, or to some morbid condition in the patient. Of the value of the expiratory valve in Clover's apparatus he was not quite sure.

OPHTHALMOLOGICAL SOCIETY.

Symmetrical Swellings about Lacrymal Glands.—Atrophy of Iris.—Lamellar Cataract with Triradiate Structure.—Choroidal Hæmorrhage.—Eyes of School Children.—Ecchymosis and Œdema of Eyelids without obvious cause.—Hydatid Cyst of Orbit.—Quinine Amaurosis.

AN ordinary meeting of this Society was held on the 9th inst., Mr. J. Whitaker Hulke, F.R.S., President, in the chair.

Mr. SAMUELSON, of John-street, Manchester, presented to the Society the cover of the blotting-pad and the ophthalmoscope of von Graefe.—Mr. HULKE presented the various ophthalmoscopes shown to the Society at the first meeting of the session, when he gave his presidential address.

Mr. ADAMS FROST showed a case of Symmetrical Hypertrophy in the neighbourhood of the Lacrymal Glands. The growth had been noticed for two months, but no treatment had yet been of avail. It was possible that the swellings were tumours of the same nature as those found in the carotid gland, but here both sides were affected.—Mr. H. POWER had shown a very similar case at the last meeting but one (THE LANCET, p. 823); there was chiefly hypertrophy of fibrous tissue.

Mr. W. H. JESSOP showed a case of Congenital Atrophy of the Iris, in which the anterior epithelial layer was absent and the well-marked radial structure of the pigment exposed. The vision was perfect.

Mr. W. H. JESSOP also showed a case of Lamellar Cataract with the triradiate structure very marked. He was uncertain as to the correct disposition of the lens sectors. The Y-shape was inverted in front and upright behind according to Schwalbe and Quain's Anatomy, but the opposite obtained in the case shown.

Mr. A. Q. SILCOCK showed a case of Hæmorrhage into the Choroid of semicircular shape, situate nearly at the posterior pole of the eye. The question was whether the extravasation was from choroidal, as the Germans said, or retinal vessels, as the English held.—Mr. NETTLESHIP asked for the reasons for attributing the extravasation to a choroidal vessel. The fact that the retinal vessels disappearing in the hæmorrhage were exceedingly tortuous, whilst vessels away from it were normal, was surely in favour of the retinal origin. In some cases a thin layer of retina existed in front of the extravasation. If choroidal, a layer of nerve fibres should be found in front of the hæmorrhage. In some cases a large retinal vessel, previously invisible, was found to have thickened coats or to be actually blocked when the hæmorrhage was absorbed. The shape—circular—favoured the retinal origin, for there was no reason why this shape should occur in the choroid.—Mr. W. H. JESSOP said that in the last volume of the Transactions he had recorded a case of hæmorrhage in which the vision was Jaeger 20. Now all the hæmorrhage had disappeared, and small white spots along the vessel that was tortuous were all that remains; but vision was now perfect. He believed the retina was the seat of the extravasation.—Mr. H. POWER believed such hæmorrhages were choroidal, for a thin membrane, which was probably the retina, was invariably situate in front of them. In Mr. Jessop's case, with perfect recovery of vision, the choroidal view was also favoured, for if the hæmorrhage had been retinal perfect recovery of vision would hardly be possible.—Dr. J. ANDERSON mentioned a case of chronic Bright's disease in which a large hæmorrhage appeared to be in the retina when the fundus was examined after death, though the specimen had not yet been microscoped.

Mr. W. LANG showed a case, in a woman aged twenty-five, of Post-neuritic Atrophy of the Optic Nerve, with preservation

of good vision. There was a history of fits before the age of seven, and also of "bilious attacks," with vomiting and attacks of giddiness, during the last five years.

Mr. JACKMAN read a paper on the Eyesight of School Children, based on the examination of 456 children. The cases of ametropia were carefully tested in all, with and without a mydriatic, with the exception of the 32 cases of astigmatism in the Coggeshall Boys' School. In any doubtful case the cornea was examined through a + 10 D lens. The colour sense was examined by means of coloured wools. The 456 children ranged from the age of five to fourteen years, and were scholars at the seven following schools:—Coggeshall National Boys'; Coggeshall National Girls'; Coggeshall British Boys' and Girls'; Kelvedon National Boys'; Kelvedon National Girls'; Kelvedon British Boys and Girls'; Feering Boys and Girls'. The children were not in any way selected for examination. The statistics showed the following percentage for each defect: Ametropia = 19·2; hypermetropia = 6·5; myopia = 2·17; astigmatism = 10·5; anisometropia = 5·04; colour-blindness = 1·7; defective internal rectus = 8·7; strabismus = 2·8. Plans of the seven schools were taken, and the ratio between the window-space and the floor-space noted for each school. Upon comparing these results with the percentage of cases of myopia in each school, no connexion could be traced between the two, as was evident from the following table:—

School.	Window-space to Floor-space.	Myopia.
Coggleshall Boys' ...	1 square foot : 12 square feet ...	2·1 per cent.
Kelvedon Boys' ...	1 ,, : 7·7 ,, ...	0·0 ,,
Coggleshall British ...	1 ,, : 6·7 ,, ...	2·5 ,,
Kelvedon British ...	1 ,, : 6·5 ,, ...	2·17 ,,
Kelvedon National Girls'	1 ,, : 5·8 ,, ...	1·88 ,,
Feering	1 ,, : 5·3 ,, ...	0·0 ,,
Coggleshall Girls' ...	1 ,, : 5·0 ,, ...	7·6 ,,

Neither could the positions in which the children sit with regard to the positions of the windows be shown to affect directly the amount of myopia in the several schools. The school books used in all the schools were of good print, with the exception of the copy of Shakespeare used for the higher standards; but this was used in the schools which give a low percentage of myopia, as well as those which showed a high percentage. It was therefore necessary to seek further for a cause as to the difference in the amount of myopia noticed in the seven schools under consideration. Of all the Coggeshall school children examined, the percentage of myopia was =3·4; in Kelvedon, =1·2; in Feering, =0. The Coggeshall children were of very low vital stamina; their parents were, as a rule, poor, and the children were raised upon ill-nourishing food, the absence of milk in their diet being particularly noticeable; moreover, their surroundings more nearly approached those of children resident in larger towns. The Kelvedon children were of better constitutions, and milk was more easily obtained in this village. The Feering children were of still better constitutions, and their surroundings more conducive to good health. It therefore seemed probable that the amount of myopia was directly dependent upon the constitutional stamina of the children. In connexion with this point, it was of interest to refer to the percentage of cases of defective internal recti muscles, as a similar ratio was apparent between the constitutions of the children and this defect. In the Coggeshall children the percentage was 12·5; in the Kelvedon, 11; in the Feering, 0.—Mr. ADAMS FROST said that if the vision were tested without the use of atropine, the percentage of myopia was much higher than when atropine was used. Mr. Jackman deserved commendation for drawing attention to other causes than deficient lighting in the production of myopia.—Mr. H. POWER thought that the effect of close work upon girls should be taken into account in appraising the etiology of myopia. One young lady hemmed handkerchiefs, in which there were seventy-two threads to the inch; two at a time were taken up in each stitch, and so vision would have to be much more acute, and the eyes "tried" more in girls, for the letter M would occupy $\frac{1}{20}$ in., the stitch only occupying $\frac{1}{36}$ in. Therefore defective light was assisted by the quality and character of work required to be done.—Mr. EDGAR BROWNE (Liverpool) alluded to certain fallacies in estimating the influence of light in the production of myopia. Different parts of the house or school were unequally lighted. If every inmate of the school could see a strip of sky, there would probably be sufficient light for all purposes. This was an instruction to be given to the architect. Girls in sewing hold the article within six inches of the eyes for fear of pricking their fingers, and of punishment if a fa[illegible] of sewing fine things was far more exhausting and exciting to the organs of vision.—Mr. JACKMAN admitted that sewing and lace-making, especially of black lace, were very trying to the eyes.

Dr. ORMEROD read a paper on Ecchymosis and Œdema of the Eyelids without obvious cause. The prominent feature of the affection was that the patient complained of his eye turning black as if from a blow in the course of a night or in a few hours' time. On examination, ecchymosis of the eyelids, or in some cases œdema only was found. Usually pain in the eye or the head preceded the attack, but no injury and no fit. The attacks might be recurrent. Three cases were given where this was witnessed: a man, aged seventy-two, suffering from vertigo and pains in the head; a woman, aged fifty-four, suffering from paralysis of one arm; a woman, aged fifty-five, epileptic. Other cases were mentioned where similar "black eyes" were complained of by the patients. A definite explanation was not attempted, but the possibility of a connexion with migraine was suggested by an observation of O. Berger's. The ecchymoses of tabes dorsalis were quoted to show that extravasation of blood might be caused by disease of the nervous system.—Dr. COUPLAND referred to a case of hysteria in a woman. There were spontaneous hæmorrhages into the skin on both sides, which could not be explained satisfactorily.—Mr. HULKE thought different cases might be grouped together accidentally; in individuals above middle age diseased vessels were common, and straining or other mechanical acts might play a part in causing ecchymosis. In nervous disease, too, affecting one part of the body, the vessels on that side might presumably be more liable to rapid change, and hence become deteriorated in structure.—Dr. HADDEN referred to the case of a young medical man in whom the eyelids became swollen, and remained so for two weeks; no cause could be ascertained, and there certainly was no albuminuria. In another case, that of a young woman aged twenty-four, who came for diarrhœa, there was only frequent defecation, with some œdema about the face. She also suffered from bronchitis. When last seen at the Marylebone Infirmary, myxœdema was considered: there was œdema of the legs, with bronchitis, and œdema of the eyelids, but this last symptom cleared up in a week; the patient died, but the thyroid was healthy. In neither of the cases mentioned was there ecchymosis. He had seen similar local fugitive œdemas in children. The question of their nervous origin was worth entertaining.—Dr. ORMEROD, in reply, said, though the cases occurred in people beyond the middle age, he did not think that arterial disease had any influence in the causation of the hæmorrhages.

Dr. W. A. BRAILEY exhibited specimens, and gave an account of a case of Hydatid Cyst, causing Proptosis, with Cysts in Liver, Lungs, Brain, and other Viscera, and Unilateral Optic Neuritis. The patient, a female child, aged two, was generally healthy till fourteen weeks before death; then the left eye did not close properly during sleep, and she used to wake up occasionally with a screaming fit. Eight weeks later she was admitted into Guy's Hospital, where, on Sept. 28th, she had a convulsion. Then, being taken with whooping-cough, she was transferred to the Evelina Hospital. It was noticed that the liver had a bossy feel, the nodules varying in size from a pea to a walnut. The left eye was markedly proptosed, and directed downwards and forwards. The lids were pinkish and slightly swollen, but the extensively visible sclerotic was quite white. The lateral movements were much limited, and the upward movement was entirely wanting. The pupil was active to light and accommodation; its indirect reflex action was perfect. The optic disc was diffusely swollen and ill-defined. The veins were very large, dark, and tortuous. The vision on this side appeared good. The other eye seemed to see properly; its fundus was quite normal. The child was very irritable, constantly calling out "Oh! my eye!" if examined, or even moved for any purpose whatever. On October 4th, at 6 A.M., she was convulsed for forty minutes. On the 11th the liver was apparently more distinctly nodular. The breathing was irregular, with a great many râles and rhonchi. On the 13th, at 9.30 A.M., she was convulsed for over two hours. The convulsions began on the left side, though the movements were shortly transferred to the opposite side. Then the right hand was clenched, and there was a continuous jerking movement backwards of the hand and arm. The right leg was slightly convulsed. The right eye was turned to the left, and its pupil was widely dilated. The left eye was much congested, and protruded and jerked slightly. The breathing was jerky and

noisy, with a good deal of froth about the mouth. The temperature rose from normal at the commencement of the convulsion till 3 P.M., when it was 104·2°. Death occurred about twelve hours later. At the post-mortem examination a cyst the size of a large walnut was found in the upper part of the left orbit, and its pressure had displaced the eye forwards and downwards. It was actually within the superior rectus muscle of the eye, implicating it from near its origin right up to its tendinous insertion; the muscular fibres were seen to expand as a thin sheet on the posterior part of the cyst, except on its lower and outer aspect, where they were scarcely traceable. Further forwards all trace of them was lost, except on the extreme inner side, where they were continued as an extremely attenuated layer right up to the tendinous insertion of the muscle. The much-enlarged liver showed numerous cysts, projecting as bosses, on its surface, most about the size of a pigeon's egg. Thirty-six could be counted without any dissection. The lungs contained about twenty large cysts, mainly in their lower and posterior parts. There were recent pleuritic adhesions at each base, but no fluid exudation. The spleen showed a very large cyst, nearly two inches in diameter, projecting from its upper part. The right kidney showed a somewhat smaller cyst, and one the size of a pea was found embedded in the left ovary. None were found in the peritoneum. On opening the cranial cavity, the dura mater was found closely adherent to its walls. A cyst, the size of a tangerine orange, was embedded in the posterior superior part of the right cerebrum, where it shelled out easily from beneath the unaffected pia mater. It occupied the region of the right angular gyrus and submarginal convolution. The cysts were those of the Tænia echinococcus.—Dr. HUGHLINGS JACKSON said that the case was one of great interest. He supposed that the left-sided optic neuritis was produced by the hydatid, which involved the right cerebral hemisphere and caused the left-sided fits. He had seen but three cases of uniocular neuritis, in which necropsies had been obtained, and in each the optic neuritis was in the side paralysed, both symptoms depending on tumour of the opposite cerebral hemisphere.—Mr. BULKE thought the concurrence of hydatids of the orbit with hydatids elsewhere was remarkable. In two cases—boys, aged fourteen and twelve—of hydatid of the orbit that he had seen, these were the only tumours.—Mr. NETTLESHIP asked whether there was any inflammation about the hydatids.—Dr. BRAILEY, in reply, said there was nothing unusual around the hydatid in the orbit; it actually replaced the superior rectus. He considered that the proptosis caused the neuritis, but deferred to the authority of Dr. Jackson.

Mr. EDGAR BROWNE read a paper on a case of supposed Quinine Amaurosis. The diagnosis in the earlier recorded cases of quinine amaurosis had been facilitated by a knowledge of the amount of the drug taken. In this case the quantity was not clearly ascertained. The patient was a powerful man, aged thirty-four; had syphilis in 1877; was carefully treated; was temperate; formerly a heavy smoker; general health perfect. Fell into the water at Shanghai on Jan. 3rd, 1886; had a rigor next day, followed by pneumonia. On Jan. 6th his temperature was 104°. Was told he was taking quinine to reduce his temperature. On Jan. 7th his temperature rose to 105°, or more. The patient believed the quinine was increased to thirty grains every two hours, but there was no professional note of this amount. Patient thought he had taken about 120 grains in this way. Towards afternoon he had a "confusion" in the ears, and became very deaf. About 4 P.M. there was a flickering before his eyes, and he suddenly went completely blind, "as if they had turned out the gas." He had a double perception of the difference between dark and tropical sunlight, but he could not perceive the flame of a candle a few inches from his eyes. The pupils were widely dilated. At the end of six weeks he began to see objects in bright sunlight, and his central vision rapidly returned. Slight paresis of internal rectus. No sign of syphilis, except a doubtful enlargement of posterior cervical glands. Patellar reflexes normal. Fields for white very contracted; greatest diameter nowhere beyond 20° from fixing-point. Optic discs very pale; vessels extremely small and contracted. Hearing perfect. From that time to Dec. 4th scarcely any change had taken place, except a slight failure in central vision of left eye. He could distinguish a light thrown from a short-focus mirror (as in testing the sensibility of the retina in cataract) up to the periphery. He was [illegible] in great difficulties by his telescopic vision and constantly ran against things. He was in remarkably good health, with no sign of cerebral or spinal mischief, except perhaps the slight paresis of the rectus. He had collected references to eighteen cases, including his own. The symptoms were blindness and deafness of a very marked character—deafness first in order of time, temporary in duration, and recovery rapid. In two cases twenty-four hours, one ten days, and in one some permanent impairment. The onset of the amaurosis was sudden or very rapid, more complete than was known in any other recoverable condition. It resembled the dense darkness of atrophy, for which one case was mistaken. In one case the deafness and blindness were so complete that communication was only possible by touch. In cases examined by the ophthalmoscope early, a whitish haze with a central cherry-coloured spot was observed at the macula, as in embolism. The retinal vessels were always extremely contracted. In one case the contraction was first noted on the eighth day of the blindness, the first examination being on the fourth. The optic discs were pale, pupils always widely dilated, and insensible to light. In one case accommodation-reflex (convergence) was present. Hence it might be inferred that the state of the pupil was due to the blindness, and not to affection of the third or sympathetic. The mobility of the pupils was restored. Duration of the blindness very remarkable. No perception of light existing for three or four days, six weeks, and even seven months. Recovery of central vision when it commenced was rapid. There was central colour-blindness in early convalescence. Out of eighteen cases, no contraction in four; contracted for colour, one; no notes, two; great contraction, eleven. In one case there was central scotomata, but it was not noted if the patient was a smoker. In some cases the field widened somewhat, but in pronounced cases it is never fully restored. The perceptive portion of the retina corresponded to the non-vascularised space around the macula, exactly the opposite condition as regards parts of the retina affected in axial neuritis, when there was central scotoma with peripheral perception. This pointed to a more decided demarcation of the central from peripheral retina than was usually described. Recovery of central vision was generally perfect; permanent blindness not having been recorded. The quantity of quinine taken ranged from 180 grains in a single dose, 100 grains per diem for four days, to 46 grains per diem for eight days in adults. The resemblance to embolism or hæmorrhage into the optic nerve was obvious, but the bilaterism and complete recovery of central vision negatived these. The retinal ischæmia seemed local; there were no signs of general cerebral anæmia. The influence of the vaso-motor system must be considered. The first effects of toxic doses of quinine were felt in the labyrinthine circulation. It was supposed that the inferior cervical ganglion was especially affected, and the condition was hyperæmic. It seemed unlikely that hyperæmia of the labyrinth should coexist with retinal anæmia from the same mechanism. The deafness was temporary, while the peripheral blindness was permanent. The affection was probably local. The occlusion of the arteries was not retro-ocular nor quite complete, or atrophy of the optic disc would be a probable sequence. There was no sign of periarteritis, nor was there any pressure, veins and arteries being alike attenuated. Quinine applied locally causes contraction of minute blood-vessels. Highly cinchonised blood, passing into a peripheral circulation unprovided with anastomoses, might deposit sufficiently to prevent the ingress of blood till such time as the contraction has become permanent. Information was needed on the appearances in the early stage of the amaurosis, whether the pupil reacted to myotics, what was the condition of the optic disc, and whether there was any fluorescence of media or retina.

SOCIETY OF MEDICAL MEN QUALIFIED IN SANITARY SCIENCE.—At a meeting of the members of this Society on the 14th inst., it was reported that the Council had been in constant communication with the various medical corporations, the universities, and the General Medical Council, with a view of procuring a similarity in the nomenclature of the title of diplomas in sanitary science, and had strongly recommended that "Diploma in Public Health" be the style adopted for registration. Dr. Alfred Carpenter gave an address on "The Duty of the State to foster the Cultivation of Sanitary Science." Sir J. Fayrer afterwards strongly supported [illegible] and Mr. J. F. Sykes read [illegible] as a Career."

Notices of Books.

A Text-book of Human Physiology, including Histology. By Dr. L. LANDOIS. Translated from the Fifth German Edition, with Additions, by W. STIRLING, M.D. Second Edition. Two Vols. London: Charles Griffin and Co.—This edition of Dr. Landois' work has been thoroughly revised, and many corrections and additions have been made by the translator. It is the only text-book of physiology with which we are acquainted in which the practical bearings of physiology on medicine and surgery have been constantly borne in mind both by the editor and translator. If the contents of this treatise were thoroughly mastered by the student during his first two years of study, he would enter the wards of his hospital fully competent to understand that disease is only a modification and perversion of normal processes, and not a separate entity to be expelled by certain drugs. Dr. Stirling has added a chapter on the action of drugs, and the chapters on the nervous system have been considerably modified. A great improvement has been made in adding a very copious bibliography, which refers the student to the principal sources of the information contained in each chapter. The number of the woodcuts has been augmented by nearly 100 figures.

Commercial Organic Analysis. A Treatise on the Properties, Modes of Assaying, and proximate Analytical Examination of the various Organic Chemicals and Products employed in the Arts, Manufactures, Medicine, &c. By ALFRED H. ALLEN, F.I.C., F.C.S., Public Analyst for the West Riding of Yorkshire, &c. Second Edition, Revised and Enlarged. Vol. II.: Fixed Oils and Fats, Hydrocarbons, Phenols, &c. London: J. and A. Churchill. 1886.—Mr. Allen's book supplies a great want, and has been used with gratitude in every well-appointed laboratory. His new edition, of which this is the second out of three promised volumes, has been prepared with great care and enormous labour. One-half of the present volume is devoted to the fixed oils and fats; the other to hydrocarbons and allied bodies, including the terpines and benzene. The author has wisely refrained from discussing the coal-tar industry as a whole, although he has given much valuable matter in regard to it. He may, perhaps, give us a separate volume upon it, and we hope he will, for he has a great power of lucid writing and arranging; but he could not have done justice to the subject in a small space. What he has attempted he has attained and those portions of his work which are before us are crowded with information often original and always well compiled, with full and fair references to original authorities. We may point to the sections on soap, in which the recent work of Dr. Alder Wright and others is summarised, as a good example of his style.

The Chemistry of Wheat, Flour, and Bread, and Technology of Bread-making. By WILLIAM JAGO, F.C.S., F.I.C., Analytical and Consulting Chemist, Head Master of the Science Schools, Brighton. Brighton: Published by Wm. Jago. 1886.—This is a useful, and, as far as we have tested, a trustworthy, scientific, and practical treatise on the industry of wheat, with a fairly complete account of existing knowledge and practice, and some original matter. The first five chapters are occupied with general principles and elementary facts, partly chemical, partly physical. This part seems good, but we doubt the wisdom of inserting an elementary text-book in a special manual such as this; there are plenty of well-known and very cheap works which give all the necessary information. Then follows a more detailed study, accompanied with directions for experimental work, of the constitution of wheat and flour, the carbohydrates and albuminoids (this last chapter [illegible] and a good account of ferm[illegible] able, and show much original work. The sorting, so to speak, of yeasts by the microscope has of late years been recognised as a matter of the utmost practical importance. Full directions are here given, not only for this examination, but for the valuation of yeast by quantitative methods. The succeeding chapters are mainly devoted to the technology of flour and bread, while the rest of the book is mainly analytical, with a concluding chapter on adulteration, which is much too short. In the sixteenth chapter a good account of the viscometer and its indications is given. This instrument is employed for ascertaining the stiffness and tenacity of dough, and is said to be a valuable help to millers and bakers.

Sketch-book for Ophthalmological Observations of the Fundus of the Eye. By Dr. O. HAAB. London: Trübner and Co.; Zurich: Hofer and Burger. 1886.—This is a very handy and useful little book. It easily slips into the breast-pocket, and consists of a series of plates representing the fundus of the eye in vermilion with the optic disc. Some have, some have not, the retinal vessels. To enable the observer to insert the vessels a pencil is provided, with a bright red for the arteries and a dark red for the veins. The pencil has a cap with a piece of indiarubber attached, with which it is easy to expunge part of the vermilion of the plates, and in this way with the utmost rapidity an even inexperienced draughtsman can make a fair drawing of the eye when affected with choroiditis or hæmorrhages or with retained sheath. Every ophthalmologist should have one of these convenient little books in his possession.

Social Arrows. By Lord BRABAZON. London: Longmans, Green, and Co.—It will not be denied that the prosperity of a nation depends largely on the national care of the physical well-being of women and children. Lord Brabazon draws attention to the fact that unless some speedy change is made in the social condition of some of our women and children, the nation must inevitably deteriorate in the next generation. The utter absence in many large towns of adequate public playgrounds is a serious evil, as it is impossible for children to develop into healthy men and women without sufficient air and exercise. A public playground has been opened in Horsemonger-lane, and some also in Manchester and Salford. It has been found by the Metropolitan Public Garden Association that a playground can be daily provided for 3000 children at a cost of £100 a year. Horsemonger-lane playground contains a gymnasium, swings, running-ground, giant stride, fives court, and many other advantages. After 6.30 P.M., the young men of the neighbourhood are allowed to enter the boys' enclosure, and the young women that of the girls. There can be no question of the inestimable boon thus conferred on thousands of our poorer fellow-creatures, and the advantage to the national welfare will be great in its influence on the health of the people. Many efforts have been made of late years to shorten the hours of labour for various classes, but there still remains a class for whom legislation is necessary. Lord Brabazon states that girls in shops and refreshment-rooms are kept standing for an unpardonable length of time. In places of public refreshment girls work alternate days fifteen and eighteen hours, with but a very short interval for food. Many of the shop girls also work for fourteen hours. The effects of these long hours are most injurious in every way. That it is physically injurious it scarcely seems necessary to remark, and it appears also to be so morally. Many return home broken in health, and there are numberless sad tales of insanity, phthisis, bronchial affections, chronic dyspepsia, and other maladies. It must be said that many of the shopkeepers would willingly abridge the hours could it be made [illegible] all shops to close earlier. It is impossible [illegible] one [illegible] two points in this most interesting [illegible] Brabazon

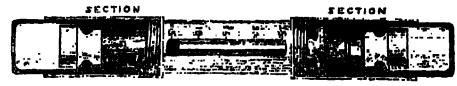
does not confine himself to the subject of women and children; he takes up the question of State-directed emigration, cultivation of flowers, young men's clubs, and many other things. The book is written throughout in a clear, sensible, temperate manner, and is well worth reading.

The Techno-Chemical Receipt-book. Containing several thousand Receipts covering the latest, most important, and most useful discoveries in Chemical Technology, and their practical application in the Arts and the Industries. Edited chiefly from the German, with additions, by W. T. BRAUNT and W. H. WAHL. Philadelphia: Henry Carey, Baird, and Co. London: Sampson Low and Co. 1886.—Although there are several good English technological receipt-books, and although they are not of primary importance to members of the medical profession, we notice this little book, first, because it is good of its kind, and likely to be useful in the thousand and one non-medical difficulties about which the "doctor"—often the only scientific authority in a district—is consulted; and, secondly, for the unpatriotic reason that it is "chiefly from the German." Whether the Germans are or are not superior to us in technical skill, all Englishmen will gladly acknowledge that they are skilful and industrious, and will be grateful to any compiler who collects in the English language the results of their labours. Five hundred closely-printed pages, well filled with useful matter, with alphabetical arrangement, a good index, and a table of contents almost as full as the index, make up a book which will be valuable in every house.

Brain. A Journal of Neurology. Part XXXV., October, 1886. London: Macmillan and Co.—The number opens with two papers of a controversial kind. Professor Schiff, aroused by Professor Horsley's strictures upon his experiments on Cerebro-spinal Physiology, gives a reply thereto, and hints that his opponent has not made himself sufficiently acquainted with the details of those experiments. Schiff, as is well known, is opposed to the commonly accepted doctrine of the motor functions of the brain cortex; and, moreover, believes that the posterior spinal columns are directly related to the excitable area in question. Professor Horsley follows with a spirited rejoinder, in which he demonstrates not only his full acquaintance with Schiff's work, but the fallacies that underlie his conclusions. Dr. Parinaud of Paris contributes a paper on Paralysis of the Movement of Convergence of the Eyes, and Dr. Sherrington one upon Two newly-described Tracts in the Spinal Cord—viz., the ascending antero-lateral tract (of Gowers and Hadden) and a tract of small fibres described by Lissauer at the junction of the lateral and posterior columns. Dr. Sherrington proves by developmental studies the independence of these tracts. Mr. Bland Sutton has a readable paper on the Lateral Recesses of the Fourth Ventricle, and their relation to certain Cysts and Tumours of the Cerebellum and to Occipital Meningocele. Mr. Birt raises the important but difficult question of changes in the urine due to nerve-metabolism in a paper on Urinology of the Insane. Dr. James Anderson gives notes of an interesting case of Tumour at the Base of the Brain, with a valuable commentary; and Dr. Hale White supplies a "critical digest" on recent advances in knowledge of Tabes Dorsalis.

Manuel Pratique de Bactériologie. Par EDGAR M. CROOKSHANK. Traduit par M. BERGEAUD. Ouvrage orné de 32 planches et de 44 gravures sur bois. Paris: George Carré. Bruxelles: A. Manceaux. 1886.—This is a literal translation of Mr. Crookshank's well-known treatise, and it speaks much in favour of the original work that the translator has not found it necessary to add any notes or observations. As far as we have compared the translation with the original, it appears to have been executed with care and fidelity. The plates are as good as those in Mr. Crookshank's work, which are, perhaps, a little too highly coloured.

The Physician's and Surgeon's Visiting List, Diary, Almanack, and Book of Engagements for 1887. Forty-first year. London: John Smith and Co., Medical Stationers.—We can cordially recommend this established Visiting List to our readers. The spaces attributed to the daily journal and the visiting list are convenient, and the tables and lists of drugs in the new Pharmacopœia and of American eclectic drugs, with the proper doses, make it very useful. Under the head of Baths, some instructions for cold baths in case of pyrexia should be included. The members of the councils of the principal medical corporations and of the General Medical Council should be given. But there is little to desiderate and much to praise in Smith's Visiting List.



Parkins and Gotto's Monthly Pocket Diaries present a feature which appears of a novel kind. There is a part for each month and a page for each day in the year, so giving plenty of room for entering a number of engagements, and only necessitating the carrying of one or two of the parts at most, which may be easily slipped into a letter-case.

CHRISTMAS LITERATURE.—*The Land of Little People* (Poems by FREDERIC E. WEATHERLY; pictures by JANE M. DEALY—London: Hildesheimer and Faulkner)—is a very pretty little Christmas book for the entertainment of the young folks during the approaching festive season. Both text and illustrations are of undoubted merit, and do credit to poet and artist. The same firm publish *Christmas Cards* of great variety, and some of them of remarkable excellence. —The Christmas Numbers of the *Graphic* and *Life* have been received. The former will no doubt be in great demand, as it is fully equal to, if it does not even surpass, any of its rivals.

New Inventions.

PORTABLE HYPODERMIC SYRINGE.

THIS portable hypodermic syringe is made entirely of metal, resembling an ordinary pencil-case, and may at all

times be conveniently carried in the pocket. The small glass bottles hold one fluid drachm, and are made to be withdrawn from the metal casing so as to facilitate their being filled. The needle is screwed in the piston-rod. The instrument in its entire length is 4½ in., and may be obtained from Messrs Krohne and Sesemann, Duke-street, London, W.

A. HERBERT BUTCHER,
Surgeon, Birkenhead Borough Hospital.

TESTIMONIAL.—The inhabitants of the mining districts of Carrizal Alto, Carrizal Bajo, and Cerro Blanco, Chili, have recently subscribed a sum of £200 to purchase a testimonial to be presented to Dr. William M. Johnson, who has served during the past ten years as medical officer to the Carrizal Hospital, and has attended the different mining establishments in the districts. During his long residence he has gained the love and esteem of all, both Europeans and natives, by his skilful treatment and his exceptional philanthropy. The proceeds of the sum subscribed have been sent to England to be devoted to the purchase of a valuable case of instruments, a gold watch chronograph, and a massive salver of pure gold, bearing [illegible] and remembrance

THE LANCET.

LONDON: SATURDAY, DECEMBER 18, 1886.

To say that we are disappointed with the circular just issued by the Council to the Fellows of the College respecting the admission of Members of the College to vote at the election of the Council, and to be themselves eligible to sit on the Council, would be a very inadequate expression of the feelings which possessed us on reading that document. These feelings are evidently similar to those which prompted "Historicus" to lose no time in issuing his note of warning and remonstrance. Were it not for an experience of the Council extending over more than fifty years, we should have thought that there had been inadvertence in framing the questions which have been submitted to the Fellows. But looking back to the times just antecedent to the granting of the Charter in 1843, when the "new class of members" was instituted, to the arguments then used, and to the tactics adopted, we cannot avoid the conclusion that the present Council (like the old one) are deliberately throwing dust in the eyes of the constituency, with a view to the maintenance of their own monopolies, to a continuation of the *status quo*, or to making the very least concessions with which the Council may satisfy the favoured few who have at present some feeble voice in College concerns. As issued, the circular implies that the Council are anxious to enlarge the privileges of the Fellows—to enable them to vote by voting-papers, without personal attendance at the College, while in reality very heavy pressure has had to be brought to bear before even this scanty concession could be wrung from them, although forty years have passed during which London has practically enjoyed this monopoly, as flagrant as it is unjust. Moreover, in seeking the opinion of the Fellows as to whether Members of the College should sit on and vote for members of, the Council, the restrictions which the Members themselves would impose are omitted; thus leaving it to appear as if Members were asking for identical privileges with the Fellows. Now the omission from the questions put to the Fellows of these restrictions is undoubtedly calculated to pervert the answers which will be returned. Such tactics on the part of the administrators of a public institution are altogether unworthy, and deserve the severest condemnation. The Fellows, we hope, will not so far lend themselves to this device as to give simple answers, Yes or No. We trust they will amplify the questions for themselves, or adopt as answers the resolutions passed at the general meeting on Nov. 4th.

Those resolutions were in effect as follows:—It is desirable that Members of the College should be empowered to vote in the election of the Council, and be eligible to sit on the Council, provided that, in order to be eligible to sit on the Council, a Member must have at least twenty years' standing; to vote at the election of councillors a Member must have, say, ten years' [illegible] and in order to give the Fellows a due [illegible] more than [illegible] of Members of the College. Let Fellows, before returning their circulars to the College, compare and contrast the foregoing proposals as they emanate from the Members with the unconditioned questions as propounded by the Council. What a difference! The one guarded by wise restrictions; the other bare, unqualified, and misleading: in fact, a totally new issue. Let those who have not yet read Mr. HOLMES' speech at the meeting on Nov. 4th carefully do so. They will then see what it is the Members wish for, and the arguments that may be legitimately put forward in support of their contention. In issuing so bald a statement, the Council have laid themselves open to a charge of desiring to mislead the Fellows, to get their opinion on an issue not properly before them. Whether Members of the College of Surgeons shall vote is not the whole question. Holding as we do that a return of the original idea of membership—a brotherhood—will raise the professional status of each man individually, and of the whole corporation as such, and that it will conduce to the better management of the College, the question is a much wider one than it at first sight appears, and one which affects the general public as well as the State.

It is pretty clear to us that, whichever way the vote may go, the Members will have to look after themselves. Every inch of ground will have to be fought—and that, too, with a silent, self-satisfied Council. We should think that early in the new year the petition to Her Majesty ought to be presented praying for a new Charter. The Jubilee year will be a most propitious epoch to seek for such a boon—a Jubilee Charter of emancipation, restoring the rights of membership to those who have so long been strangers and outcasts in their own house!

IN February of this year the Liverpool Medical Institution appointed a Committee to inquire into the frequency with which abdominal section was performed, and more especially for spaying, or the "removal of the uterine appendages," at the Hospital for Women. The Committee consisted of the President of the Institution, three past Presidents, a Vice-President, and three past Vice-Presidents. The medical officers of the Hospital for Women were invited to send each a representative to the Committee; two availed themselves of the offer and one did not. The mode of conducting the inquiry was fair and reasonable, was calculated to do full justice to the medical officers, and at the same time to bring out the facts bearing on the subject of inquiry. The lay Committee of the Hospital for Women facilitated the work of the Committee of Inquiry. Each one of the medical officers of the hospital was asked to furnish reports of all the cases of abdominal section performed by him in the hospital. These reports were submitted to, and annotated by, the medical board of the hospital, and subsequently laid before the Committee of Inquiry. The medical practitioners of Liverpool who had cases under their care which had been operated on in the hospital were invited [illegible] information respecting the progress of the [illegible] operation; and between forty and fifty of [illegible] been made the subjects of abd[illegible] visited by the Committee [illegible] register of the [illegible] and nurses.

The following conclusions were arrived at: That the cases submitted to "ovariotomy" were fit and proper, and that the operation was done successfully; that the operations for "exploratory incision" were justifiable; that the operations for "oöphorrhaphy or the replacement and fixation of prolapsed ovaries" were insufficient in number to enable the Committee to form a strong opinion for or against the proceeding, but that the relief afforded by the operation was by no means clear and decided; that sufficient care and discrimination had not been exercised in the selection of cases for spaying, and that in many instances the gravity of the symptoms was not such as to have justified abdominal section of any kind; that in ordinary cases of pelvic hæmatocele spaying is not to be recommended; that the reports of the cases in which spaying was performed for "bleeding myoma" "signally fail in giving any description of the size and character of the myomata, or of the state of the uterus when the abdomen was opened at the time of the operation"; and that certain patients were reported as cured when the patients themselves stated that they still suffered from hæmorrhage. The Committee further finds that of ninety-two patients submitted to the operation of spaying, fifty-nine were between twenty and thirty years of age, and seven were only between seventeen and twenty years; that a considerable proportion of the subjects of it suffered a distinct loss of sexual feeling, and to such an extent as to cause serious domestic unhappiness in not a few instances; and that some of the patients complained of such a loss of physical energy and spirit as prevented them from discharging their ordinary household or other duties as they did before the operation. Many of the patients suffered from hernia in consequence of the operation. Many were distinctly and probably permanently benefited, while nearly an equal number experienced no decided and lasting benefit, while in some the operation proved injurious. The Committee finally recommends that no patient should be spayed by any officer without consultation with a colleague and that the patients should be clearly informed of the nature of the operation and its possible consequences; for the Committee say that the patients examined by them very generally denied that sufficient information—or, indeed, any information at all—was given them respecting what was proposed to be done to them.

The report of this Committee is calculated to do much good by throwing light upon the indiscriminate way in which spaying is had recourse to, and upon the results of cures effected by it. We have frequently pointed out these facts, and again and again stated that recovery from the operation is not a cure of the patient. It comes out clearly in the report that patients are spayed in cases in which it is not calculated to give relief, for about the half of those who were operated on obtained no decided or lasting benefit. The report is calculated to check indiscriminate spaying and to confine the operation to the few cases in which it is really indicated.

WORKHOUSES usually escape the keen criticism and amateur inspection that modern philanthropy bestows on the working of most institutions set apart for the benefit of the poor, and which, when properly conducted, provide a useful and efficient check on abuses. Workhouse visiting is not popular among ladies, and the consequence is that very little is known to the outside world of what takes place inside these institutions, so that when some scandal occurs blame is too often laid on the wrong shoulders. We ought, therefore, to be grateful to anyone who, having been behind the scenes and having become acquainted with details of workhouse life, gives us an impartial account of the state of affairs, and who also suggests practical remedies for existing evils. And this was done, and well done, by Miss LOUISA TWINING, in the last number of the *Nineteenth Century*. Miss TWINING admits that great improvements have taken place within the last thirty years, since THE LANCET, with the aid of its Special Commission, of which the late Dr. ANSTIE was the head, exposed the horrors of the London Workhouse Infirmaries, an exposure which resulted in the movement that ultimately led to the passing of the "Gathorne Hardy Act," which brought about the amalgamation of several unions to found the noble sick asylums now distributed over the metropolis. Nevertheless, from time to time, in spite of improved regulations, instances of gross cruelty become public which lead us to doubt whether, after all, the improvement is more than what appears on the surface. So long as aged and infirm paupers continue to be scalded to death in hot baths, or epileptics and imbeciles to be roasted or beaten to death by their imbecile attendants, we must feel that, in spite of the good intentions of the Poor-law Board, guardians do not always obey the wholesome provisions laid down for their guidance, and that workhouses in this country are sometimes the scenes of abominable neglect, if not of direct cruelty.

And, again, there are cruelties that never come to light. The class from which the workhouse officials are drawn is certainly not one to which much power ought to be given. Dealing with an admittedly refractory and troublesome race, the callousness which the administraton of an iron discipline engenders often tends to convert these officials into petty tyrants rather than intelligent administrators of State charity. We will give one instance only, which has come under our notice, and which occurred in one of our admittedly best-managed workhouses. A poor woman, aged seventy, who for years had kept a small lodging-house till her husband died, had a stroke of paralysis, and, being no longer able to work, went into the workhouse. She begged hard to be allowed to retain her under flannel petticoat, which had been given her by a charitable lady, but to no purpose. It was taken from her, and she had to wear the ordinary thin garments served out by the authorities. Now, the deprivation in this case was decidedly an act of uncalled-for tyranny, for although uniformity in dress may be one of the laws of the workhouse, still the authorities in special circumstances can order additional garments for the conspicuously infirm. In this case the leg that was paralysed, owing to deficient circulation in it, was subject to severe sciatic pains in cold weather. So this poor woman was condemned to suffer every winter to satisfy the master's or matron's love of uniformity, for if she is allowed her petticoat, "all the old women in the ward will be clamouring for one too!" Besides such acts of indirect cruelty, there is sufficient evidence to show that drunken[illegible] are, especially in [illegible]orkhouse

officials than is generally supposed; whilst the supposition that anything is good enough for the pauper leads to negligence among the officials in the selection and preparation of the food, of which, of late, numerous complaints (mouldy bread, carbolised broth, &c.) have appeared in the daily press.

Miss TWINING proclaims the urgent need for a higher class of workhouse officials, and points out that the posts are worthy of the intelligence, love, and zeal of the many educated men and women who are now seeking remunerative work, and who will find in the administration of these large institutions an occupation worthy of their best energies. Miss TWINING is equally strong in advocating the admission of students of medicine into Poor-law infirmaries, a point our Commissioners insisted on in their Report on Workhouse Infirmaries in 1880. When it is considered that 600 or even a larger number of patients are often under the care of only two medical officers, it cannot be but that many of the minor attentions which add so much to the comfort of the sick must be dispensed with, whilst with such an inadequate medical staff the due supervision of the nursing becomes a difficulty. Lastly, a cruelty of the worst kind is in constant operation in the promiscuous mixing of all classes of paupers in common wards. The present system calls loudly for revision and alteration, for what can be more painful than for respectable men and women to find themselves thrust into the society of sturdy ruffians who make use of the workhouse as a convenient hotel, and who, being able to take their discharge with twenty-four hours' notice, can claim readmission whenever it suits them, whether drunk or sober.

INQUESTS and police-courts afford from time to time abundant evidence not only of the unsatisfactory condition of the law governing the burial of still-born children, but also of general ignorance of the law as it exists at present, and of consequent neglect of its enactments. The burial of still-born children is regulated by the 18th Section of the Births and Deaths Registration Act of 1874, which enacts that no person "who has control over or ordinarily buries bodies in any burial-ground" may permit the burial of the body of any deceased child as if it were still-born, or may permit the burial of any still-born child except on the production of one or other of certain certificates. To render legal the burial of a still-born child in any burial-ground there must be produced to the sexton: (1) a written certificate purporting that the child was not born alive, signed by a registered medical practitioner who was in attendance at the birth, or who has examined the body of such child; or (2) a declaration signed by some person who, had the child been born alive, would have been legally qualified by the Registration Act to give information concerning the birth, to the effect that no registered medical practitioner was present at the birth, or that his certificate cannot be obtained, and that the child was not born alive; or (3) an order of the coroner in case an inquest has been held. It is further enacted that anyone acting in contravention of this section is liable to a penalty not exceeding ten pounds. Such being the legal enactments on the subject, it follows that a certificate of still-birth [illegible] declaration of still-birth may be given by the father or the mother of the child, by the occupier of the house in which the child was born, or by any person who was present at the birth of the child—these being the persons who would have been legal informants of the birth for registration purposes had the child been born alive. It is patent that declarations of still-birth may in certain cases be produced with dangerous facility—more especially bearing in mind that these declarations pass direct from the hands of the person whose interest it is to get the body buried, into the hands of the person whose interest it is to effect as many of such burials as possible. The Registration Act, moreover, omits to schedule the forms of these certificates and declarations, and it is useless to expect the ordinary sexton of a burial-ground to be an efficient judge of the legality of such documents as are produced to him in justification of his right to bury still-born children. There seems to be no sufficient reason why these forms should not be supplied by the Registrar-General through his local registrars, and that the use of such recognised forms should be insisted upon by the Home Office. It would, moreover, afford a greater security against malpractices if the certificates and declarations were furnished to the local registrar, who, if they duly complied with the law, should issue an order for burial. The use of such authorised forms might also be made the means of supplying information as to the number of still-births in England, of which no record now exists, and in which respect our vital statistics are inferior to those of almost every other country in Europe.

A recent inquest case in Yorkshire accentuates the necessity for the dissemination of more accurate knowledge of the present state of the law on this subject, even among those whose especial duty it is to inform themselves thereof. The sexton admitted having buried several so-called "still-born" children without the production of any certificate or declaration of still-birth; and in the case which was the subject of the inquest referred to, the declaration was entirely informal. This declaration was informal because it was signed by a woman who was not present at the birth and would not, therefore, have been a qualified informant of the birth had the child been born alive; and, secondly, because it did not state that no registered medical practitioner was present at the birth, or that his certificate could not be obtained. The coroner, moreover, although fully alive to the dangerous tendencies of the facilities which now exist for burying deceased children as still-born, appears to have been but partially informed as to the actual state of the law on the subject. We hope, however, that other coroners will follow his example by holding inquests in all such cases in which laxity prevails with regard to the burial of still-born children.

AT a meeting of the Council of University College, Dundee, held on the 12th inst., a letter was read from Mr. T. H. *Cox*, offering a donation of £12,000 for the endowment and equipment of a chair of Anatomy in connexion with the College. Mr. Cox, in his letter, states that the people of Dundee should now shew they have taken up seriously the proposal to establish a medical school in the town. He adds that he wishes this donation to be received as his gift to Dundee to commemorate [illegible] Jubilee. The Council [illegible] thanked Mr. Cox for [illegible]

Annotations.

"Ne quid nimis."

THE TEACHING UNIVERSITY FOR LONDON.

THE meeting held at King's College on the 15th inst. for promoting the movement in favour of a Teaching University was very sparsely attended, only thirty or forty out of the 400 members of the Association being present. From the report which was presented and the speeches that were made, it would seem that the professoriate and councils of King's and University Colleges were mostly in favour of the scheme, and that it had the support of many London physicians and surgeons, Guy's Hospital being especially mentioned. Very little encouragement is anticipated from the University of London, although a final reply has not yet been obtained from the Senate. The Colleges of Physicians and Surgeons have merely acknowledged the receipt of a communication proposing a conference, but have taken no action thereon. Power was granted by the members of the Association who were present at the meeting to the Executive Committee to "approach Her Majesty's Government for the purpose of obtaining from the Government and Legislature the necessary measures for forming a teaching university in London." It was clearly apparent that the Association, whilst not opposing the granting of a degree in medicine and surgery under the authorities of the combined Colleges, would use all its influence towards turning such a degree from a strictly professional into an academic one, and would strive to widen the basis of the collegiate movement, so as to secure, if possible, the admission of faculties of arts and science as well as of medicine. This might be successful, if we could really believe in the vigour and earnestness of purpose of the members as well as of the executive; but Wednesday's meeting makes us doubt whether, notwithstanding the lengthy reports and the conferences, there is any real interest taken in the movement by the teachers of arts and science, or even of medicine, in London.

PROMOTION IN THE ARMY MEDICAL SERVICE.

WHEN we lately brought under the notice of our readers the great want in the Army Medical Service of any acknowledgment of or reward for meritorious professional services, we did not anticipate that we should so soon have occasion to comment upon the very unsatisfactory results of the system now in operation. In a supplement to the *Gazette* of Nov. 26th, Surgeon-Major W. H. A. Mackinnon was promoted to the rank of brigade surgeon in recognition of his services in Burmah. He happened to be the senior medical officer with the British Force at Mandalay, and was in consequence selected for a reward. But his position as one of the most junior of the grade of surgeons-major ranking with lieutenant-colonels involved his superseding more than ninety officers senior to him in the Department, many of whom have done right good service without reward, and who would have been delighted to have had a chance of being employed on active service. In addition to the injustice done to so many officers by his promotion, there was another point of great importance involved in it. From his position on the list, it is doubtful whether he has been called upon to undergo the qualifying examination laid down in the Army Regulations as imperatively required to be passed before a surgeon-major is eligible for the post of brigade surgeon, and if so the promotion was contrary to the regulations of the service. Possibly from a consideration of these circumstances the *Gazette* of Dec. 14th intimates that "The promotion of Surgeon-Major W. H. A. Mackinnon to the rank of brigade surgeon, as stated in the *Gazette* of Nov. 26th, 1886, is cancelled, this officer having been granted the distinction of Companion of the Distinguished Service Order." We congratulate the medical officers senior to Mr. Mackinnon upon this reversal of an act of manifest injustice, and Mr. Mackinnon himself upon the acknowledgment of his services by an honorary reward. But the whole proceeding seems to us to raise an important question. By whom was the original mistake committed? Bearing in mind the history of the Army Medical Department, the difficulties it has experienced in getting a sufficient supply of eligible candidates to fill its ranks, and the care with which the present regulations were drawn up with a view to promote efficiency and allay discontent, it is of the utmost importance that anything like injustice should be prevented. Drawing our conclusions from the statements which Sir T. Crawford has repeatedly made to the officers of his department of the principles upon which his selections for promotion are to be based, and from the sound judgment and fairness which have hitherto characterised his rule, we do not believe that the promotion was made on his recommendation, and on this point we think that the Secretary of State for War should institute an inquiry and take steps to prevent the possibility of a similar mistake. It seems most desirable that in all cases the recommendation for a reward for meritorious service should emanate from the head of the department to which the officer belongs, and that all reports bearing upon the subject should be submitted to him for his consideration. In this way there would be a fair chance of valuable and meritorious professional work, which is now overlooked, being rewarded, and of injustice to the other officers being prevented. At present rewards to medical officers are apparently dependent, in most instances, upon the recommendation of general officers commanding; but it may be fairly assumed, without any disparagement to them, that they are scarcely fit judges of the value of professional work or of the manner in which it is done; it requires the knowledge of an expert to appreciate it at its true value. And yet it is of far more importance to the well-being of the soldier than the quasi-military duty for which, under the existing system, the rewards and decorations are bestowed. Hitherto it has been too much the practice of the military authorities to over-rule recommendations of the Director-General for the reward of professional work, and the case now under notice shows how rewards may be conferred contrary to the principles of justice and in defiance of the regulations of the service. We believe the existing system only requires to be brought under the notice of Mr. W. H. Smith to undergo a much-needed and judicious modification.

TYPHOID EPIDEMIC IN YORK.

A CONSIDERABLE epidemic of typhoid fever is prevailing in York. Towards the end of September cases of this disease rapidly augmented in number, the largest increase taking place in October. The disease was maintained throughout November, and in the three months ending Dec. 4th there had been 185 cases. Mr. North, the medical officer of health has the matter under consideration; and he has already made a number of inquiries which lead him to conclude that the epidemic is mainly due to contaminated milk. Indeed, he says that there are very few places near York from which milk can be safely distributed if typhoid fever existed on the premises. This, unfortunately, whilst explaining how the distribution of the disease has, in great part, been effected, by no means gets over the difficulty as to the origin of the infection and the process by which it got into the dairy or dairies affected; neither does milk-distribution account for more than a [illegible] in 1884 no less than [illegible] fever, and

that about fifty of these, or one in six, died. The outbreak was carefully investigated and reported on both by Mr. North and Dr. Airy of the Local Government Board, and advice was given to the sanitary authority as to such matters as the strict supervision of milk-supplies, the systematic removal by the corporation of night-soil and refuse, and the ventilation and flushing of the sewers. We shall look with interest to Mr. North's forthcoming report to see what progress has been made in these matters. In 1884 both Dr. Airy and Mr. North seemed convinced that the water-supply did not cause the epidemic, although it is drawn from the Ouse at a point below which it and its tributaries receive the sewage of a number of towns and villages. And, in the present instance, Mr. North provisionally expresses the opinion that the consumption of this river water is not the cause of the epidemic. This may be so, but the arguments with which this view is backed by some persons are not altogether satisfactory. Thus it is stated that 75,000 people drink this water, and that if the supply had been in fault the epidemic would have been more extensive. We agree that the epidemic as a whole does not support the view of a single cause in the form of water. But the typhoid poison must be regarded as particulate, and its occasional presence in the river as it passes the pumping-station might produce very different results from those following on the existence of the same infection in a well. In short, such a river-supply could easily initiate an epidemic, which would afterwards be spread by milk, sewers, and privies. It is locally suggested that chemical analysis of the water should be made. We have no objection, except in so far as any judgment as to the absence of a particulate infection from a given sample of an ever-varying supply may be formed from the negative results of the chemist. Chemistry serves most valuable purposes in connexion with water analysis, especially in so far as positive results are concerned; but hitherto the chemist has failed to detect typhoid excreta even when deliberately added to the sample of water submitted to him, and it cannot be expected that he can judge of the absence of such means of infection as a cause of this long-continued epidemic from samples taken now, or even at an earlier date, from the river service.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE harmony and success of the annual meeting of the constituents of the Hospital Sunday Fund are a matter for sincere congratulation. Now, when a fierce criticism beats upon every institution, it is not to be wondered at that even hospitals for giving a temporary home to the sick, the lame, and the blind should have their critics. Many of these critics are perfectly honest in their criticism, and deserve to have their views well considered. The hospitals might add to their enormous and unequalled claims on the benevolent a yet further claim by co-operating with those who would eliminate all abuse from them, and help the development of those provident medical institutions which encourage the thrift of the people. This would tend to reserve the funds of the hospitals for cases of magnitude and misery, which in our population of four millions are still scantily provided for. One reason why the Hospital Sunday Fund enjoys the confidence of the public so much is that the Council contains many members who are deeply anxious to see hospitals do all the good they can and no harm at all, either to the poor or to the medical profession. The new members of the Council—to wit, the Rev. Prebendary Eyton, the Rev. C. J. Ridgway, the Rev. John Clifford, the Rev. J. R. Wood, the Right Hon. Earl Strafford, Sir Andrew Clark, Lionel Cohen, Esq., M.P., Alderman F. de Keyser, Richard Foster, Esq., and Thos. Wakley, Esq., F.R.C.S. Eng.,—will be a further guarantee to [illegible] be wisely [illegible] Council and the harmony of the constituents that the best promise lies of good work and large collections. The sum raised this year (£40,399), however, is in itself a very gratifying one, being £6000 more than in 1885, and £8000 more than the average of preceding years. Finally, we may heartily congratulate the Fund on the succession of another Lord Mayor in full sympathy with the cause of hospitals and of Hospital Sunday. Sunday, June 19th, is fixed for the collection of 1887.

ALCOHOL IN DISEASE.

OUR teetotal friends have had such a set of the tide in their favour of late years that they take badly any little sign in the opposite direction. They have seen medical and physiological authorities one after another admitting that alcohol was dispensable in a large number of diseases, and that for ordinary purposes of health those fare best who take it with extreme moderation. Great physicians have taken their brandy or even their sherry in *petits verres*, and have declared the inability of people with healthy organs to appropriate more than a very small quantity. More than this is discharged as at best useless and often injurious. All casual drinking, drinking at odd times and on empty stomachs, and for the mere sake of drinking, has been denounced as treason to the finest organs of the body, and fraught for the mass of the people with future and not remote mischief and trouble. Intelligent lay people of both sexes have been quietly dropping the habit of taking much alcohol, partly from moral considerations, but largely from the report of science as to its action, and largely too from the fact that their own sensations and experience concurred with the teachings of science. All this was surely enough to satisfy temperate abstainers. But there are intemperate teetotalers, as we have always said. They will allow no virtue in alcohol. It is evil, and only evil, and that continually and in all cases. They usurp the place of the physician, and dogmatise where doctors deliberate. The true friends of temperance should disown such advocates. They do immense harm; they exclude thousands from the great army that is available against excess, and they put into an attitude of opposition the medical profession, which has enormous power to help all true social and dietetic reform. Our own attitude in this matter is well known. We take the evidence of every witness who has common sense or special knowledge, and try to weigh it. Two witnesses are before us as we write. One (Dr. Collie, medical superintendent of the Eastern Hospitals), who has been courageous in advocating good wine, in proper quantities, in those hospitals. He has defined his views in a paper in the *Practitioner*, vol. xxxvii., No. 5. He admits that alcohol is not required in the mildest cases of fevers, nor in the severe if the patient be taking a sufficiency of food, nor generally in young adults of the well-to-do classes. These are great admissions for Dr. Collie to make; but in opposite circumstances he maintains it is more or less necessary, and we advise our readers to consider his opinions. Briefly, in the chief fevers, to which his authority applies, they are as follows: In *typhus*, alcohol is rarely required for children or adults under thirty; but after this age it is required, and often in considerable quantities. It may be dispensed with early in convalescence, as solid food can be taken as soon as the temperature falls. In *scarlet fever*, alcohol is not required, as a rule, at any period of the disease. But in very poor children in early convalescence, with abscesses or "scrawny neck, alcohol in the form of port wine is indicated. He considers port wine four to eight ounces, good for children of the age of from four to six. For procuring sleep it is [illegible]. In enteric fever the chief value [illegible] convalescence, where solid food

cannot safely be taken for from ten to fourteen days from the return to normal temperatures. Alcohol is contra-indicated in cases of hæmorrhage unless collapse has resulted. Burgundies and champagne of well-approved brands are, he thinks, the best forms. Let Dr. Collie's opinions be considered in their entirety, and before our teetotal friends reject them contemptuously, let them pass through six weeks of the diarrhœa and fever of typhoid. The Bishop of Manchester is the other witness. He declares that after two years' experience of total abstinence he broke down utterly. His medical man gave him the choice of giving up work or taking a *slight stimulus with his meals*. The result justified the prescription, and the Bishop, instead of being a total abstainer, is a member of the Church of England Temperance Society, discontinuing all but the measured and medical use of alcohol at meals. Those who exclude him as a fellow-worker would have excluded the Apostle Paul for his prescription to Timothy, forgetting his other great prescription to all men—to "live soberly, righteously, and godly."

THE SANITARY STATE OF WEST COWES.

WE are glad to note that the Local Board of West Cowes have engaged the services of Mr. James Lemon, M.Inst.C.E., with regard to their system of sewerage. Mr. Lemon's report fully confirms the complaints as to the serious defects in the existing system. He states that the present system drains by means of fourteen outfalls upon the foreshore at all states of the tide, the result being deposits of sewage and annoyance to the inhabitants. Then there are tide-locked sewers generating noxious gases in the streets, to the detriment of the health of those living in houses connected with them. Indeed, such culverts were only constructed to receive surface and rain water, and Mr. Lemon points out that a perfectly water-tight, self-cleansing, and well-ventilating system is needed. This is, indeed, what official and other reports have before indicated; and now that the advice comes from a skilled engineer of their own choice, it is to be hoped the Local Board will face the situation, and free their charming sea-side resort from the stigma now attaching to it. Mr. Lemon enters into details as to his scheme, and he says that if the local authority will carry it out, Cowes will be rendered one of the most attractive seaside places in the south of England, and that its trade and prosperity will be greatly increased.

JUDICIAL STATISTICS OF VACCINATION.

A LETTER from Mr. William Tebb appeared in *The Times* of Monday, calling attention to the large number of persons who, during the year ending Sept. 29th, 1885, have been prosecuted in England and Wales for non-compliance with the Vaccination Acts. It refers also to the so-called house-to-house census which has been conducted by an anti-vaccination society, and quotes these returns as evidence of the large number of persons who are opposed to vaccination. MR. TEBB urges the appointment of a Royal Commission of Inquiry, and speaks of this as an expedient now approved by the leading medical journals and by about a hundred Members of Parliament. If this record be correct, it is evidence of the extreme mischief which can be done by a small number of mistaken enthusiasts; it is no difficult matter to stir up feeling amongst the more ignorant of the population against any existing legislative measure, and especially when such law entails even a trifling inconvenience upon those who have to submit to its dictum. Dr. Buchanan, in the last report which he presented to the Local Government Board, clearly expressed the opinion of the profession with regard to the enforcement of vaccination: "To the physician who realises the powers of vaccination, and who knows the malignancy of the disease against which it protects, the notion of enforcing the acceptance of such a boon is distressful. But the distress is akin to that with which he himself has at times to force nourishment down the throat of a lunatic who is starving himself; and in the case of vaccination he sees that it is for the security of children otherwise helpless, not of the recalcitrant himself, that compulsion is wanted." With reference to a Royal Commission of Inquiry, we cannot for a moment see that it would serve any useful purpose. Vaccination is in no sense of the word on its trial; the accumulative evidence of past years points conclusively to the fact that, with an infinitesimal amount of risk, it affords protection against one of the most terrible diseases that has ever destroyed mankind. Certainly the advocates of vaccination have nothing to fear from such an inquiry, but it would entail considerable trouble and expense, and no case has been shown for its necessity; moreover, however clearly a Commission reported in its favour, the decision would have no influence upon those who decline to be convinced by the teachings of the past.

THE DENSITY OF THE TEETH AS INFLUENCED BY THE FOOD, ETC.

DR. W. D. MILLER of Berlin has recently communicated to the American Dental Society of Europe the results of his experiments upon dogs, to show the effect upon the teeth produced by the absence or presence of lime salts in the their food. Every dental surgeon knows that the hardness of the teeth may vary greatly in the same individuals at different periods; the most marked, although by no means the only cases, are those of pregnant women; and this cannot be explained solely on the ground that the secretions of the mouth are vitiated by reduced acid from gastric disturbance. There is undoubtedly an absolute softening of the whole tooth substance, due, probably, to the robbing of the teeth of the mother of their lime salts in order to build up the osseous system of the fœtus. Dr. Miller is endeavouring to show experimentally how far changes can be produced in teeth. His *modus operandi* is to extract a tooth from a healthy dog, and then to feed the animal upon food containing but little lime salts for three months; a second tooth being now removed, the food is changed to one containing an excess of salts. This is continued for four months, when a third tooth is extracted. From the results of chemical analysis, he finds that there is an appreciable loss of lime salts in the first stage, amounting in one case to more than 1 per cent., and during the second stages that the proportion of lime salts rises to normal. The number of experiments has not been sufficient to give absolutely conclusive results, and no microscopic examinations have been made. Dr. Miller himself points out that Zalesky and Hoppe-Seyler, in their similar researches, maintain that the bones are not only deficient in lime salts, but that there is an absolute rarefaction, so we should expect some similar change in the teeth. We should also like to hear of some experiments on pregnant animals.

TREATMENT OF WHOOPING-COUGH.

THE following method of disinfection of sleeping and dwelling apartments and clothes is recommended by M. Mohn in the treatment of whooping-cough. It is said to cure the cases immediately. The children are washed and clothed in clean articles of dress and removed to another part of the town. The bedroom and sitting-room or nursery are then hermetically sealed; all the bedding, playthings, and other articles that cannot be washed are exposed freely in the room, in which sulphur is burnt in the proportion of twenty-five grammes to the cubic metre of space. The room remains thus charged with sulphurous acid for five hours, and is then [illegible] the same day, and

BACKWARD DISLOCATION OF THE FINGERS UPON THE METACARPUS.

IN an article which appeared in the *Boston Medical and Surgical Journal*, and which has been reprinted in pamphlet form, Dr. E. O. Otis discusses the above-named question. The author has taken as his text two cases of dorsal dislocation of the first finger backwards, which were unsuccessfully treated by him, but which led him to consider the subject thoughtfully and investigate the literature. The fact that such difficulty was met with in two consecutive cases led him to the opinion that the obstacles to reduction present were not such as are generally recognised. He reviews the anatomy of the joint, mentions numerous experiments which have been made by M. Farabœuf, and some by himself and others, in the majority of which the glenoid or anterior ligament of the joint ruptured at its attachment to the metacarpal bone, when the phalanx was forcibly displaced backwards, and comes to the conclusion that in the majority of cases it is this ligament which is the obstacle to reduction. If the proper procedures be employed to bring the phalanx into position again, this torn ligament is no obstacle to reduction. But if improper manipulation be used, by first flexing the phalanx and then making traction upon it, the ligament becomes completely reversed, its palmar surface resting on the metacarpal bone, and the dislocation becomes "complex" and irreducible. The author quotes largely from Jalagnier on the subject (*Archives Générales de Médecine*, Feb. 1886), and mentions the treatment to be adopted under such circumstances. Firstly, an attempt by extreme dorsal flexion to get the base of the phalanx behind the torn ligament, and thus convert the condition into that of simple dislocation. Secondly, on the failure of this, subcutaneous division of the ligament as it lies on the head of the metacarpal bone, the puncture being made to the outer side of the tendon. This latter is stated by MM. Farabœuf and Jalagnier to be both simple and absolutely efficacious. Other views as to the cause of difficulty in reducing these dislocations are mentioned, as also other methods of treatment; but Dr. Otis is inclined to look upon this as the usual cause of the difficulty in reducing these dislocations.

INSANITARY HOUSES.

A CASE of some importance to landlords and tenants has been decided during the past week in the Court of Appeal. The plaintiff let an unfurnished house to the defendant through an agent, who verbally informed the defendant that it was in good sanitary condition and fit for habitation. Subsequently the defendant alleged that he discovered that the statement as to its condition was incorrect — that the drains, water-supply, and ventilation were dangerous and defective. He therefore left the house and declined to pay the rent. At the first trial, before Mr. Justice Smith without a jury, a decision was given that the house was in an insanitary condition, that the plaintiff's agent gave the warranty upon which the defendant relied, and that the defendant left the house "within a reasonable time." Judgment for the defendant was accordingly given as to a claim for rent, and also upon a counter-claim for damages. On appeal it was argued that the law which implies a warranty of fitness for human habitation in the case of furnished houses could not be strained to apply to unfurnished houses; but for the defendant it was pleaded that the warranty was a condition of the agreement of tenancy, and that a breach of that warranty entitled the tenant to void the contract. The court found that in this case there was a warranty given by the agent, and that this [illegible] the question o[illegible] and the appeal was dismissed. The statement of an agent as to the condition of houses may now be held to be a warranty, which enables tenants to recover damages from landlords if any misrepresentation is made. The result of this case will be doubtless good, for it will tend to check the habit adopted by many house-agents of making inexact statements as to the condition of premises they are desirous of letting.

A NEW LOCAL ANÆSTHETIC.

DRUMINE is the title of a new Australian local anæsthetic discovered and described by Dr. John Reid of Port Germein, South Australia. Euphorbia Drummondii is the species from the milky juice of which the alkaloid drumine was prepared. Cocaine is known to have a mixed action on sensory and motor nerves, and causes preliminary excitement; whilst drumine is said to have an almost purely sensory paralysing effect, and does not cause excitement. Experiments were made on cats and on the observer's tongue. It was injected into the legs of the former animals and caused general dulness, with marked impairment apparently of all forms of sensibility. Placed on the tongue, nostrils, and hand of the observer, the resulting anæsthesia was most marked. The alkaloid has no action on the pupil, and small doses given internally produce no constitutional effect. It has been employed successfully in subcutaneous injections for sciatica and sprains. The experimentation has so far been imperfect and incomplete. We hope soon to have a fuller account of this new alkaloid, and to be able to give further information thereon. The amount injected subcutaneously was four minims of a 4 per cent. solution. Dr. Reid anticipates a brilliant future for the drug in the domain of nervous and cerebral diseases.

COCAINE IN DENTAL SURGERY.

OUR Paris Correspondent mentions in his letter in our last issue that M. Georges Vian claims to have solved the problem of local anæsthesia in dental extractions by means of the injection of one grain of cocaine hydrochlorate. Now this method has been in use for some considerable time in this country, the first published account being by Mr. Hunt of Yeovil in the *Journal of the British Dental Association* in January last, and a large number of other dental surgeons have been making experiments in the same direction. Cocaine is a most valuable adjunct to the Dental Pharmacopœia, but we think that its qualities have been somewhat exaggerated. For the production of local anæsthesia in dental cases, the solution which gives the best results is undoubtedly that made at the time by dissolving one grain of the hydrochlorate in ten minims of water; where it is kept for any length of time, even if carbolic acid, salicylic, or perchloride of mercury be added, it loses its anæsthetic properties. All are agreed that painting the gums with a solution, of no matter what strength, is useless, for the gums, unlike the conjunctiva, do not absorb it, and also the mucus which coats them forms an efficient barrier. The results of injecting cocaine have not been by any means uniformly successful, and even its warmest advocates admit that patients often say that they experience some pain, though not so much as when no anæsthetic has been used. Its disadvantages are many. The prick of the needle (which, however, may be masked by painting the gum first with a solution of cocaine), the mental suspense of waiting from three to five minutes, and the consciousness of the operation being performed, are all attended with pain; but there is a much more serious aspect—the after-consequences. There are reported a large number of cases of syncope lasting for from ten minutes to an hour after its use. We know of no case where the "cocaine habit" has been formed after its

use in dental cases. In judging of the value of all local anæsthetics, the effect of imagination has to be eliminated; and we know of more than one case where patients have been told that they would feel no pain, and only water has been injected, yet they declared they felt nothing. In cases where the administration of nitrous oxide gas is objected to by the patient, or for other reasons not admissible, the injection of cocaine may be resorted to with advantage; but we do not think that it can ever compete with the gas. Apart from extractions, its use in dental surgery is manifold and great, in the treatment of exposed pulps, applications of the rubber dam where the gums are tender, lancing abscesses, and in many other circumstances.

THE NEW EXAMINATION BUILDINGS.

THE New Examination Hall on the Thames Embankment is rapidly nearing completion, and the question as to the uses to which the vacant plot of land not required for the building should be applied must soon be determined by the authorities of the combined Colleges. If pecuniary reasons are not urgent (and, considering the large incomes now derived by the two Colleges from their examinations, we should not suppose they could be), we would recommend that it should be left as it is, and should not be built on until the requirements of the examining board have been fully tested by one or two years' experience. It will then be time enough to decide whether class-rooms and laboratories for elementary or advanced scientific teaching and work could be added with the greater advantage. If, as is rumoured, there is a great divergence of opinion on this point, there is the more reason for delay, and for not taking any definite step which cannot be subsequently retraced if such a course should then seem expedient.

THE PROGRESS OF CHOLERA.

CHOLERA has again shown signs of activity, and its progress is further in the direction of eastern Europe. Several deaths from this disease are stated to have occurred in a village in the vicinity of Tirnova, in Bulgaria, the infection being alleged to have resulted from the importation of some clothing belonging to a man who had died of cholera in Hungary, where there have already been 966 cases and 499 deaths. The disease still lingers in certain parts of Hungary and Galicia, and if we have a recurrence of the epidemic next year, it is by no means improbable that it may take its start from some of the localities more recently infected in the Austro-Hungarian Empire. The east of Europe is probably much less prepared to withstand its progress than was the west.

CIRCULATION IN GANGLION CELLS.

PROFESSOR ADAMKIEWICZ of Cracow has recently published some observations on the circulation in ganglion cells, which, if confirmed, certainly adds to our knowledge of the physiology of nervous tissue. The ganglia chosen for observation were the intervertebral ganglia connected with the cords forming the brachial plexus. Carmine injections were made by means of the spinal arteries, and examination showed that each cell has a special arterial twig, which is distended so that its walls surround the ganglion cell, which consequently is situated in the lumen of the vessel, and is bathed completely by the arterial stream somewhat in the same way as the placental tufts are bathed by the blood in the maternal sinuses. This, however, is not all; for the cell itself contains a number of exceedingly minute vessels or passages from the circumference to the centre, which of course admit serum only; and this, which enters the cell in an arterial condition through numberless peripheral orifices, is collected at its centre as venous serum—forming, indeed, what has hitherto been looked upon as the cell nucleus, which therefore, instead of being solid, is liquid, or rather a cell containing liquid, the only solid part being the nucleolus. This venous serum is conveyed away by a single vessel or vein which runs into the general venous circulation. Besides all this, it appears that the whole bloodvessel apparatus of the ganglion cell is surrounded by special lymph vessels, so that the arrangement is highly complicated, and offers an interesting field for further research.

THE EDUCATION AND REGISTRATION OF ARCHITECTS.

IN a paper read before the Society of Architects on the 14th inst. by one of the Vice-Presidents, Mr. D. Howard Seth-Smith, is to be found the first outline publicly announced of the Bill which is proposed for "closing" the architectural profession—a step of great importance in many ways to the whole country, but especially from the standpoint of health. The leading provisions of the proposed Bill are (1) the establishment of a Council similar in objects and duties to the General Medical Council; (2) the payment of fees for registration, which are to go to defray the expenses of carrying the Act into execution; and (3) the regulation of qualifications for registration. At the present time, in the eye of the law everyone has an equal right to practise as an architect, and consequently every man who has fairly entered on practice has a right to a place on the register. Immediately, however, the Act comes into force the compulsory education of the entire profession will commence, and imperfectly qualified men will be stimulated to self-improvement by increasing competition, and will be gradually supplanted by a race of cultivated practitioners. The plumbers are registering themselves as competent under a severe test, and intend to apply for an Act of Parliament to render that test compulsory; and although it would perhaps have been more fitting for the architects to have led the way in such a step, that fact does not prevent us from congratulating them upon so promptly following the good example set them.

FARTHING DINNERS.

THE cheap dinner movement appears to have reached its climax in Birmingham, where a bowl of soup sufficient to satisfy some appetites at least, and capable of producing an evident nutritive result, is sold to poor school-children at the cost of one farthing. Full details respecting this new departure in dietetics are to be found in an interesting and practical paper on the subject by Mr. G. H. Sargant. The fact that any measure of real success can attend an outlay so trifling is significant. It amounts to proof, which ought to be convincing, that there are in this system principles and methods in diet which have long lacked application, but are most happily adapted to meet the requirements of almost any depth of poverty, in some degree at least. In looking through the history of the farthing dinner three noteworthy points present themselves. It is evident, in the first place, that a successful result depends greatly on the number of diners; 400 or 500 are more easily fed at this cost than 100. Secondly, it is not without reason taken as an axiom that the digestive function, like every other, is depressed by hunger, and that therefore the fittest food for a child in this condition consists of light vegetable or mixed diet well diluted with water to form a soup. In the third place, the highly nitrogenous leguminous products, such as peas and lentils, even when used as a scanty thickening for hot water, are shown to have a nutrient value which is distinctly recognisable. Look at the matter as we may, we cannot, of course, regard that children thus nourished are well as good practice

in the system, and when the wolf of hunger is at so many doors every form of succour is welcome. Those who, like ourselves, are interested in this question of the time will do well to read Mr. Sargant's paper, which abounds in shrewd and experimental suggestions.

PROPOSED TESTIMONIAL TO DR. ARCHIBALD H. JACOB.

IT has been suggested by many medical practitioners residing in Dublin, as well as in various parts of the country, that the present is a fitting time for the members of the medical profession throughout Ireland, and especially those holding public appointments, to present to Dr. Jacob a testimonial as a recognition of the esteem in which he is personally held, as well as of the important services he has for the past twenty years rendered for their benefit. As an active member of the Irish Medical Association, Dr. Jacob has devoted much valuable time and energy to matters affecting the interests of the medical profession. His recent candidature for the office of direct representative has, moreover, entailed a considerable expenditure on his part. It has been arranged that a preliminary meeting of Dr. Jacob's friends shall be held to-day (Saturday), at the Royal College of Surgeons, Dublin, when the arrangements best calculated to promote the success of the proposal will be discussed.

CONTAGION OF TETANUS?

AT the Société de Chirurgie an interesting paper, followed by discussion, was read by M. Larger, which seemed to show clearly that there were good grounds for believing in the contagiousness of tetanus. Four patients who had been treated in the Colmar Hospital were seized with tetanus at different intervals, and all died. The nature and severity of the wounds varied in each case from an amputation to a simple incised wound. The only thing common to them all was that the cases had all occupied contiguous beds. Tetanus is rare at Colmar. None of the patients had had anything to do with horses. A veterinary surgeon, M. Cagnat, had practised castration on horses for twenty-five years without a single case of tetanus. At the end of 1884 he removed with an écraseur a tumour of the testicle in a horse; the animal died of tetanus. Operations for castration practised with the same écraseur on five horses afterwards were followed by tetanus and death in all the animals. The écraseur was then submitted to disinfection by being heated to a high temperature. The instrument was afterwards used for fresh castrations, and without tetanus resulting in any of the animals operated on.

PANTOMIME CHILDREN.

CERTAIN abuses connected with the employment of young children in pantomimes have lately attracted public attention. At a meeting of the London School Board held last week the subject was examined at considerable length by various speakers, in its moral, intellectual, and physical aspects. We cannot now discuss exhaustively each of these considerations. If, however, we may rely upon the evidence of quoted cases which seem to have satisfied the Board, there is reason to believe that the allegations which have been brought against the present system of theatrical management in this particular are not unfounded. Instances are given in which children under ten years of age were employed in pantomime performances, in which the work of rehearsal has interfered with school attendance; and illness, as we may well believe, has been traceable to the late nightly exhibitions carried [illegible] by such young children [illegible] kind of weather, indifferently clad, to homes at the best not very comfortable. Without assuming any censorship of the pantomime as a social custom, we may remind our readers that such abuses, when they exist under the veil of public service, must not be excused by their intention or suffered to continue when they can be removed. This being the case, it clearly behoves managers of theatres and other interested persons either to amend the evils complained of or to disprove their existence.

OPPOSING AUTHORITIES.

ON Monday a conference of Metropolitan Poor-law guardians was held at the offices of the City of London Union to discuss the proposal of the Asylums Board to expend £84,000 in the erection of a permanent hospital at Darenth. A resolution was passed expressing surprise that the managers had again proposed to erect permanent buildings, and a further resolution that the Local Government Board be again asked to receive a deputation on the subject. These proceedings are interesting for the reason that the guardians of the metropolis have, on the one hand, elected representatives who have determined to spend money in a particular way, and, on the other, have appointed certain delegates to prevent such expenditure. If it were intended that the members of the Metropolitan Asylums Board should represent the views of boards of guardians, it is perfectly clear that their election should take place annually. Whether any satisfactory work would be carried on under these circumstances may be a matter for question. But if this intention did not exist, the actions of the boards of guardians in appointing delegates for the purposes of opposition is to be deprecated. It has become too much the custom for different authorities to attempt to interfere with each other's work, and this constant friction between the various boards is distinctly prejudicial to the public interest. There is, we fear, no probability of any diminution in this custom until the constitution of the several authorities is altered, and they are brought into more intimate relation with each other.

NEW METHOD OF EMPLOYING ELECTRICITY IN NEURALGIA.

DR. ADAMKIEWICZ describes in the Polish journal *Przelad lekarski* an exceedingly effective way of applying electricity for the relief of neuralgia of various kinds. The apparatus he uses is a constant current battery, the cathode being a concave metal plate lined with electrical carbon, which is saturated with chloroform. This is then applied over the painful spot, and a current, weak at first but gradually increasing in strength, passed. One or two applications of this kind were found, says the author, sufficient entirely to relieve the severest cases.

PRESCRIBING CHEMISTS.

MR. MORTON-YORK, the city coroner of Gloucester, lately held an inquest on a poor woman who had been recently confined. Her only obstetric attention was from a kindly neighbour, Mrs. Etheridge. The child was born before she arrived. The mother did very well for a day or two; then she seems to have suffered from emphysema and weak heart, ascertained post mortem by Dr. Peacock. She refused to have a medical man, as her husband wished, and the only medicine she had was a draught prescribed by a chemist. The chemist acted quite straightforwardly, but the coroner very properly explained the state of the law under the Apothecaries Act. Under this Act, he said, it was the province of medical men, and medical men only, to prescribe. We commend this case and the view of the coroner to chemists. Surely, the case of a lying-in woman is too

serious a matter to be dealt with by a prescription from a chemist. It is to be regretted, too, that the husband did not disregard the wife's feeling and bring a medical man. Dr. Peacock thought the death due to failure of the heart's action, arising from diseased lung and enfeebled heart and recent delivery, and that even under medical care the result could scarcely have been different. But clearly such a case would have stood a better chance had a medical man been in attendance to direct the administration of suitable food and medicine.

PRACTICE IN RUSSIA BY GERMANS.

SOME discussion has been going on in the German and Russian journals about the possibility of German doctors practising in Russian Poland, it having been affirmed in a Berlin medical journal that a mere formal examination at Dorpat only was required, together with a knowledge of the Russian alphabet and the ability to sign one's name in Russian characters! This, however, is declared by the *St. Petersburger Medicinische Wochenschrift* to be quite a mistake, the Dorpat examinations being very thorough, and it being necessary to remain there under the professor's eyes for a considerable period. It is intimated, too, that the theoretical examinations are even more stringent in Russia than the German Staatsexamen. The University of Dorpat is the only one in Russia where the German language is used. It is, besides, the only one where the M.D. degree can be taken at the time of qualification, all others requiring a year at least to elapse between the qualifying State examination and the higher examination for this degree.

THE EAST MIDDLESEX CORONERSHIP.

THE declaration of the result of the polling which took place in East Middlesex on the 13th inst. for a coroner in the place of Sir John Humphreys, deceased, was made on the 15th inst. The numbers were announced as follows: Mr. Wynne E. Baxter, 1458; Dr. Macdonald, M.P., 1106; Mr. T. Beard, 254; Mr. G. H. Young, 727; and Dr. Porter, 55. The successful candidate proposed a vote of thanks to the returning officer, which was seconded by Mr. Beard and supported by Dr. Macdonald, who stated that he had that day made arrangements for bringing in a Bill making election of a coroner similar to that for a member of Parliament, in consequence of the disgraceful scenes he had witnessed on the polling day.

BOOKS FOR HOSPITALS.

THE Rev. Henry Constable has issued an appeal for periodicals or other literature of a light and wholesome character on behalf of the patients in Victoria Park Chest Hospital. His request will, we hope, be answered by a wide and generous contribution. Everyone can understand the value of such gifts to the sick poor. Debarred by illness from active exercise, and confined in-doors by our uncertain weather, they are still in a great many cases capable of enjoying such quieter intellectual diversions as they safely may. The conversation of fellow-sufferers, each eloquent perhaps on his own complaint, or the consolatory visits of friends, are not sufficient for minds which need all the encouragement they can find to make them happy. In-door amusements are not very numerous, and most of them tend to lose interest by repetition. Of books it may be said that they are unusually free from this disqualification. Their great variety of subject and frequent excellence of illustration render them the almost indispensable companions of the sick at any age. Much depends, however, on the choice of books. There is little reason to fear that works of a serious character will not find their way to a hospital. We would not advocate their exclusion, or even that of studious volumes of a purely secular kind; but the books which will undoubtedly be most useful and by far most eagerly sought after are those which, though sound in tone, are not deep in any way, but light and cheerful in theme and treatment. We need hardly add that other hospitals besides that at Victoria Park are equally in need of these Christmas contributions, and that what is sent should be prepaid.

ITALY AND HYGIENE.

ITALY seems resolved to be no longer behind Europe in sanitary investigation and practice. In view of the International Hygienic Congress to be held at Vienna in the September of 1887, she is already bestirring herself so as to take a prominent and effective part in its proceedings. Through the President of her Royal Society of Hygiene, she is urgently appealing to all Italians engaged, directly or indirectly, on that subject to assemble in force at the Congress, and by their contributions to its discussions, written or oral, to demonstrate the advance she has made in hygienic and demographic science. The President published last year a volume entitled "Les Institutions Sanitaires en Italie," and for 1887 he will issue a sequel to it, showing what Italy has done in practical hygiene from 1882 to that year. Appended to this volume will be a *catalogue raisonné* of all Italian literature on the science which has seen the light between 1881 and 1887; and, to make it as complete as possible, the President invites every compatriot author of a sanitary treatise, memoir, or article to send him a full note of the same. The bibliography of Italy on pellagra, malaria, and cholera is extensive enough, and ought to contain much that is of interest to the hygienists of all countries.

THE CONJOINT SCHEME.

THE Apothecaries' Society have asked from their licentiates an expression of approval of the steps which they propose to take to enable the Society to combine with some other corporation, or to become an independent examining body. No doubt this approval will be readily accorded, and it may be regarded as an indication of a conscientious desire of the Society to obtain the fullest information of the licentiates' wishes, and to give them some share in shaping the policy of the Court of Assistants.

SACCHARINE.

SACCHARINE, which has recently been introduced into therapeutics as an excessively sweet material, three hundred times sweeter than glucose, is likely to prove of considerable service. According to Aducco and Mosso it has very high antifermentative and antiseptic properties. It is recommended for internal administration to diabetics, with a view to rendering their food more palatable. It passes unchanged through the organism, and may be detected in the urine in its original condition. In cases of indigestion or where the intestines are the seat of abnormal fermentations and acidity, it is extolled as an antiseptic.

EFFECTS OF PETROLEUM ON HEALTH.

DR. BIELCZYK publishes in a Polish medical journal the result of his experiences among the workers in petroleum wells. Very violent mental symptoms are produced by acute poisoning by the gaseous exhalations existing in the shafts of the wells, amounting to delirium of a maniacal character. These, however, always quickly cease when the patient is brought up to the earth's surface. Speaking generally, the mortality amongst the workmen is not par[illegible] remarkably free from

diseases of the respiratory organs, both of an inflammatory and a tubercular character, and also from infectious diseases. They are, however, subject to an eruption, like acne, affecting the extremities. Dr. Bielczyk mentions that he has found raw petroleum an excellent application for fresh as well as for old and foul or torpid wounds.

THE MEETING OF THE MEDICAL COUNCIL.

THE General Medical Council is expected to meet on Tuesday, the 15th of February next, at 2 P.M.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Dr. Carl Friedländer, Privat Docent in Pathological Histology, has been granted the title of Professor.

Erlangen.—The number of medical students is now 260, against 233 last winter. A course of dental surgery is now being given to medical students for the first time.

Königsberg.—The nominees for the Professorship of Surgery vacated by Professor Schönborn, who has gone to Würzburg, are Professor Madelung of Rostock, and Professor Mikulicz of Cracow.

Würzburg.—Dr. Kirchener has been appointed to the charge of the Otological clinic.

Tubingen.—Dr. v. Rapp, a former professor, who became a homœopath and was latterly private physician to the Queen of Würtemburg, has just died at Stuttgart.

WE regret to record the death, on the 8th inst., at Ryton-on-Tyne, of Dr. Walter Fergus, until recently resident medical officer at Marlborough College, a post which he had occupied for thirty-seven years. It will be remembered that on his retirement the Council of Marlborough College marked their high sense of Dr. Fergus's services by the grant of a handsome life pension and the placing of his portrait in the College hall, while old Marlburians added a purse of £500, and present Marlburians a silver tea-service. From his long and arduous work at Marlborough Dr. Fergus had recently suffered in health, and his last illness was sudden and brief. The funeral took place at Marlborough on the 14th inst.

THE directors of the Istituto Antirabico (the Anti-rabies Institute) of Milan announce that their bacteriological studies have enabled them actually to diagnose in the dog-bitten the presence of the poison of rabies, and to apply the Pasteur method of cure, with results superior to those hitherto attained by Pasteur himself. They are about to publish a statistical report of the first 500 cases that have come under treatment.

FROM Turin the death is announced of the eminent surgeon, Fedele Margary, known far beyond the circuit of that city for his brilliant operations in its Ospedale di San Giovanni. At his funeral an *éloge* of him was pronounced by the senator, Dr. Bruno, who dwelt on his skill as an operator and his success as a teacher.

THE *Rangoon Gazette* states that General Sir Frederick Roberts, the Commander-in-Chief in India, inspected the European and Native Base Hospitals at Rangoon *en route* to Upper Burmah, and expressed himself well satisfied with the arrangements made there for the care and treatment of the sick and wounded.

A SERIOUS epidemic of diphtheria is reported to have broken out at Ash, near Sandwich, Kent. The village schools have been closed, and every effort is being made by the district authorities to stamp

ON the 13th inst. the death of Dr. Ebenezer Watson occurred at his residence in Glasgow, the result of what he himself regarded as malarial poisoning, contracted at a country house in the early months of 1885. Dr. Watson took a great interest in medical legislation, and his death will be a great loss to the various medical institutions and societies with which he was connected. We purpose publishing a more detailed account of his career in our next issue.

MR. J. W. SCARTH, a Leeds surgeon, was on the 14th inst. fined seven guineas and costs by the stipendiary magistrate for having given a certificate of the death of a child which, it was alleged, he had never visited, but for which he had prescribed, on his son, who had attended the patient, telling him the nature of the illness.

IT is announced that an unexpectedly favourable change has taken place in the condition of Professor von Arlt, the veteran Vienna ophthalmologist, and that an eminent firm of instrument makers have received an order for an artificial leg to replace the limb which was amputated for gangrene.

THE Vienna professorial body, having been asked by the Minister of Education whether it would not be well to place a limit on the number of students of medicine received, has unanimously pronounced against the adoption of any rule of this kind.

THE Wolverhampton Board of Guardians, in appointing a new medical officer, have decided to make all extra fees inclusive of salary. This practice is stated to be followed by the whole of the other unions in Staffordshire.

DEGREES FOR LONDON MEDICAL STUDENTS: REPORT OF THE DELEGATES.

THE following report, dated Dec. 6th, 1886, of the Committee of Delegates, appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England, to consider the question of the desirability and practicability of granting degrees in medicine and surgery to persons who have passed the conjoint examinations of the two Colleges, was presented at the special meetings summoned for the 16th inst.

On July 7th, 1885, a preliminary report to the two Colleges was adopted by the Committee of Delegates, expressive of their opinion that it was both desirable and practicable that persons examined by the two Colleges, acting conjointly, should, in virtue of that examination, have a degree in medicine and surgery conferred upon them. That preliminary report was referred by the Royal College of Physicians to their Council, and by the Council of the Royal College of Surgeons to a Committee, to consider the same and to report thereon to the respective Colleges; and the Council of the College of Physicians and the Committee of the College of Surgeons having duly reported thereon, the two reports were referred to the Committee of Delegates.

The two reports having been duly considered, the Committee of Delegates have now to recommend to the two Colleges the approval and adoption of the following resolutions—viz.:

1. That candidates who have passed the examinations of the examining board in England for the licence of the Royal College of Physicians of London and the diploma of member of the Royal College of Surgeons of England should have a degree in medicine and surgery conferred upon them, provided that they have passed such examination in arts and science as may hereafter be defined; and have pursued clinical studies in London—or in other medical school or schools if the governing body should so determine—for at least two years after having passed the second professional examination.

2. That an application be made to the Crown by the

Royal College of Physicians of London and the Royal College of Surgeons of England, acting conjointly, for power to confer degrees in medicine and surgery.

The Committee of Delegates have further to recommend to the two Colleges the approval and adoption of the following statement, setting forth the reasons for granting to the Colleges, acting conjointly, the power of conferring degrees in medicine and surgery—viz.:

I. It is a reasonable demand that London students should be able to obtain medical degrees in London, provided that their course of study, their opportunities for practical instruction, and the examinations to which they are subjected are commensurate with those which prevail in the majority of the universities of the United Kingdom.

II. The natural way of meeting this demand would seem to be that the Royal College of Physicians of London and the Royal College of Surgeons of England, acting conjointly, should acquire the power of conferring medical degrees, so that they and the schools associated with them should become *de jure*, as they already are *de facto*, a medical university.

III. The essentials of a university as regards teaching and the means of study in medicine exist in London more fully than anywhere else in England—viz.: (*a*) The teachers in London include men of the highest eminence in the several branches of medicine. (*b*) London possesses unrivalled clinical advantages for medical education in its large and well-appointed general hospitals, containing upwards of 5000 beds, occupied by about 60,000 patients a year, with out-patient departments attended by not less than 350,000 persons; its special hospitals, with more than 3000 beds; and its lunatic asylums with upwards of 5000 beds. (*c*) What has been stated of the advantages for clinical teaching applies in an equal degree to the study of morbid anatomy and pathology. (*d*) As regards the teaching of the preliminary subjects of medical study, advantages equal to those of universities exist in the London medical schools. (*e*) The organisation of the London medical schools, and the intercourse of the students with one another and with their teachers, constitute a further condition of university life, which has a marked and important educational influence.

IV. The examinations of the Colleges in the subjects of study comprised in their curriculum are on a level with those of the majority of the universities of the United Kingdom.

V. Whilst the essential conditions of university education in medicine exist in London, it would lead to their fuller and more complete development, and to the encouragement of higher education, if degrees—which are the recognised proof of the completion of a university course—were conferred upon the students who have virtually passed through such a course.

VI. It is contrary to the interest of the public that students should be induced to go from London to places where the opportunities for clinical studies are necessarily far inferior, merely because university degrees can there be obtained.

VII. There seems to be no just ground for objecting to the creation of a new university, seeing that a university has just been founded—which confers a power, such as that now claimed for London, on Manchester and Liverpool. Other possible objections may be made and answered as follows—viz.:

It may be objected—(*a*) That there would be two universities in one city. The case of Dublin may be cited which has its two universities. (*b*) Or that the new university would consist of one faculty only. Precedents may be found—notably in the case of Montpellier—in which a university originally consisted of a medical faculty only; and in the universities of the United Kingdom, in which, at their foundation, rarely more than two faculties were included. (*c*) Or that other medical corporations would seek similar powers. In other cities in which medical corporations exist, local universities are already established, affording means of graduation such as are not available for the great majority of students in London. (*d*) Or that it would be difficult to find an appropriate title for the new university. The new university would naturally receive a distinctive designation—for example, University of Westminster.

VIII. It may be said that the students educated in London can obtain degrees from the University of London, but, for reasons into which it is not here necessary to enter, the University of London does not supply the present want, as is obvious from the following fact: of 16,192 medical men practising in England, 5219 possess M.D. or M.B. degrees; but of these, only 622 derive their titles from the University of London.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following is a copy of the circular sent to every Fellow of the College:—

SIR,—You are doubtless aware that by the Charter of the College, dated the 14th of September, 1843, "a new class of Members" was created "to be called Fellows," and in that Charter it was provided that none but Fellows should thenceforth become members of the Council, and that the right of election of members of the Council should vest in the Fellows alone.

The Council having decided to seek alterations in the Charters to enable Fellows to vote by voting-papers, without personal attendance, at the election of the Council, and to effect other changes therein, an application has been addressed to the Council by some Members of the College requesting the Council to seek further alterations in the Charters so as to enable Members to take part in the election of the Council and to be themselves eligible for seats on the Council.

The Council will be glad if you will answer the questions printed on the fly-leaf of this circular, appending thereto your signature and address, which will be treated as confidential, and return the same to me, not later than Friday, the 31st inst., in the enclosed stamped envelope.

I am, Sir, your obedient servant,
EDWARD TRIMMER, Secretary.

Lincoln's-inn-fields, W.C., Dec. 9th, 1886.

Circular to Fellows.

	Answer.
(*a*) In your opinion should Members of the College be allowed to vote for Fellows as members of the Council?	
(*b*) In your opinion should Members of the College be eligible for seats on the Council?	

Signature of Fellow _____

Address _____

To Edward Trimmer, Esq., Secretary, Royal College of Surgeons of England, Lincoln's-inn-fields, W.C.

ADDRESS BY PROFESSOR BOTKIN ON THE CIRCUMSTANCES ATTENDING THE SUICIDE OF THE LATE PROFESSOR KOLOMNIN.

THE following is an outline of an address delivered by Professor Botkin at a meeting of the St. Petersburg Society of Russian Medical Practitioners, held in honour of the memory of the late Professor Pirogoff, at which the deceased Professor Kolomnin himself was to have delivered the address.

On the 11th (23rd) of November, at 12 o'clock, Professor Sergei Petrovich Kolomnin terminated an irreproachable career by a shot in the right temple. The deceased left the following letter addressed to the Senate of the (Military Medical) Academy:—"Last week people's minds seemed to have become clouded over on account of the disastrous result of an operation. I am not to blame. I wished to do what was right. I desire that Dr. Morozoff and others may not be considered to blame.—S. KOLOMNIN." On the 6th (18th) of November the operation which ended so unfortunately was performed. Five days later S. P. Kolomnin was no more. All who knew Sergei Petrovich as a man humane in the highest degree, holding, too, a foremost place in the ranks of science, found it impossible to believe that he could have committed an error so grave as to call for such severe self-condemnation. Scientific men and the public were shocked by the occurrence, and different views were expressed concerning it. While some looked upon it as a heroic action others stigmatised it as cowardice. Having known Sergei Petrovich for more than ten years as a colleague in the Academy and as the best adviser on surgical matters, being also well acquainted with his character, it is gratifying to me to be able to throw some light on [illegible] to me in the clinic on

Nov. 10th (22nd) and asked me to supply his place at the present "Pirogoff meeting" of the Society, at which he had to deliver an address, but did not feel sufficiently well after his misfortune to fulfil his engagement. On Oct. 27th (Nov. 8th) a female patient, aged twenty-three, was seen in my out-patient department by Dr. Pokrovski, ordinator (chief assistant) in my clinic. He diagnosed an affection of the rectum, and sent her into the surgical clinic, where Sergei Petrovich (Kolomnin) examined her, finding an ulcer as large as half the palm of the hand, of a tuberculous character, as he believed, this view being upheld by the presence of some tumours. He decided to scrape and subsequently to cauterise the lesion. In order to produce anæsthesia he had fifty grammes of a 5 per cent. solution of hydrochlorate of cocaine prepared; of this thirty grammes were brought into use, containing exactly twenty-four Russian grains of the salt, or twenty-three English grains [the Russian grain is exactly one-sixteenth of a gramme], six grains being injected at a time into the rectum. After the third of these injections it was found on examination that the part was still sensitive. A speculum was then introduced, the ulcer dabbed with a dry sponge, and then the fourth injection given, making twenty-four grains in all. After this the parts were tolerably anæsthetic. The ulcer was scraped, and a tampon saturated with oil inserted. The pulse was then accelerated. During the operation the patient groaned, so that even the twenty-four grains had not produced complete anæsthesia. After the operation Sergei Petrovich (Kolomnin) went round his ward, and in three-quarters of an hour a message was sent to him that the patient was very low. He found the pulse very weak, the face and hands cyanotic, and the respiration laboured. He considered that she was in a toxic state, and used every means to bring her round, Prof. Sushchinski being also invited to a consultation. Faradisation, artificial respiration, hypodermic injection of ether, administration of ammonia, tracheotomy for the inhalation of oxygen, stimulating and nutrient enemata—all were tried, but without success. Sergei Petrovich (Kolomnin) had no doubt that death was due to cocaine. To what extent was he to be blamed for introducing so large a dose as twenty-four grains into the body? Some time before the operation he asked Professor Sushchinski about the dose of cocaine, and he told him that he considered two grains as the maximum. He however collected a number of special papers on the subject in which some thirty cases of cocaine anæsthesia were reported where from six to eighty, and even ninety grains had been administered. Most of them were cases of lithotripsy. Of course he knew that the bladder, when healthy, cannot absorb such a quantity of cocaine, but some cases of diseased bladder were mentioned where there must have been absorption. Finally, Dieulafoy had performed an operation similar to Kolomnin's, introducing into the rectum forty-eight grains all at once with complete success, and this served as a guide. He, however, observed additional precautions, employing only half the quantity and introducing it in divided doses. How far was he to blame? He certainly put too much faith in Dieulafoy's case, but anyone else might have done the same.....It is difficult to account for the French surgeon's success. It is indeed possible that, as his operation was performed at a time when cocaine was dearer than gold itself, being two shillings a grain, it may have been adulterated, and therefore the proper effect was not produced. At all events, whatever blame is due to Sergei Petrovich is greatly lessened by the records in medical literature. He himself, besides, said that he was not to blame regarding the operation, but only with reference to his therapeutics. "I blame myself," he said, "most of all for making an incorrect diagnosis; the diagnosis of tubercle was not confirmed. I ought not to have operated at all, and the patient would have been still living. In spite of my not being to blame, I cannot help feeling at times that I killed her."

Gentlemen, you know that diagnosis during life is always only a hypothesis of a more or less correct nature. There may always be a mistake, and only a serious blunder is inexcusable. In the present case the ulcer was scraped and cleaned, and it was impossible to show during life that it was not tuberculous. But even if the diagnosis had been incorrect, why did he blame himself so seriously and then punish himself in such a way? As the circumstances do not supply a sufficient answer to this question, we must look for it in the condition of Sergei Petrovich himself. He w[illegible] flining himself entirely to his scientific work, so that he made no intimate friends. Whether it was from his personal condition or from surrounding circumstances, his character grew year by year more reserved, and for the last few years he lived quite in seclusion. He was very strict, both with other people and with himself. He was highly sensitive, and no doubt had a pathological nervous system. He had consulted me for palpitation and sleeplessness. When I saw him after the vacation he was restless and irritable. He was constantly alone and showed great tendency to impatience, and after the unfortunate occurrence his equilibrium seemed to be quite upset. On the Sunday he attended the post-mortem examination, expecting to find some disease of the internal organs. None, however, was discovered, and he satisfied himself that the cocaine must have been the cause of death. On the Monday he came to me in a very depressed condition, with a pile of reports of cases of cocaine anæsthesia. I begged him not to lay this case so much to heart, and after a time he became more composed, and promised to come to this meeting and explain the whole of the circumstances to the Society, but he added, "I can't promise for certain." He was repeatedly moved to tears when talking over the case..... Taking into consideration all these things, we must conclude that when he committed suicide he was not fully responsible for his actions. Indeed, I think that I myself, and all of us, are really to blame for his death, because in the time of his dire distress we did not sufficiently hold out the hand of sympathy to him.

The meeting broke up in solemn silence.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5553 births and 3984 deaths were registered during the week ending Dec. 11th. The annual death-rate in these towns, which had been 19·1, 20·1, and 21·0 per 1000 in the preceding three weeks, further rose last week to 22·9. During the first ten weeks of the current quarter the death-rate in these towns averaged 19·7 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 12·1 in Brighton, 17·0 in Birkenhead, 17·7 in Hull, and 18·0 in Birmingham. The rates in the other towns ranged upwards to 29·2 in Manchester, 30·1 in Derby, 30·5 in Blackburn, and 33·3 in Wolverhampton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 399 and 379 in the preceding two weeks, rose again last week to 424; they included 181 from measles, 65 from scarlet fever, 60 from whooping-cough, 50 from "fever" (principally enteric), 35 from diarrhœa, 32 from diphtheria, and 1 from small-pox. The lowest death-rates from these zymotic diseases last week were registered in Bolton and Birkenhead, and the highest rates in Halifax, Leeds, and Wolverhampton. The greatest mortality from measles occurred in Huddersfield, Leeds, Halifax, and Wolverhampton; from whooping-cough in Bristol and Huddersfield; from scarlet fever, in Leicester, Salford, and Bristol; and from "fever," in Preston and Salford. The 32 deaths from diphtheria in the twenty-eight towns included 14 in London, 7 in Liverpool, 3 in Portsmouth, and 2 in Huddersfield. Small-pox caused no death in London and its outer ring, 1 in Leeds, and not one in any of the twenty-six other large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding five weeks from 293 to 444, further rose last week to 494, and exceeded the corrected weekly average by 25. The causes of 97, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Newcastle-upon-Tyne, Nottingham, Cardiff, Birkenhead, and Plymouth. The largest proportions of uncertified deaths were registered in Halifax, Oldham, Sheffield, and Salford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·4 and 23·1 per 1000 in the preceding two

weeks, declined again to 22·0 in the week ending Dec. 11th; this rate was 0·9 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·8 and 17·0 in Leith and Edinburgh, to 22·8 in Dundee and 26·8 in Glasgow. The 544 deaths in the eight towns last week showed a decline of 26 from the number in the previous week, and included 17 which were referred to scarlet fever, 15 to whooping-cough, 15 to diarrhœa, 6 to diphtheria, 5 to measles, 5 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 63 deaths resulted from these principal zymotic diseases, against 64 and 81 in the preceding two weeks. These 63 deaths were equal to an annual rate of 2·6 per 1000, which exceeded by 0·2 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of scarlet fever, which had been 14 and 25 in the previous two weeks, declined again last week to 17, of which 12 occurred in Glasgow and 3 in Edinburgh. The 15 deaths from whooping-cough also showed a decline from the numbers in recent weeks, and included 9 in Glasgow and 4 in Edinburgh. The deaths attributed to diarrhœa, which had declined in the seven preceding weeks from 46 to 17, further fell last week to 15; 7 were returned in Glasgow, 4 in Aberdeen, and 3 in Dundee. The 5 deaths referred to "fever" (of which 2 occurred in Glasgow) showed an increase of 2 upon the low number in the previous week; whereas the fatal cases, both of diphtheria and measles, had declined. Four of the 5 deaths from measles occurred in Glasgow; and 2 deaths from diphtheria were returned both in Glasgow and Dundee. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 125 and 142 in the preceding two weeks, further rose last week to 144, but were 34 below the number in the corresponding week of last year. The causes of 59, or nearly 11 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had increased in the preceding four weeks from 23·6 to 28·1, further rose to 35·6 in the week ending Dec. 11th. During the first ten weeks of the current quarter the death-rate in the city averaged 25·1; the mean rate during the same period did not exceed 18·2 in London and 19·0 in Edinburgh. The 241 deaths in Dublin last week showed a further increase of 51 upon the numbers returned in recent weeks, and included 8 which were referred to scarlet fever, 8 to diarrhœa, 4 to "fever," (typhus, enteric, or simple), 3 to whooping-cough, and not one either to small-pox, measles, or diphtheria. Thus 23 deaths resulted from these principal zymotic diseases, against 22 and 21 in the previous two weeks; they were equal to an annual rate of 3·4 per 1000, the rates from the same diseases last week being but 2·1 in London and 1·6 in Edinburgh. The fatal cases of scarlet fever corresponded with the number in the previous week; those of diarrhœa and whooping-cough showed an increase, while those of "fever" had declined. Five inquest cases and three deaths from violence were registered; and 58, or nearly a quarter, of the deaths occurred in public institutions. The deaths both of infants and of elderly persons showed a further increase upon recent weekly numbers. The causes of 50, or nearly 21 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

BURMAH.

IN THE LANCET last week, in enumerating the medical officers serving in Upper Burmah, we inadvertently omitted mention of the name of Mr. Mackinnon, of the Army Medical Department, who was for some time the principal medical officer in Upper Burmah. Mr. Mackinnon remained at Mandalay in administrative charge until August, when he was replaced by Mr. Farrel, of the Indian Medical Service.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon Philip Broke Smith, M.D., to be Deputy Surgeon-General, vice S. Fuller, retired; Brigade Surgeon William O'Halloran, from half-pay, to be Brigade Surgeon, vice P. B. Smith, M.D. The promotion of Surgeon-Major Henry William Alexander Mackinnon to the rank of Brigade Surgeon is cancelled, this officer having been granted the distinction of Companion of the Distinguished Service Order.

ADMIRALTY.—The following appointment has been made: Walker John E. Sumpter, M.R.C.S., L.S.A., to be Surgeon and Agent at Sherringham, Norfolk.

ARTILLERY VOLUNTEERS.—1st Fifeshire: Surgeon David Archibald resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the corps on his retirement.

RIFLE VOLUNTEERS.—3rd Volunteer Battalion, the Lancashire Fusiliers: Surgeon G. G. Tatham, M.D., resigns his commission.—2nd Volunteer Battalion, the Norfolk Regiment: David Chadwick Smith, Gent., to be Acting Surgeon.—5th Surrey: Surgeon G. F. White resigns his commission.

THE VOLUNTEER MEDICAL STAFF CORPS.—The Edinburgh Division: German Sims Woodhead, Gent., M.B., to be Surgeon.

Correspondence.

"Audi alteram partem."

THE FELLOW, THE MEMBER, AND THE FRANCHISE.

To the Editor of THE LANCET.

SIR,—I must be excused from attempting to follow your correspondent "Historicus" in an inquiry into my "motives" for taking the course I have felt it my duty to pursue in reference to the questions now at issue at the College of Surgeons, as well as into an explanation of "the part" which, according to him, I am "now playing." His remarks on these points I leave with confidence to be dealt with by the good taste of your readers—as I do his criticisms by their good sense. Nor have I any "personal justification" to offer or any "apology" to make to any man or to any body of men. In freely and openly stating my views at a public meeting on a public question, and in addressing my brother Fellows through the press on a matter that closely affects my and their collegiate interests, I need no justification, and most certainly will offer no apology.

But to pass from this personal question which your correspondent has raised, he asserts that there is scarcely a statement I make or an inference I draw that may not be controverted. But yet he altogether fails to disprove statements such as these: that the College of Surgeons has, under its present form of government, attained an unparalleled prosperity; that the value of its diploma is rising in professional and in public estimation; that so little importance does the great body of its Members appear to attach to the franchise, that out of more than 4000 who could five years ago have easily acquired it only nine availed themselves of that privilege; that the Council as at present constituted is a thoroughly representative body; and that the Members of the College have never possessed the elective franchise, the self-election of the Council up to the period of the institution of the Fellowship being a Charter right. These are a few of my statements that he has not succeeded in controverting.

Your correspondent misquotes me in respect to the questions of the Fellowship of the Royal Society. What I say is this: "Many of the Fellows possess the coveted distinction of the F.R.S.; how many, if any, of the Members *who have not sunk the Membership in some higher university degree* I know not." He omits the sentence I now put in italics. But this comprises the whole gist of the matter Many of the leading physicians in London who now possess the F.R.S. took the Membership of the College on the completion of their studies, in order to have a qualification whilst working and waiting for the M.D. degree. But they have so effectually sunk the M.R.C.S. under the degree that they never append it to their names in their publications or in the rolls of the Societies, and the only clue to their connexion with the College of Surgeons is to be found in the list published in the Calendar of that institution.

In conclusion both of this letter and of this correspondence, let me say this, in justice to others, that the publication of my pamphlet at the time that the Council was about to issue its circular to the Fellows was an accident, determined solely by [illegible] the pamphlet is simply

an amplification of what I said on Nov. 4th; and further, that I alone am responsible for every opinion, statement, and inference contained in it; not a single member of Council or official connected with the College had the faintest idea that such a pamphlet would appear. With me rests the sole responsibility of its publication, and of its circulation amongst the Fellows. "*Laudatur ab his, damnatur ab illis*," might well be its motto; for if, unhappily, it has provoked the hostility of "Historicus" and his allies, I am consoled by the commendations it has called forth from those whose opinions I most value.

I am, Sir, yours faithfully,

Dec. 14th, 1886. ——— JOHN ERIC ERICHSEN.

To the Editor of THE LANCET.

SIR,—The thanks of every Member of the College of Surgeons are due to "Historicus" for his brilliant rejoinder to Mr. Erichsen in your last issue. No more opportune moment could have been chosen for this reply than the eve of the poll that the Council of the College is taking of its Fellows, on the subject of what is now popularly called the "Members' Franchise." Mr. Erichsen has, we understand, in a mistaken sense of duty, sent to every Fellow a copy of his speech at the College on the 4th, or rather of what that speech might have been if time had permitted on that occasion; and now that the other side of the question is thus clearly brought home to them, the Fellows will have an opportunity of forming an unbiased judgment; attack and defence are each set forth, and for the present the matter is in the hands of the Fellows. The Association of Members has not thought it to be becoming to go cap in hand to beg for the votes of the Fellows; but what a body of men cannot gracefully ask for itself may, without loss of dignity, be asked for by others. If the result of the poll is adverse to our claims—as it may be from the fact that the College Council has not seen fit to lay the entire resolution adopted at the general meeting before the Fellows,—we have still the Privy Council to approach, and, if that body should not grant our petition, we have, beyond that, the Houses of Parliament. We trust, however, that in the College itself this reform may be carried out, and that when the Privy Council is approached it may be by a united body, the President and Council praying that the new Charter may contain the provisions we desire. For our own part, we have always endeavoured to keep the issue simple, and, leaving aside all questions of change in other corporations and colleges, shall continue to ask for reform in our own College of Surgeons, and that alone. When that is accomplished, it may be that other corporations will be only too anxious to follow a good example, and their councils, anticipating the desires of their diplomates, themselves throw open the portals. But one door is sufficient for us to knock at.

We are, Sir, your obedient servants,

WARWICK C. STEELE,
WM. ASHTON ELLIS,
Hon. Secs. Association of Members of the Royal College of Surgeons.

THE FELLOWS, MEMBERS, AND COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—As a Fellow of the Royal College of Surgeons, I have been asked to answer two questions: 1. Whether in my opinion, Members should have a vote for the election of the Council? 2. Whether, in my opinion, Members ought to have seats on the Council? I have answered the latter question by a decided "Yes." The Members are a highly educated and able body of surgeons. The average Member of to-day is probably the equal to, or perhaps the superior, of the average Fellow of twenty years ago (about my own standing). From their ranks many able men of ripe experience might be picked whose services on the Council might be invaluable to the College. The other question I have answered in as decided a negative. "Historicus" argues, in your columns, from the history of the College prior to the present century that the Members have a "moral right" to the so-called "franchise." This is beside the question. The real question is, Is it desirable in the interests of the College that the Members should have a voice in electing the Council of the great College which has charge of the interests of the profession of surgery?" I do not think that, although from what I have already said as to the propriety of Members having seats on the Council it will be understand that I cordially admit their fitness to exercise the franchise, the proposed concession would give them real *representation*, or that it would tend to improve the quality of the Council. In such a constituency as is proposed, an election would be followed by one of two results: either the seats on the Council would be placed at the disposal of the larger medical schools, or they would be at the mercy of some powerful association. As a matter of fact, a recent experiment in what is practically an almost identical constituency has proved that the latter of the two alternatives would operate. Reference to page 1172 in the current number of the *Journal* of the British Medical Association will show that such a result was actually calculated upon by the moving spirits of the Association. I find no fault with the list of able men who have been, through the influence of the Association, selected to represent the profession in the Medical Council. I am prepared to go further, and say that no other body than the British Medical Association, *as at present constituted*, could be better entrusted with the appointment of representatives of the profession. I submit, however, that the appointments of so-called representatives through the influence of a powerful Association is not *representation* at all. I am a member of the Association; I cordially acknowledge the useful work it has done and is doing, and I believe that it still has much useful work before it; but the life history of all Associations should teach us that the day will come when it will not be safe to entrust the control of the affairs of a great institution like the College of Surgeons to its waning vitality. In framing its new Charter, the College will have to legislate not only for to-day but for the future. The remedy for the alleged abuses in the present constitution of the College will not be found in direct (so-called) representation. I must confess to a feeling that to a certain extent the grievances of the Members are more sentimental than real. Those who are out of office look on things with very different eyes to those that are in. I can remember the time when some of those now on the Council were clamouring for reforms of which riper experience and a closer insight into the affairs of the College have convinced them of the inexpediency. Thus the reformers of yesterday become the Conservatives of to-day. Still there may be room for reform. Certainly the Council is not infallible; witness its present mistaken attitude towards the Apothecaries' Company. Something ought to be done to make things pleasanter between the Council and the Members. The admission of Members to seats on the Council would do something. To supplement this, I think that a scheme of *indirect* representation might be devised, which, while respecting the "moral rights" of the Members, would secure the election of a fairly representative Council. I would suggest that under the new Charter Members should take part in the formation of the elective constituency. Thus: let the Honours Examination for the Fellowship continue, as at present, to entitle to the franchise, but let the Members have the privilege of electing, *honoris causâ*, a certain number of Members of not less than ten years' standing to the Fellowship. With such a provision, and the concession to the Members of the privilege of sitting on the Council, a sound representation would, I think, be secured.

I remain, Sir, yours faithfully,

Rowlands, St. Mary Cray, Dec. 13th, 1886. C. H. ALLFREY.

To the Editor of THE LANCET.

SIR,—The circular addressed to the Fellows of the Royal College of Surgeons does not fairly place before them the issue upon which their opinion is asked. In answering it, however, it may be put right by adding the words "if of ten years' standing" to the first question, and "if of twenty years' standing" to the second. Whilst I have no doubt as to the propriety of admitting the Members to the franchise, I do not think it at all necessary to give them the privilege of a seat on the Council. There are a great many Fellows scattered all over the country, occupying a high scientific as well as social position, who are general practitioners, and quite competent to safeguard the interests of the profession

in all respects, if elected to the Council; and in my opinion it would not be wise so greatly to enlarge the area of selection as would be the case were the second proposition carried into effect.—I am, Sir, yours obediently,

Norwich, Dec. 15th, 1886. THOS. W. CROSSE, F.R.C.S.

To the Editor of THE LANCET.

SIR,—The circular from the College of Surgeons to ascertain the opinion of the Fellows upon the vital principle of representation of Members upon the Council has been issued, and I venture to say is found by most of an unsatisfactory character. These are the questions asked:—(*a*) In your opinion should Members of the College be allowed to vote for Fellows as members of the Council? (*b*) In your opinion should Members of the College be eligible for seats on the Council? In answering them I hope each Fellow will ignore the unqualified nature of the questions, and state his views more broadly, and rather with reference to the resolution submitted and carried at the last general meeting of the Fellows and Members on Nov. 4th—viz., "That it would conduce to the welfare of the College, and tend to promote the interests of medical polity and education—(*a*) if Members of ten or more years' standing were empowered to vote (separately or conjointly with Fellows) in the election of the Council; and (*b*) if Members of twenty or more years' standing were eligible to sit in the Council to the extent of not more than one-fourth of the Council." I would also ask the Fellows to take this opportunity of expressing their opinion on the action of the Council in lowering and depreciating the status of the Fellowship, by the adoption of a modified examination to Members of a certain standing—a measure inflicting great injustice upon the younger Fellows (especially the provincial ones) in many ways, though perhaps of little moment to those senior ones who hold seats on the Council. The Fellowship was an evidence of a thorough anatomical and surgical knowledge, and to obtain it extra years of study were required, often involving no little sacrifice. The profession and the public relied upon it. It will be so no longer. By their action in this, and by their conjoint action with the College of Physicians in refusing to co-operate with the Apothecaries' Society to bring about practically a one-portal system for London (so much to be desired by all who have the welfare of the profession at heart)—by these two acts alone the Council have shown their inability "to read the signs of the times," and have forfeited the confidence of not a few of their present constituents. The time has come when a radical change in the management of the College is not only desirable, but absolutely necessary. I could have said much more on both the above topics, but fear to trespass on your valuable space. The legal right of Members has been so fully discussed that further comment is unnecessary. In conclusion, I will mention briefly a few of the alterations that might fairly be conceded, and which would probably benefit the College, its Fellows, and Members. (*a*) The Council to consist of three-fourths Fellows elected by Fellows only, and one-fourth either Fellows or Members elected by Members only. Voting-papers to be permitted. (*b*) The president of the College to be a Fellow or Member of a certain standing, and elected annually at a general meeting of Fellows and Members. (*c*) The recent modifications affecting the status of the Fellowship to be abolished. The Council to have the privilege of recommending not more than two members of the profession distinguished in surgery for election to the Fellowship at each annual meeting. (*d*) No alteration to be made in the Charter without consulting the Fellows and Members at a general meeting to be called for that purpose.

I am, Sir, your obedient servant,

December 16th, 1886. F.R.C.S.

To the Editor of THE LANCET.

SIR,—Your leading article in this week's issue must echo the sentiments of many provincial Fellows. For some years the academic status of the diploma has degenerated. Not only has the preliminary educational standard been lowered, but even the Primary has been rendered easier by giving a selection of questions to be answered instead of the compulsory "all four" as formerly obtained. Now the Council, without consulting the general mass of Fellows, propose to still further depreciate the title by admitting, without any test of their fitness for such an academic distinction, a certain number of Members annually, and, secondly, to admit any Members of fifteen years' standing to the Pass without subjecting them to what you have justly called the *pons asinorum* of aspirants—the dreaded Primary. What privileges have the general mass of provincial Fellows? They care little about the rights of voting, and a seat on the Council, as is rightly urged in your leader, is within the reach of a very small minority. Have they ever been consulted on vital questions relating to the College till this last week? The chief privileges, then, of provincial Fellows are the academic distinction and status the title gives them. However wisely and delicately the proposals of the Council are carried out, many an injustice would be done to Fellows in small provincial towns, where the value of the Fellowship has begun to be appreciated. An imaginary case may easily be drawn. An M.R.C.S., through hard work and local influence, has acquired a large practice; he is a good all-round man, but not in any way well read or of any scientific learning. He is acquainted with many London Fellows from having sent them cases up from the country periodically. Without the slightest trouble he would receive the highest honour the College could confer on him, without ever having read for or passed anything but a minimum examination. Not only does he suddenly become the academic equal of the man who has devoted three or four years to the acquisition of the title, but he really becomes his superior, for it cannot but get bruited abroad that the Fellowship was conferred on him because he merited it, whilst the other man only got it by examination, and any man can pass examinations who has (not necessarily brains) but time, money, and applicability. Where then would be Sir Benjamin Brodie's explanation of the origin and institution of Fellows? It seems as if the London Fellows (as represented by the mass of the Council) hope to retain their vested interests by simply diluting them with a batch of new Fellows. The provincial Fellows, on the other hand, wish the integrity of the title to be maintained, or, if possible, made more select still. Let the Members have their electoral rights, and let them even have a chance of a seat on the Council under certain restrictions, and what have the Council to fear? The following two paragraphs, taken from a letter signed "Historicus," in your issue of Dec. 11th, deserve repetition and re-repetition: "The academic status (of the Fellowship) is being persistently debased in the silly hope of allaying the disaffection of a few Members by the offer of a cheap but degraded Fellowship"; and "The truth is, that the intellectual and professional prestige of the Fellowship is being seriously prejudiced by its forced association with an exclusive and obnoxious electoral privilege—a privilege, be it remembered, which is also an usurpation."

I am, Sir, yours faithfully,

Dec. 13th, 1886. A PROVINCIAL FELLOW.

THE HOSPITAL FOR WOMEN, LIVERPOOL.

To the Editor of THE LANCET.

SIR,—I shall feel much obliged by an early insertion of the enclosed in THE LANCET.

I am, Sir, yours faithfully,

Rodney-st., Liverpool, Dec. 12th, 1886. J. CAMERON, M.D.

4, Rodney-st., Liverpool, Dec. 12th, 1886.

DEAR SIR,—In a letter addressed to you by Dr. Imlach, and published in THE LANCET of the 11th inst., my resignation as a member of the "Hospital Inquiry Committee" is referred to in the following ambiguous terms: "On March 8th, Dr. Cameron visited the Hospital for Women as one of the delegates from the Inquiry Committee. In the presence of yourself and the vice-president, the case-books, hospital registers, and various memoranda were examined, and the lady superintendent and nursing staff subjected to a severe cross-examination. At the next meeting of the Medical Institution, he resigned from the Inquiry Committee, declining to serve any longer." To prevent any misunderstanding, I venture to trouble you with an explanation of the cause (omitted by the writer) of my resignation. After my visit with Dr. Alexander to your hospital, Dr. Imlach was taken seriously ill, and for a time his life was in extreme danger, and I was reluctant, under these circumstances, to continue an inquiry which, by the anxiety it was likely to occasion, I feared would aggravate his condition. I

availed myself of the first opportunity (the meeting of the Medical Institution alluded to by Dr. Imlach) to tender my resignation, stating publicly to the members the grounds of that step. I should wish to add that I highly approve of the report of the Inquiry Committee, which, I consider, takes a very moderate view of the objections to the operation in question. I remain, dear Sir, yours faithfully,

J. CAMERON, M.D., &c.

The President, Hospital for Women, Shaw-street.

P.S.—I am sending a copy of this letter to THE LANCET.

ARE SMALL-POX AND COW-POX ONE AND THE SAME DISEASE?

To the Editor of THE LANCET.

SIR,—In reply to Mr. Fleming's query, I would remind him of the following points:—The physical characters of the microbes both of small-pox and vaccinia are identical, if we neglect difference of size. In both diseases the micrococci tend to arrange themselves in groups of four, and in the early stages the Malpighian mucosus is the site selected for the development of each. Pincus's description of the microscopical changes in vaccinia corresponds closely with that by Weigert of the early development of the small-pox pustule. Localisation in vaccinia probably results from the local nature of the inoculating process, the irritated parts offering the most eligible sites for exhaustion of the local manifestations. If these were excised within forty-eight hours of inoculation a more generalised exanthem would show itself (Chauveau). Infection in variola is general, not local. Constitutional symptoms consequently precede the rash. The process is centrifugal. In vaccinia the process is centripetal, and general symptoms, when present, come late. When variola is *inoculated* the same thing happens, but then the infective process is sufficiently vigorous to induce secondary general infection and a disseminated eruption. Mr. Fleming can scarcely question the identity of cow-pox and vaccinia. He, however, dislikes the term "attenuation," though he will scarcely deny that Pasteur and Toussaint have independently proved the possibility of attenuating the virus of charbon by the aid of altered temperature, or that they have *fixed* the attenuation thus obtained, so constituting of it a generic character. If this be possible with other microbes, why not with that of variola? Man's temperature is about 37·5°C: ‡°C higher in the horse, and as much higher still in the cow. These conditions, judging from analogy, are those favourable to attenuation. Virus from horse-pox or from cow-pox induces in man a characteristic eruption; the former sometimes causing marked constitutional symptoms with stray vesicles; the latter is less active, and seldom develops to so great an extent. But, after passing through the cow, horse virus loses its excessive activity, and acquires the name of cow-pox, which, when used for inoculating man, causes no general symptoms. Repeated inoculations of cow-pox on other cows tend to fix the character of the virus—corresponding thus to the fixed attenuations of charbon virus mentioned above. In plants, modifications corresponding to such attenuations are possible. Why not with microbes? Many authors have deemed it right to affirm that variola, horse-pox, and cow-pox are not only interchangeable, but that infection with one of them is necessary to the production of the disease itself in the others. May we not go a step further, and suggest that the *same cause*—a specific virus floating in the atmosphere—may account for all of them, any differences being satisfactorily explained by variations of soil and temperature? In this way so-called "spontaneous cow-pox" would be easily accounted for; the protective power of any one disease as against infection with the others would be more easy to understand, and it would be unnecessary to say, with Mr. Fleming, "that small-pox and cow-pox were different and antagonistic diseases." Though man may as yet have been unable to accomplish the artificial transmutation of small-pox into cow-pox, nature has methods with which we are unacquainted, but whose results Jenner's great discovery has enabled medical science to utilise. If Mr. Fleming will refer to Warlomont's Manual of Animal Vaccination, he will find more extensive reference to the subject than your columns can admit from,

Yours obediently,

Pall Mall East, S.W., Dec. 1886. ARTHUR HARRIES.

DEATH OF A NIECE OF HARVEY.

To the Editor of THE LANCET.

SIR,—In the obituary column of to-day's newspapers is recorded an event which is suggestive of interest to our profession. "On the 1st inst. at Upp Hall, Braughing, Mrs. Towers, in the ninety-eighth year of her age, the last surviving daughter of the late Admiral Sir Eliab Harvey, of Rolls Park, Essex." In the press and hurry of our day's work, the notice is likely enough to pass unheeded; but that it refers to the last of the seventh generation in direct descent from that prosperous city merchant, Eliab Harvey of London and Chigwell-park, brother of the discoverer of the circulation of the blood, should be enough to claim a moment's attention from anyone who has the slightest reverence for the past. From time to time, outside our special professional life, the public interest is awakened by the overthrow of some fresh pretender to the rightful glory of the immortal physiologist and physician, by the erection of a statue in his native place, by the reverent re-entombment of his remains, or by the publication in facsimile of the note-book in which he himself recorded his observations and his labours. But gratifying as these events may be, they lack the living breathing kinship that the above simple announcement awakens. The deceased lady was the last of nine children of Admiral Sir Eliab Harvey and Lady Louisa, daughter of Earl Nugent. Her three brothers died childless in their father's lifetime, and, in that line at least, with her the name of Harvey ends. How the gallant old admiral, who for forty years fought the battles of his country, and ended by commanding the *Téméraire* at Trafalgar, is duly set forth on the marble tablet in Hempstead Church, where he sleeps with fifty of his kindred. His birth in 1758 takes us back a century ago, and those who are curious in such matters may fill in the steps 'twixt him and his first namesake, if they consult the pedigree of the Harvey family as set forth in Wilson's History of S. Laurence Pountney, London, 1831, at page 228, and the coffin inscriptions in the Harvey vault, lately published in the Miscellanea Genealogica et Heraldica, vol. i., series 2.

I am, Sir, yours faithfully,

W. H. ALLCHIN.

Chandos-street, Cavendish-square, W., Dec. 4th, 1886.

A "NEW" METHOD OF EXCISING THE KNEE-JOINT.

To the Editor of THE LANCET.

SIR,—I see by your report that at the Medical Society on Monday night Mr. Herbert Allingham described as such the method of making a long vertical incision and dividing the patella into two lateral halves. I have twice within the last three or four years shown such a case at the West London Medico-Chirurgical Society, and the method was not new then. Anyone who will refer to my "Index of Surgery," third edition, p. 128, will see it briefly noticed there. I believe the priority of performance of this operation is due to Professor Ollier, and I am certainly of his opinion that it ought to be reserved for cases of injury to the knee-joint. It does not, according to my experience, possess a single one of the advantages which your report states that Mr. Allingham claims for it. On the contrary, it gives comparatively limited and incommodious access to the joint, and especially to its posterior and lateral recesses. In any case which proved, when the joint was opened, to be one in which the bone was very little affected, it would still be impossible, through this perpendicular section, to erase the back of the joint properly without excising much healthy bone, and thus making the prospect of restoration of mobility practically hopeless. Compare with this the plan, originated by Volkmann and adopted by Ollier and others, of opening the joint by transverse division of the patella. Surely no one who has tried both can doubt the superiority of the latter. The quadriceps is no more weakened by one than by the other. There is no ligamentous or fascial structure divided in the operation which cannot be reunited by buried sutures just as effectually as can the patella itself. On the other hand, when the case to be dealt with is one of injury, the indications are quite different, and the longitudinal incision, from its possessing, although in a small degree, the advantages common to all longitudinal incisions as com-

pared with transverse, may be reasonably preferred, for after injury there is no tubercle to be ferreted out of corners, but simply the indication to remove just as much and just as little injured bone as will suffice, and to cleanse the joint of blood and dirt.

I remain, Sir, your obedient servant,

C. B. KEETLEY.

Dec. 1886.

NOTE ON THE EXISTENCE OF IODINE IN THE FREE STATE IN A MINERAL WATER.

To the Editor of THE LANCET.

SIR,—It has been known for many years that the water of the Woodhall Spa, near Lincoln, is exceptionally rich in bromides and iodides. In the course of an investigation recently conducted by me, I have made an observation which appears to be important. I find that there is free iodine in the water—not a mere trace of free iodine, but sufficient to impart to the water a brown colour of considerable depth of tint. The proof of the presence of the free iodine in this water is very striking. There is the formation of the blue iodide of starch when a little starch paste is simply poured into the water. Another very striking characteristic is that when the water is shaken up with one-twentieth of its volume of bisulphuret of carbon it loses its brown colour, whilst the bisulphuret of carbon assumes a pink-violet colour, owing to the solution of iodine by the bisulphuret of carbon. So far as I am aware, this is the first instance in which free iodine has been found in appreciable quantity in a natural water. For many years the Woodhall Spa has been celebrated as a valuable remedy in skin diseases. The fact that it is a solution of free iodine is interesting in this connexion, and is well worthy of the attention of the medical profession.

I am, Sir, yours obediently,

Dec. 15th, 1886. J. ALFRED WANKLYN.

THE TREATMENT OF ALCOHOLISM BY STRYCHNINE.

To the Editor of THE LANCET.

SIR,—*A propos* of your interesting leader on the above subject published in THE LANCET of the 16th ult., I should like to be allowed to make a few passing remarks. The treatment in question, as recommended from theoretical and clinical researches by Luton, Giacomini, Magnus Huss, and other continental *savants* of the medical profession, and now tried by Russian practitioners, notably by Drs. Popoff and Talvinski, was extensively experimented upon, so far back as 1869, by Deputy Surgeon-General F. G. Joynt, who was at the time medical officer in charge of the European General Hospital, Bombay. I am not aware if any other army medical officer followed his method of treatment; but suffice it to say that the drug proved in his hands a sheet-anchor in cases of ebriositas (now termed alcoholism) and delirium tremens. I may *en passant* mention that Dr. Joynt's solution of strychnia was, unlike the British Pharmacopœial preparation, made with dilute nitric acid and a smaller proportion of the alkaloid, and the dose usually exhibited was twenty-four minims two or three times a day.

I am, Sir, yours faithfully,

Aden, Nov. 25th, 1886. A. LYON MERCADO, S.M.D.

ST. ANDREWS UNIVERSITY.

(*From a Correspondent.*)

THE Senatus Academicus of the University of St. Andrews has presented a memorial to the Right Hon. the Secretary of State for Scotland, praying for two additional chairs for its medical faculty—viz., a chair of anatomy and a chair of botany. The St. Andrews Graduates Association are also moving in the same direction. About six weeks ago a deputation appointed by the University had an interview with the Right Hon. the Secretary of State for Scotland and the Right Hon. the Lord Advocate, urging the propriety of augmenting the medical chairs to the extent indicated, by introducing a clause or clauses to that effect into the forthcoming "Universities (Scotland) Bill." St. Andrews has always felt the necessity of increasing its teaching medical staff, and attempts have been made from time to time in this direction for very many years past. The present seems a favourable opportunity for attaining the desired end. The University is desirous of increasing its teaching staff to enable it to give two *anni medici*, the period of residence required for medical graduation at the Scottish universities. With two additional medical chairs, St. Andrews would not only be able to give the first two years of the medical curriculum, but it would be enabled to draw upon the Extra Academical and Hospital Schools of the United Kingdom for the last two years, an arrangement which could not fail to be very convenient to many aiming at a university medical degree. St. Andrews has now a seat at the General Council of Medical Education and Registration of the United Kingdom, and is splendidly equipped as regards the teaching of chemistry, physiology, and zoology. It has also a very fine medical library and museum, and the amenities of St. Andrews as a place of study are everywhere recognised. Of late years St. Andrews has made great strides in science teaching, and if it only succeeds, by public or private endowment, in obtaining its present quest, it may in the future become as well known for its medical teaching as it has in the past been for its divinity and arts teaching.

LIVERPOOL.

(*From our own Correspondent.*)

THE MEDICAL INSTITUTION AND THE HOSPITAL INQUIRY COMMITTEE.

THE special general meeting of the members of the Medical Institution, which was held on the 3rd inst., to receive the report of the Hospital Inquiry Committee, was largely attended, there being more than a hundred gentlemen present. The President (Dr. Nevins) was in the chair. The report was read by Dr. Wm. Alexander, the secretary to the Committee, and was listened to with the deepest interest by all present, each of whom was furnished with a printed copy of the report. At its conclusion the adoption of the report and a vote of thanks to the Committee were moved by Mr. McCheane, consulting surgeon to the Lock Hospital, and a former president of the institution. This was seconded by Mr. C. B. Wilson, consulting surgeon to the Lying-in Hospital, and after some discussion it was carried by a large majority. Dr. Imlach spoke at considerable length, and as some of his statements were repeated in a letter which he addressed to the President of the Hospital for Women (a copy of which appeared in THE LANCET of the 11th inst.) it appears desirable to notice some points in detail. Dr. Cameron's reason for resigning his seat on the Committee was a purely personal one. He had been called in consultation with Dr. Glynn to see Dr. Imlach when the latter was dangerously ill, and expressed an opinion that the inquiry should not proceed; but as this did not meet with the views of the other members of the Committee he resigned his seat. Mr. Bickersteth's reason for ceasing to attend was because he found himself quite unable to devote the time which he considered necessary to so important an inquiry. The primary object of the Committee was not to prepare a scientific report for the profession, but a report on the management of the Hospital for Women to the Medical Institution. The Committee were only asked to go into the cases which were the subject of operations during the year 1885. Between the early summer and the month of October the Committee held no meeting on account of the trial of Casey *v.* Imlach. The only thing done by the Committee was to request information from medical practitioners as to cases which they had seen of patients who had come under their care before and after being patients of the hospital. This information was given quite impartially and in confidence. That it could have had any prejudice against Dr. Imlach in the trial was disproved by the jury giving a verdict in his favour, without waiting for the judge's summing up. The general opinion of the profession here is that the report is a most admirable one, being exhaustive, fair, impartial, and most moderate. Too much praise cannot be given to the members of the Committee for their prolonged and self-denying devotion to the extremely invidious duty cast upon them.

DEATH OF DR. RICHARD JOHN LUPTON.

This gentleman, whose death was noticed in last week's LANCET, will be well remembered by many an old fellow-student. He commenced his medical studies in 1860 at the Liverpool Royal Infirmary School of Medicine, where he studied for three years, becoming subsequently a student at University College, London, and at Aberdeen, where he graduated with honours. He returned to Liverpool in 1866, and commenced practice in the neighbourhood wherein he resided until his death. He held office formerly as honorary assistant surgeon to the Ladies' Charity and Lying-in Hospital, and at the time of his death was one of the honorary medical officers of the Hospital for Women. For the vacancy thus created there are already many candidates.

THE ROYAL INFIRMARY.

At a special general meeting of the trustees just held, Dr. Waters was elected consulting physician to the Royal Infirmary, having recently resigned the office of physician; and to the vacancy thus created Dr. Richard Caton, physician to the Northern Hospital, was elected without opposition. Dr. Waters is well and favourably known as an authority on chest diseases, and it is hoped that he has many years of useful work before him.

LOCAL HOSPITAL CHANGES.

At the Northern Hospital there is a vacancy for a physician, in place of Dr. Caton, appointed to the infirmary, and Dr. James Barr is a candidate. At the Stanley Hospital there are vacancies for a physician and a surgeon, owing to the resignation of Dr. Costine and Mr. Sheldon, who have each held office for the full period of twenty years. For these vacancies Dr. Whitford and Mr. Robert Jones are already candidates, and others will probably be forthcoming.

Liverpool, Dec. 15th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

GATESHEAD WORKHOUSE CHILDREN'S HOSPITAL.

MR. KNOLLYS, the Local Government Board Inspector for the district, has made some serious statements as to the condition of the children in the hospital of the workhouse at Gateshead. The statements have excited much public attention, and our local press has been also much occupied with the matter. Mr. Knollys says that on the occasion of his visit to the hospital he found twenty-eight boys and girls, ranging from thirteen years of age downwards, all suffering from some disease of the skin. It is practically impossible, from the structure of the building, to keep the sexes separate; that the floor was damp, and the underclothing on the beds was rendered foul by discharge; that on the day of his visit twenty-two out of twenty-eight children slept two in a bed; that the pillows were dirty, and that the sheets were little better than a patchwork of rags; that the straw of the beds actually came in contact with the skin of the little patients, which from the nature of their diseases was naturally tender; that four or six, and on one occasion eight, boys had washed in the same water; that eight or nine, and on one occasion only four, towels had been used for drying the skins of twenty-seven children; that in one room he found a woman suffering from a syphilitic disorder, that three children suffering from measles were in the same room, and that the room, which could not be ventilated as it should be, had a most offensive smell. He further stated that he had again and again complained of the dirty and uncared-for appearance of the children in the building. Mr. Knollys made also suggestions to the guardians that a competent nurse should be appointed instead of the present pauper nurse, and that the building be no further used for its present purpose. The guardians have been highly indignant at Mr. Knollys' charges, some of which they have denied, but some of the minor ones have been admitted. Some of the more indignant guardians admitted that they had not visited the hospital in question. Dr. Cook, the medical officer of the workhouse, explained that the wooden building condemned by the inspector was intended only to last ten years, and was only regarded as a temporary building for the reception of patients during the fever epidemic which existed when it was erected. The number in the house had increased, but the accommodation had not increased in proportion. Dr. Cook further explained that the accommodation he had formerly at the "house" for isolation purposes had been taken from him, and he had to take on himself responsibilities which he did not feel justified in taking. He had to use the best means he had at hand, and to take into the hospital a number of cases suffering from very infectious ailments of the eye. The hospital was full, and he had no means of isolating disease. The feeling here is that a state of things such as described by the inspector and their own medical officer is not creditable to the intelligence, to say nothing of the humanity, of the guardians of an important and wealthy borough like Gateshead.

NEWCASTLE HOSPITAL SUNDAY.

The returns on Hospital Sunday and Saturday collections continue to show a decided improvement on last year's. The fourth list shows that £2000 12*s.* 9*d.* has been received from places of worship, as against £1898 last year. From workshops £1580, as against £1231 last year. This improvement is all the more gratifying taking into account that many of our industries are far from busy this winter.

SCARBOROUGH HOSPITAL.

The report of the house-surgeon, Dr. Kenneth Frazer, shows that during the month of November he made 1075 visits to patients' houses in connexion with dispensary work. There has been an epidemic of measles in the district, I believe.

NEWCASTLE INFIRMARY.

In view of the financial position of the Newcastle Infirmary, a special committee has been appointed to take evidence, and the public is invited to take part in the matter and to offer any evidence likely to conduce to the object in view—namely, the placing of the institution in a more satisfactory financial position.

Newcastle-on-Tyne, Dec. 13th.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THOSE candidates who failed in one subject only at the recent First and Second Professional Examinations will be permitted to take out lectures and hospital practice this year and go up in July next for the examination they missed. Those who fail in more than one subject lose an entire year of their medical studies, and no credit will be given for hospital and lectures taken out. There will be a supplemental examination for the Third Professional Examination, but not for the First and Second, and candidates who are allowed in for examination will pay, instead of three guineas for re-examination, a fee of eight guineas. At present there are three lady students attending the lectures on Chemistry now being delivered by Sir Charles Cameron at the Medical School of the College. There will be two candidates for the Vice-Presidency of the College at the election in June next—viz., Mr. Henry Fitzgibbon and Mr. H. Gray Croly, both being visiting surgeons to the City of Dublin Hospital.

THE EPIDEMIC OF ENTERIC FEVER IN CORK.

Although the epidemic of fever recently referred to in these columns may mainly be attributed to the defective sanitary condition of the town, yet undoubtedly the water-supply is not all that could be desired. For example, at Macroom the sewer matter is discharged into the river from which the supply of water for the citizens is obtained, and no doubt there are other possible sources of pollution. At the suggestion of the public analyst monthly analyses of the water will be made for the future, as is the practice in all large cities. During November over seventy cases of enteric fever were under treatment in the hospitals or by the various dispensary medical officers, with a mortality of about 3 per cent.

THE SANITARY CONDITION OF THE DUBLIN BARRACKS.

On several occasions attention has been drawn to the alleged insanitary condition of some of the Dublin barracks, more particularly the Royal Barracks; and it was a matter of surprise, considering the number of deaths from enteric

fever occurring in the latter institution, that a thorough investigation was not at once ordered by the military authorities. At last, however, they appear to have awakened from their lethargy, and I am informed that the Commander-in-Chief has appointed a commission to investigate and report on the subject. Grave doubts have existed for years as to the sanitary state of the Royal Barracks, and the commission, by a thorough overhauling of the sewerage arrangements, will carry out an investigation, which is urgently required.

MUSCULAR ANOMALY.

There is at present in the dissecting-room of the Ledwich School of Medicine an example of the biceps flexor cubiti taking its origin by three heads instead of two, so that it might be designated an anterior triceps. The third head came off close to the insertion of the lower part of the coraco-brachialis muscle, on its outer aspect, and passed to the posterior part of the muscle. Each head was well defined. This anomaly I believe to be extremely rare.

Dublin, Dec. 14th.

BELFAST.

(From our own Correspondent.)

THE VACANT SENATORSHIP OF THE ROYAL UNIVERSITY.

A LARGE number of the northern graduates, who are Presbyterians, had agreed to support the candidature of Professor O'Sullivan of Cork, as they believed that Cork should get a share of the representation on the Senate of the Royal University, and, further, as the vacancy was caused by the death of the Rev. Dr. Kavanagh, they thought that it was but just that another member of the Catholic body should be elected. However, owing to the recent action of the Government in appointing Dr. O'Dyer, the Catholic Bishop of Limerick, a senator of the Royal University in room of the late Dr. Fleming Stevenson, a leading Presbyterian, the coming contest has assumed a new phase. The members of the Presbyterian Church consider they had a hereditary right to Dr. Stevenson's seat, and they urged the Lord-Lieutenant to appoint Dr. Todd-Martin, a very distinguished graduate of the late Queen's University. As this recommendation has not been attended to, it is feared by many that Professor O'Sullivan may at the eleventh hour lose his expected northern support.

THE LAGAN NUISANCE.

At the present time a great deal of discussion is taking place, both in the public press and in private circles, in reference to the Lagan nuisance. This river is always greatly polluted by receiving the abominable Blackstaff, as well as many other sewers, and at certain times of the year, especially in summer, the smell arising from it is simply intolerable. The Town Council propose building two main sewers, one on each side of the Lagan, which would intercept all the various drains which now open into that river as well as into the Blackstaff, and which are planned to discharge their contents in deep water far beyond the harbour. Further, it is arranged to narrow and deepen the channel of the Lagan and to construct substantial banks. A section of the public are supporting another scheme, which aims at purifying the river by the construction of locks. By this plan the present offensive mud-banks would be placed permanently under water, thus rendering them innocuous; an ornamental pond suitable for boating would be formed; and the flow of the Lagan would be used to increase the velocity, dilute, and direct the flow of the Blackstaff and sewers at present discharging above the Albert Bridge, so that the sewage would be carried out to sea and not returned by the flow tide. It is satisfactory to find that public opinion is being aroused to the necessity of having this terrible nuisance abated.

THE ROYAL HOSPITAL.

As the financial condition of this charity is again in an unsatisfactory state, it has been suggested that, in commemoration of the Queen's Jubilee, a sum of money should be subscribed, the interest of which could be devoted to this institution; and a very energetic member of the board of management writes to the press advising that the hospital should be removed to the place where the old charitable society is at present located. This would be a most desirable change, as there is a grave suspicion that the hospital is placed in anything but a good sanitary situation, and its present size is not adequate to the requirements of such a rapidly increasing town as Belfast. During the present session there are 130 students receiving clinical instruction, while last winter there were 162. The appointment of a new matron took place on Saturday, when Miss Isbitt (Canterbury) was unanimously chosen out of twenty-six candidates.

LISBURN DISPENSARY.

At a meeting of the Committee of the Lisburn Dispensary district held on Monday, Dr. James Jefferson, the brother of the late medical officer of the district, was appointed dispensary doctor. The salary of the late Dr. John Jefferson was £100 per annum, but the Lisburn Board of Guardians decided, in view of the present agricultural depression, to reduce the income to £80, and at this salary Dr. Jefferson was elected.

DEATH BY SUFFOCATION.

Two women, mother and daughter, were found dead in a house in Belfast on Monday. The discovery was made by another daughter who slept with them, and who was so overcome that she did not awake until twelve o'clock, seven hours after her usual time. On the police being informed, they searched the house, and found a quantity of smouldering cinders in a vessel under the bed. The vapour from this vessel in a small and badly ventilated room is supposed to have suffocated the women, although there is a supposition that the deceased may have been injured by eating tinned meat, which, it is said, constituted the supper.

Belfast, Dec. 7th.

PARIS.

(From our own Correspondent.)

PROFESSOR PETER'S INAUGURAL LECTURE.

ON Dec. 8th Professor Peter delivered his first lecture on Clinical Medicine at the Hôpital Necker before a crowded audience, composed of students and practitioners, selecting "The Clinical Aspect of Contemporary Medical Doctrines" as his subject. Sixty-seven years ago, said the lecturer, a weak, shy, and sickly man, alone in the hospital, without assistants or appliances, made a discovery that was to revolutionise the medical world. The man was Laennec; the discovery, mediate auscultation. Mediate percussion had been discovered towards the middle of the previous century by Avenbrugger, but it has passed unnoticed except for a curt mention by Stoll and Van Swieten, and remained unknown until the treatise of the Viennese physician was translated and commented on by Corvisart. Corvisart, the pupil of Avenbrugger and Morgagni, was the teacher of Laennec, and bent his mind in the direction of his subsequent inquiries, to which inquiries the medicine of today owes much of its precision. But precision in medicine is only possible for the recognition of the accomplished fact—that is, the physical change in living matter, the lesion and its signs. The *morbid act*, disease in its evolution, escapes precision; for the act, which is the *to become* is subordinate to the vitality of the affected organism, dependent upon the forces of the organism, and, like these forces, infinitely variable. Laennec definitely introduced into medicine pathological anatomy and semeiology, and showed the relationship between the symptoms and the lesion. He taught us to be localisers. To take, for example, pneumonia. The old doctrine of *febris peri-pneumonica* was set aside, and inflammation of the lung is treated as a local disease, of which the accompanying pyrexia is only a symptom. The *disease* in its pathological anatomy and physical signs is discussed at length, but the *patient*, as revealed in the general symptoms and the type of the malady, comes in for but scant consideration. From the stethoscope of Laennec have sprung numerous other instruments of precision; and thus we have the opthalmoscope, the laryngoscope, the otoscope, and the microscope, which, together with chemical analysis, enable us to make the necropsy, as it were, of the living body. From precision to prelesion, in the diseased organs we have sought the diseased tissue, and in the tissue the morbid element. It might have been thought that beyond this there was nothing, but this were to reckon without the microbe, the

universal cause of parasitic disease. For the new school the microbe *is* not the lesion, but its agent. For instance, pneumonia, the local inflammation of the lungs, is produced by the pneumococcus, but the pathogenic agent can only accomplish its mission by infecting the organism. Thus we have the work of Laennec upset by his followers, localisation *à outrance* leading to generalisation; and thus the histologists, become parasitists, have returned to the old idea of pneumonia, a general disease. The lecturer reminded his hearers that he had professed this opinion seventeen years ago, and that he had said in his clinical lectures, "The lesion is to the tissue what the symptoms are to the forces. The fever is the disease, of which the lung affection is a consequence; and as the type of the fever, whether inflammatory, nervous, or bilious, &c., varied, so should the treatment. We have not to do with pneumonias, but with pneumonic patients." M. Peter then alluded to Virchow's magnificent conceptions in cellular pathology, and his explanation of heterologous formations by heterochronism and heterotopism, and the final overthrow of these views by the discovery of the bacillus. For a time Koch was triumphant, but the supreme reign of the bacillus has not been long. It has been shown that the extent of the disease does not coincide with the quantity of the bacilli, and the partisans of these microorganisms now say, "It is not the bacillus that makes the disease, it causes it only indirectly by the secretion of a ptomaine." At the present time the whole of pathology is dominated by pathogeny, and this by bacteriology. Bacteria here, bacteria there, bacteria everywhere. Every day we learn with stupefaction that yet another disease is parasitical. As with pneumonia, so with rheumatism and malignant pustule. There are bacteria in the saliva, which are useful in the mouth, but morbiferous in the lungs, where they manufacture pneumonia. There are bacteria to make us feverish in typhoid, others to produce algidity in cholera; some blow hot, others cold. The lecturer passed on to the consideration of the treatments which these views have suggested, some considering that in typhoid the microbe gives rise to fermentation, and this to pyrexia Hence the system of treatment by cold baths, which, although irrational as a general practice, has its applications in certain cases. It is the recognition of suitable cases, which we have learnt from the exclusive practice of Brandt, that forms a real progress. Others, always with an eye to the destruction of the morbiferous microbe, would make injections into the lung without considering that, if even one microbe alone were to escape, it would quickly reinfect the organism by its reproduction. We have learnt, however, that our patients have often a far greater power of resistance than might be imagined. A third therapeutic attempt was prompted by the observation that the cholera bacillus did not reproduce itself in a dry medium, and Koch in consequence advised the people of Marseilles to abstain from watering their streets. The microbic theories have led to attempts of medical antisepsis, but this, although well meant, is chimerical. In surgery the case is different. The patient is supposed to be a healthy man who has received an accidental injury; but in medicine disease already exists, and the enemy is in the stronghold. The anti-rabic inoculations are as well meant, but no less chimerical. Irrational in principle, they are inefficacious in practice. They are irrational, inasmuch as they are supposed, contrary to experience, to prevent the development of a disease in incubation, and holding the organism in its power. Vaccine has not this power over incubating variola, and when we seek to prevent the development of variola in an organism in which it is incubating by vaccination, we find that both appear at their appointed time and run their course simultaneously. These so-called anti-rabic inoculations, after having been proclaimed with *éclat*, have failed lamentably. The mortality has been the same in France this year, as in average years namely, thirty deaths from hydrophobia, fourteen of which occurred in persons having undergone the preservative inoculations. Pathogeny, said M. Peter, in conclusion, is the romance of disease, and pathology is its general history. Study at the bedside teaches us the special history of the patient, and although our flights are less high than in questions of pathogeny, they are more fruitful.

THE FASTING MEN.

Since the appearance of my last letter on Merlatti my sphygmographic records have met with less favour. The last time I offered to take a tracing of Merlatti's pulse it was pointed out to me that he was in a condition of irritability, which rendered the proposed examination undesirable. Contrary to my anticipations, the fiftieth day of the fast has been attained without serious accident. Yesterday there was some congestion about the head, which terminated with epistaxis. Merlatti is to break his fast at a public banquet to be held this evening. As to Succi, he has got half way through his allotted period, and does not appear to be any the worse for his abstinence.

TRANSPLANTATION.

M. Dubousquet recently related a case at the Biological Society in which he had used grafts from the epidermis of a frog to heal the ulcers resulting from severe burns on the foot caused by molten metal. For the sake of comparison one ulcer was treated with grafts taken from the patient's own skin, the other from that of the frog. In both cases four cuttings were applied, about the size of a half-franc piece each. Cicatrisation took place more rapidly in the ulcer treated with the skin of the frog, and the scar is more supple than the other.

HYDROCARBONS IN HYPODERMIC INJECTION.

Dr. Albin Meunier has made a communication to the Société des Sciences Médicales of Lyons, to which the *Semaine Médicale* calls attention, on the use of vaseline as a vehicle for the hypodermic injection of different essences. Eucalyptol, menthol, essence of cubebs, of sandal, of copaiba, and other substances may be so administered, without untoward symptoms. It is said that these injections give rise to no local troubles and very little pain. For the drugs mentioned one part in five of vaseline is used after filtration repeated three times. For thymol the proportion is one in ten. It has also been found that vaseline dissolves creasote, iodine, camphor, sulphide of carbon, carbolic acid, iodoform (when in previous solution with the essences), and even the alkaloids. For some of these the quantities given are as follows: iodoform, one to eighty; sulphide of carbon, one to fifteen; creasote, one to twenty; iodine, one to twenty; cocaine, one to fifty; digitaline, one to a thousand.

Paris, Dec. 15th.

EGYPT.

(From our own Correspondent.)

COCAINE FOR MORPHIOMANIA.

Two cases have recently been observed in Cairo of temporary hallucinations after prolonged subcutaneous use of cocaine, as recommended for abuse of morphia injections. The second case occurred in the person of a European doctor, and only lasted two days, during which it was believed that some harmless servants were persecuting him. It now appears that he was accustomed to take morphia injections himself, and was invited to take charge of the first case during his temporary restraint. This first case has been reported by a Greek, Dr. Comanos, in the *Berliner Klin. Wochenschrift* (No. 38), who watched the patient throughout. After being addicted to the morphia habit for several years he recommended his patient, a middle-aged European of excitable temperament, to take as a substitute three-quarters of a grain of cocaine, hypodermically, three times a day. The pain and distress occasioned by the lack of morphia were relieved by this, but the patient gradually and privately increased the dose until he took every day eight and even twelve grains. This induced great mental irritability, singing in the ears, dyspnœa, and hallucinations, which all disappeared upon returning to injections of morphia. But, unfortunately, a painful attack of herpes zoster ensued, and the patient doubled his former cocaine injections to sixteen and afterwards twenty-three grains a day. The symptoms produced by these large doses were trembling of the limbs, lassitude, incontinence of urine, loss of sleep and appetite, excitement, hallucinations, injected conjunctivæ, and a very fixed expression. He believed that burglars lurked in his garden, and he fired revolver shots at imaginary figures by night, eventually nearly strangling one of his servants because he believed he had swallowed a lantern. He was then removed to a hospital, and, on being searched, cocaine, morphia, and many hypodermic syringes were found on him. His drug treatment consisted of three-

quarters of a grain of morphia subcutaneously injected three times a day, and in forty-eight hours he was perfectly sane again, and prepared to explain away his hallucinations, especially those of sight and smell.

KASR-EL-AINI HOSPITAL.

The out-patient department, which has been taken over by Dr. Sandwith, continues to supply many interesting cases to the hospital, including those requiring surgical interference, in which the natives have great faith. During the last week, Dr. Milton removed a mass of strumous glands from the neck, excised a portion of the tunica vaginalis for chronic hydrocele, and amputated a breast for a fungating lobular tumour, which protruded entirely outside the skin. These cases were dressed with corrosive sublimate lotion, oiled paper next the wound, and then dry cotton-wool and bandage outside. Many cases of union by first intention have followed this simple dressing, and one of the cases shown to the students was a boy whose knee had been excised for strumous disease, and afterwards dressed in this way. Primary union followed, and in a fortnight the boy was on crutches, with his diseased leg kept off the ground by a high heel on the other foot. The following three operations have been done during the week by the native surgeons. A median perineal lithotomy in a man with chronic bladder disease, but without bilharzia; a supra-pubic lithotomy for a stone weighing 4½ oz., this being the fourth similar operation which has lately been done by the same surgeon; and the removal of elephantiasis of the scrotum which had followed on an old urinary fistula. Upon the same day a long Guinea worm was extracted from the leg of a native who had lived some years in the Soudan, and stated that similar worms were common there, and often appeared near the genital parts of women. A Guinea worm had been extracted slowly from his other leg last year, but on the present occasion the whole worm was found lying coiled up in the cyst of a chronic fistulous tract. These worms are rare in Egypt.

EXPLOSION OF A SHELL.

Two days ago three British soldiers found an unexploded Krupp shell in the desert, and took it to the armourers' shop in barracks to see what was inside it. It will hardly be believed that they placed it in an anvil and struck it with a sledge-hammer, when it at once burst. One man's skull was badly fractured, with brain protruding, and he died instantly; another also died at once, having received a portion of the shell in his abdomen; and the third required amputation of one arm and one hip-joint, and died during the day. An unfortunate corporal, walking near, lost half his forearm; and a fifth man was bruised in the leg by a bit of the shell, which whistled by him. There are many stories of soldiers using heavy shells as garden-rollers and garden ornaments; and once, after the battle of Tel-el-Kebir, of men being found lighting a fire with a pile of shells to form the hearth.

Cairo, Oct. 29th.

ROYAL COLLEGE OF PHYSICIANS.

A COMITIA of the Fellows was held on Thursday, the 16th inst., Sir W. Jenner, Bart., President, in the chair. The copies of Harvey's "Prælectiones," suitably bound for presentation to Her Majesty the Queen and to His Royal Highness the Prince of Wales, were laid on the table by the President.

A communication from the General Medical Council respecting the length of the curriculum was referred to the Committee of Management. A report from this Committee was adopted.

The report of the Committee of Delegates (see page 1194) appointed by the Royal College of Physicians and the Royal College of Surgeons, to consider the desirability and practicability of granting degrees in medicine and surgery to persons who have passed the Conjoint Examinations of the two Colleges, was presented. Its adoption was moved by Dr. Wilson Fox and seconded by Dr. Handfield Jones. Dr. Allchin moved, and Dr. Norman Moore seconded, an amendment, stating that no scheme shall be deemed satisfactory unless it provide for the conferring of degrees by some University body outside the Colleges themselves, but on which they could be represented. Sir W. Gull urged that the degrees should be confined to clinical medicine and surgery, and he subsequently moved an amendment to that effect. Drs. Curnow, Wilson Fox, Chambers, and Quain also spoke, when the debate was adjourned on the motion of Sir H. Pitman, seconded by Sir G. Paget.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an extraordinary meeting of the Council of the above College, held on Thursday, the 16th inst., a report from the Delegates of the two Colleges on the expediency of granting the title of Doctor to the holders of the diplomas of the two Colleges was received. After a lengthened discussion certain verbal alterations were suggested, and the report was referred back for the further consideration of the Delegates.

Obituary.

NORMAN CHEVERS, C.I.E., M.D., F.R.C.S.,

DEPUTY SURGEON-GENERAL, BENGAL MEDICAL SERVICE.

ON Tuesday, Dec. 7th, 1886, a number of Indian medical officers, with other friends, assembled at Kensal-green to pay the last tribute of respect to a much-valued and deeply regretted brother officer, whose sudden and unexpected death (from cardiac failure) on Dec. 2nd had caused profound sorrow and surprise; for to observers generally he seemed but quite lately to be in good health, with the prospect of continuance of his valuable life for many years to come. Though he had not lived to attain the allotted duration of human life, having only reached his sixty-eighth year, Norman Chevers lived long enough to do work of an enduring nature such as falls to the lot of few to accomplish, whilst the tenour of his whole career has been, to those who knew him well, a striking illustration of a life lived and ruled by the highest principles. His was, indeed, a blameless and noble life—one in which commanding intellect and vast stores of learning of many and varied aspects were devoted to the advancement of knowledge, the relief of suffering, and the welfare of his fellow-men, especially of those of the great Indian Empire, in which his lot had been cast, his best work done, and his well-merited reputation acquired.

His early career, before proceeding to India in 1848, has been referred to by one who knew him well. He had even then acquired a marked reputation in pathology and medicine, and when he arrived in Bengal was somewhat older than was usual with newly-joined medical officers; but his matured powers and already large experience were soon brought into requisition for the duties of civil medical charge of the important stations of Chittagong and Howrah, and ere long in the very onerous and responsible post of secretary to the Bengal Medical Department. How well those duties were performed was shown by the fact that throughout the whole of the trying time of the Mutiny, when the medical, like other departments, was submitted to great strain, no failure took place in the Medical Department, which was administered by Forsyth and Chevers. But it was during his tenure of the important offices of officiating Inspector-General of Gaols, member of the Senate of Calcutta University, and in that of Principal of the Medical College of Bengal and Professor of Medicine, that the writer of this memoir became really acquainted and continually associated with him during many years of intimate co-operation as colleagues in those institutions, and thus had full opportunity of knowing the great worth and manifold excellencies of the accomplished medical officer whose loss is now deplored.

To no one is the British or native soldier, or the civil population generally, more indebted than to Chevers for the light he has thrown on, and the practical instructions he has laid down for guidance in reference to, those great sanitary

questions which so materially influence the health, and consequently the well-being, of all in India.

His able administration of the Medical College raised it to a high standard of efficiency; his teaching of medicine, hygiene, and other cognate subjects was of the greatest public benefit; whilst his writings are regarded as authority of the highest repute: such, for example, are his "Preservation of Health of Soldiers in India"; his "Removable and Mitigable causes of Death"; his great work on "Medical Jurisprudence in India," which won for him the Swiney Prize; that on "Diseases of the Pulmonary Artery" also his many admirable lectures and monographs on subjects directly or indirectly connected with public health; lastly, his work on Indian Diseases, which was completed only just before his lamented death. But it was not in medicine only that his powers were manifested; his acquaintance with literature, archæology, history, and art were equally remarkable, and delighted the friends with whom he conversed, an additional charm being communicated by the keen sense of humour which often found vent in the course of even his most impressive utterances. A fluent and graceful speaker, his addresses always attracted attention, and left a deep impression on those who heard them; no one could be long with him without feeling the influence of his well-stored and highly cultivated mind. But all this was perhaps the least attractive side of his character. It was the simple, loyal, chivalrous nature which charmed. He was incapable of anything mean. In all senses in which the word can be applied he was a gentleman. All he did was directed by a high sense of principle and honour. If he erred, it was not from lack of these guides; it might have been from an overestimate of their claims. He did what he thought was right, guided by that which to him was the highest light, and few men have come nearer to the mark aimed at than he did!

Chevers retired from the service in 1876 with the rank of Deputy Surgeon-General, and it was not until 1881 that Government, in recognition of his services, conferred on him the dignity of Companion of the Indian Empire. His labours were not, however, completed, for he was doing much good work up to the last; and he was making notes but a few hours before he died.

As President of the Epidemiological Society, he rendered further service to the subjects of epidemiology and disease, whilst his lectures and addresses on matters connected with sanitary science all betoken the unceasing interest and mental activity he continued to devote to these subjects. The crowning work of his life was his important "Treatise on Disease in India"—a book of great value, containing a comprehensive view of the whole subject of Indian disease. Other and fuller details of all he did, of the books he wrote, the appointments he filled, and the honours he held, will doubtless be given; it is needless, therefore, to dilate on them here, in a mere passing tribute to his worth, by one of many who knew him well and honoured him greatly. His memory will long be cherished, both in his service here and in the East, with affection and respect, and his name will live in their annals as a benefactor of India, and as one of the brightest ornaments of the old Indian Medical Service.

Medical News.

UNIVERSITY OF DURHAM.—At the recent examinations for degrees in Medicine and Surgery the following candidates satisfied the examiners:—

DOCTOR IN MEDICINE, FOR PRACTITIONERS OF FIFTEEN YEARS' STANDING.

Deans, John, M.R.C.S., L.S.A.
Denziloe, W. Le Gros, M.R.C.S., L.S.A., M.R.C.P. Ed.
Hardyman, C. E., F.R.C.S. Ed., L.S.A.
Hedley, John, M.R.C.S., L.S.A.
Smith, T. S., L.R.C.S. Ed., L.S.A.
Wood, T. Outterson, F.R.C.S.Ed., F.R.C.P. Ed.

DOCTOR IN MEDICINE (Essay).

Dixon, H. W., M.B., L.R.C.S.Ed.
Richards, G. W., M.B., M.R.C.S.
Rumboll, C. F., M.B., M.R.C.S.
Slater, W., M.B., L.R.C.S. Ed.

The Gold Medal for the best essay for the year 1886 was awarded to John Valentine Salvage, M.B., L.R.C.P., M.R.C.S.

BACHELOR IN MEDICINE.

Abbot-Anderson, W. Maurice.
Arnison, William Drewett.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentlemen, having passed the Fourth and Final Examination for the Letters Testimonial under the new scheme, have been admitted Licentiates:—

Samuel Boake, Patrick Thomas Bolger, Thomas N. Frood, William A. Kelly, Samson Hops Newland, Everard M. Power, Michael Lane Riordan, William John Scott, Thomas H. Strangman, William Joseph Taylor, Percival J. W. Ternan, and John Toppin.

The undermentioned gentlemen, having passed their Final Examination under the old scheme regulation, have been admitted Licentiates of the College:—

James H. Atkin, Thomas Bertram, James Butler, George J. Burke, Eugene Byrne, Patrick Carney, Charles Casey, Norbert Durrant, Richard L. Fitzgerald, Thomas Keough, James Joseph McGrath, Patrick Joseph Power, Edmund B. Russell, and Charles James Rutledge.

BEQUEST.—Mr. John Hunt has left £500 to the Adelaide Hospital, Dublin.

THE Hospital Saturday collection at Nottingham has been fixed for the 29th prox.

IT has been decided to hold on the 18th inst. a Hospital Saturday collection in aid of the Ilkeston Cottage Hospital.

PLANS have been accepted for the proposed General Hospital for Merthyr. The subscriptions and donations already promised amount to £3900.

VACCINATION GRANT.—Mr. R. Istance, Risca district, Newport (Mon.) Union, has received the Government grant for efficient vaccination in his district (seventh time).

SEAMEN'S HOSPITAL SOCIETY.—Sir Andrew Clark, Bart., M.D., will preside at the sixty-seventh annual court of this Society, to be held in February next.

AT a well-attended meeting of the Maidstone branch of the Kent Volunteer Medical Association recently held, it was unanimously resolved that the corps be put into uniform at once.

THE bazaar which was recently held at Manchester in aid of the extension fund of St. Mary's Hospital proved a gratifying success, a net sum of £420 having been paid to the account of the institution.

THE amount of the proceeds of Hospital Saturday, held a few weeks ago in Torquay and the neighbourhood, on behalf of the Torbay Hospital, has been ascertained to be £83.

ONE of the conductors of stores in the commissariat and transport corps has been poisoned by swallowing cyanide of potassium in mistake, as is supposed, for gin. The drug was kept, it seems, for the purpose of cleaning gold lace.

AT a meeting on the 14th inst. of the City Commission of Sewers, instructions were given that the Streets Committee report without delay on the subject of sinking artesian wells in the City with a view to supplying the inhabitants with water.

NEW GENERAL HOSPITAL FOR BOMBAY.—We understand that the Government of Bombay have just sanctioned the expenditure of ten lakhs of rupees for the erection of a new General Hospital for that city on the site of Fort St. George, recently demolished.

HOSPITAL SATURDAY AT WOLVERHAMPTON.—Last Saturday the collection for the Wolverhampton and Staffordshire General Hospital realised £1514 11*s.* 7*d.*; for the Eye Infirmary, £224.

THE COUNTESS OF DUFFERIN'S FUND.—The receipts in the Bombay Presidency towards this fund amounts now to 64,616 rupees, a sum large enough to indicate that the movement is gaining upon public sympathy and support.

ON the 8th inst., in consequence of the prevalence of rabies in the borough, the watch committee of the Nottingham town council passed regulations for the muzzling of dogs and the destruction of stray dogs and such as were not muzzled.

EIGHTEEN female medical students have been expelled from St. Petersburg for taking part in a meeting which had been forbidden by the police. The female medical school has long been considered a nursery of nihilists, and attempts have been made to close it altogether.

PERTHSHIRE MEDICAL ASSOCIATION.—The monthly meeting of this Association took place in the directors' room in the infirmary on Dec. 3rd. Dr. J. P. Bramwell, Perth, read a paper on "Hyper-arterial Tension," the discussion of which was adjourned till the next meeting.

SMALL-POX IN JAMAICA.—Advices received at Plymouth on the 12th inst. from the West Indies report that small-pox is raging furiously in Jamaica. On the departure of the mail there had been 1000 cases and 100 deaths, and 500 patients were under treatment.

THE PHARMACY ACT.—The Pharmaceutical Society of Great Britain on the 15th inst. obtained a verdict for £10 claimed as penalties from a person who had sold laudanum, and called himself a druggist when he was not registered as such, contrary to the provisions of the Pharmacy Act.

AT the final meeting of the Committee of the Exeter Hospital Saturday Fund on the 11th inst., it was reported that the total amount received was £471. The next collection will be held in the summer of next year, about the time of the celebration of the Queen's Jubilee.

CHOLERA IN CALCUTTA.—We learn from an Indian contemporary that cholera has been epidemic in Calcutta. During the week ending October 30th there were registered 73 deaths, against 63 and 98 in the preceding two weeks. The number, we learn, is higher than the average of the past quinquennium by 49. Recent advices, however, report a diminution of the outbreak.

INTERNATIONAL HEALTH CONGRESS.—This congress, which is to be held in Vienna in September of next year, promises to be successful. The Hereditary Prince of Austria, Crown Prince Rudolphus, has consented to act as the patron of the congress, and the Chief of the Cabinet, Count Traffe, has been chosen as honorary president. The committee, with Hofrath Schneider at its head, is working energetically.

POISONED BY TINNED SALMON.—Three members of a family at Great Bowden, having last week partaken of tinned salmon for supper, symptoms of poisoning were soon afterwards manifested, all being seized with cramp and vomiting. Dr. Lee, of Market Harborough, was summoned, and antidotes were administered, and the sufferers were eventually relieved. A cat, to which a small portion of the salmon was given, showed like symptoms.

DORSET COUNTY LUNATIC ASYLUM.—At a meeting of the Cerne Board of Guardians on the 8th inst., it was unanimously resolved that the authorities having control over the superannuation allowance of the relieving medical superintendent of this asylum be memorialised to recommend that only a minimum pension be granted. The Visiting Committee of the institution have recommended that the allowance should be £600 per annum.

HOSPITALS ASSOCIATION. On the 15th inst. Sir William Mac Cormac presided at a meeting of this Association, when a paper on "Foundling Hospitals at Home and Abroad" was read by Mr. Samuel Osborn, F.R.C.S., who confined his observations on foreign hospitals almost entirely to those of St. Petersburg and Moscow, which he visited this year, and concluded by giving a detailed account of the institution in Guildford-street. A short discussion followed the reading of the paper.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARKENDT, FRANK H., M.R.C.S., L.R.C.P.Lond., has been appointed Senior House-Surgeon to the Bootle Borough Hospital.

BLUMER, G. ALDER, M.D., L.R.C.P., L.R.C.S.Ed., has been appointed Medical Superintendent to the State Lunatic Asylum, Utica, New York, U.S.A., vice John P. Gray, M.D., LL.D., deceased.

COCKING, W. T., M.B.Lond., has been appointed Obstetric Assistant to University College Hospital.

HOUGHTON, F. E. CAULFEILD, M.R.C.S., L.R.C.P.Ed., has been appointed Surgeon to the Royal Small Arms Factory, Birmingham, vice Popham, resigned.

HUGHES, S., M.B., C.M.Edin., M.R.C.S., L.S.A., late House-Surgeon to the Royal Infirmary, Liverpool, has been appointed Senior House-Surgeon to the Borough Hospital, Birkenhead, vice Richardson, resigned.

KERR, DANIEL O., M.B., C.M.Ed., has been appointed Medical Officer for the Keelby District of the Caistor Union.

KEYWORTH, ARTHUR F., L.K.Q.C.P.I., L.M., has been appointed Medical Officer to the Manchester, Sheffield, and Lincolnshire Railway Mutual Provident Society for the Marple and Hayfield District, vice John Howe, M.R.C.S., L.S.A., deceased.

KINSEY-MORGAN, A., M.R.C.S., L.S.A., has been appointed Medical Officer of Health for Bournemouth.

MANTON, J. D., M.R.C.S., L.R.C.P.Lond., has been appointed Assistant Medical Officer to the Nottingham Friendly Societies' Medical Institution.

MARRIOTT, HYDE, B.Sc.Lond., M.R.C.S., has been appointed Obstetric Assistant to University College Hospital.

MUGGOOD, SIDNEY A., M.R.C.S., L.R.C.P.Lond., has been appointed Resident Medical Officer to the Kensington Dispensary, vice Buck, resigned.

ROGERS, J. H., L.R.C.P., L.R.C.S., has been appointed Resident Medical Officer to the Nottingham Friendly Societies' Medical Institution.

WARD, J. O., M.R.C.S., L.S.A., has been appointed Medical Officer to the Fourth District of the Pontefract Union.

WILKINSON, GEORGE T., L.R.C.S.I., L.R.C.P.Ed., has been appointed Assistant Rural Medical Officer for the Scalby District of the Scarborough Union.

Births, Marriages, and Deaths.

BIRTHS.

CHAMBERS.—On the 7th inst., at Amwell-street, E.C., the wife of E. Chambers, M.B., of a daughter.

COCKERILL.—On the 8th inst., at Netley Abbey, Southampton, the wife of John W. Cockerill, Army Medical Staff, of a daughter.

GILBERTSON.—On the 9th inst., at The Limes, Hitchin, the wife of James Henry Gilbertson, L.R.C.P.Lond., M.R.C.S., of a son.

INMAN.—On the 14th inst., at Hackney road, E., the wife of R. E. Inman, M.R.C.S., of a daughter.

OPIE.—On the 8th inst., at Hartington-villas, Beckenham, Kent, the wife of Edward A. Opie, M.B., of a son.

MARRIAGES.

ANDERSON—MOON.—On the 8th inst., at Edenfield, Cupar, Fifeshire, Alexander M. Anderson, M.D., of Dundee, to Margaret Robertson, eldest daughter of the late William Moon, J.P., and of Mrs. Moon, of Edenfield.

KNOWLES—LONG.—On the 30th ult., at St. James's, Southbroom, Devizes, John Knowles, M.R.C.S., of Maidstone, to Annie Ada, daughter of William Long, of Devizes.

WALKER—MOXON.—On the 14th inst., at St. Giles', Northampton, by the Rev. John Brooke, Vicar of St. Katharine's, assisted by the Rev. R. A. White, Vicar of St. Giles', Norman Hendrie Walker, M.B., of Stalham, Norfolk, to Florence Katharine, eldest daughter of William Moxon, M.R.C.S., of Derngate, Northampton.

DEATHS.

BURY.—On the 9th inst., at his residence, Whetstone, N., George Bury, F.R.C.S.Eng., aged 77.

CATTLIN.—On the 13th ult., at Glendale, Surrey-road, Bournemouth, William Alfred Newman Cattlin, F.R.C.S.E. (Friends will kindly accept this intimation.)

DAVIES.—On the 8th inst., at Borrowcop, Lichfield, Robert Alexander Davies, M.D., formerly Medical Superintendent of Burntwood Asylum, co. Stafford.

FERGUS.—On the 8th inst., at Ryton-on-Tyne, Walter Fergus, M.D., M.R.C.S., late Medical Officer at Marlborough College.

GREAVES.—On the 10th inst., at Burton-on-Trent, George Greaves, L.S.A., in his 82nd year.

WATSON.—On the 13th inst., at Woodside-terrace, Glasgow, Ebenezer Watson, M.D.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE ABERDEEN CHAIR OF MATERIA MEDICA.

A CORRESPONDENT—graduate of Aberdeen—is somewhat surprised at receiving a circular from a number of gentlemen asking for the expression of approval of Dr. Bridger's candidature for the chair of Materia Medica in Aberdeen University. The appointment is in the gift of the Crown, and our correspondent evidently thinks it a somewhat bold thing to think of influencing the Crown. But in actual practice the Crown is not so inaccessible nor so independent of information as he seems to think. In the contest for Crown chairs, though we see no objection to any fair pressure of any man's claims, we should deprecate general and promiscuous appeals to the profession.

Mr. Waye (Millom).—There are so many good books on hygiene that selection is difficult and advice invidious. The well-known works of Parkes, Wynter Blyth, Cornelius Fox, Wanklyn, Frankland, Bell, and Hassall would all be useful to our correspondent, and others might be mentioned.

J. R. I. R.—Our correspondent would do well to forward the advertisement to the Royal College of Surgeons, from whom the diploma has been obtained, in virtue of which registration is claimed. There is nothing in the announcement absolutely to show that the surgeon was the author of it.

Mr. F. W. Gibbon, L.R.C.P.Ed., L.S.A.Lond., &c.—We have no knowledge of any proposed establishment of pupilage in the medical curriculum.

Dr. Popow.—We cannot exchange.

FRIENDLY SOCIETIES AND THEIR MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—If you will kindly insert the following lines some of your readers may be able to tell me the rights of this question.

I have been surgeon to a Court of Foresters for more than ten years. A man, who was a member before I became the surgeon, has during the whole of my tenure of the appointment lived out of the district and paid his doctor's contribution to the surgeon of a court elsewhere. Having been ill for some months he now returns to his native place and expects to have my attendance, though he has never paid the usual contribution to me. He would of course during residence in the district pay like the others to the proper court surgeon (myself), but I, in a wholly amicable way, object to be responsible for him, as he is likely to be on the books for some time. Am I responsible?

I am, Sir, yours faithfully,

Dec. 14th, 1886. E.

MEDICINAL PRODUCTS OF AFGHANISTAN.

A PAPER was read on the 8th inst. before the Pharmaceutical Society of Great Britain by Dr. Aitchison, C.I.E., F.R.S., late naturalist with the Afghan Delimitation Commission, upon "Some Plants of Afghanistan, and their Medicinal Products." It appears that in Afghanistan umbelliferous plants form the characteristic type of the vegetation, the country in which they flourish consisting of great shingle and conglomerate plains lying between hills and river beds. Only about 1 out of 100 plants bear a flowering stem, and a native will assert that such a flower-bearing plant has nothing to do with the plants that yield asafœtida. The Dorema ammoniacum grows along with the asafœtida plant, and is equally abundant. Dr. Aitchison also describes as a new species (Ferula suaveolens, Aitch. and Helmsley) a plant the scented root of which, under the name of "sambal," is exported through Persia to the coast. Several kinds of manna are also produced, which are largely eaten by the people as a sweetmeat and exported in quantity to Persia and India. Among other plants and plant products met with by Dr. Aitchison were a very handsome species of Rheum, the ripe fruit of which is used by the natives as a purgative, and Orchis latifolia (Linn.), the dried tubes of which are known as "salep."

Dr. R. Neale.—The transliteration of Russian words and names into Roman characters is carried out under numerous systems, and often puzzles highly educated Russians themselves. The system adopted in THE LANCET, when referring to an author who writes in Russian, is much the same as that employed in the catalogue of the British Museum. When, however, reference is made to quotations from Russian authors in French or German publications the orthography employed in the latter is usually retained. Thus, taking the name mentioned by our correspondent, Cheltsoff or Tschelzoff, the Russian letter *che*, which has the sound of the *ch* in *change*, has to be written *tsch* in German, and *tch* in French, as *ch* in those languages would convey erroneous impressions of the sound. Again, the *tse* is equivalent to the German *z*, but not to the English or French *z*. It is the initial letter of the well-known word "Czar," or "Tsar." All this, as well as a great deal more, which would require a long essay to discuss, makes the compilation of an index containing Russian names a very difficult matter, which may be illustrated by the annoyances caused by the numerous ways of spelling and cataloguing the names of Indian towns.

M.R.C.S., L.R.C.P.—Our correspondent may with advantage refer to THE LANCET of April 18th, 1885, p. 735.

CASEINE IN HUMAN MILK.

To the Editor of THE LANCET.

SIR,—In view of the recent discussion upon infant feeding which has been carried on in your columns, may I be allowed to draw attention to the question, How much caseine is contained in human milk? Now, without mentioning earlier writings, I find that Dr. Eustace Smith, Dr. Goodhart, and Dr. Galabin, all of whose text-books are very modern, agree in accepting (or, at any rate, in offering for their readers' acceptance) analyses which represent human milk as containing from 3 to 4 per cent. of caseine. On turning, however, to the chapter on Food in Drs. Meigs and Pepper's work on the Diseases of Children I find that these authors reject as untrustworthy all such analyses, and accept as substantially correct an analysis which gives 1·5 per cent. of caseine. In support of this preference they quote Dr. A. Meigs, who declares that no specimen of human milk which he had examined contained so much as 2 per cent. of caseine. Other analyses giving very similar results are quoted by Dr. Ashby in an article in the *Medical Chronicle* for May in the present year. The question whether the older analyses, which are still current even in the most recently issued text-books, or the newer analyses to which I have here alluded, are correct is one of great practical importance. For, however fully we may believe that clinical experience counts for more than chemistry, we cannot afford to neglect any aid which may be derived from analysis when we set ourselves to produce with the use of cow's milk an imitation of an infant's natural diet. For example, when the question of the appropriate degree of dilution for cow's milk is under consideration, are we to take it as true that human milk contains more than 3 or less than 2 per cent. of caseine? If the more recent analyses are to be received, is it not time that they should be finding their way into English text-books?

I am, Sir, yours truly,

Dec. 7th, 1886. R. J. R.

RELIGIOUS RESTRICTIONS ON A NEW MEDICAL SCHOLARSHIP.

A SUBSCRIPTION amounting to £400 has been raised by the colleagues and admirers of Prof. Karavayeff, the eminent Kieff surgeon, for the purpose of founding a scholarship in his honour for students in the medical faculty. It appears, however, that candidates must be of the "orthodox" faith; so that Lutherans, Dissenters, and Jews are debarred the chance of obtaining either the honour or emolument attaching to the possession of a Karavayeff scholarship.

Mr. W. Curran.—Yes.

ROYAL UNIVERSITY WORK IN IRELAND.

Audi alteram partem is thanked for his letter, though it is too long for insertion. He vindicates the work of the Royal University. He admits it is not perfect, owing to lack of properly equipped laboratories and some defects of method, but thinks it is, on the whole, worthy of encouragement. He praises especially the Arts Examination, which, he says, is as good as Cambridge, requiring a good honest year's work, and alleges that the medical curriculum is improved in many respects—viz., the enforcement of adequate study of lunacy, fever, gynæcology, and ophthalmology, following in this respect the example of all progressive institutions here and on the Continent.

Mr. H. H. Sturge.—There is no publisher's name on the title-page. Our correspondent had better write to the author of the pamphlet.

HOSPITAL APPOINTMENTS.

To the Editor of THE LANCET.

SIR,—I am pleased to find that in your issue of Dec. 11th your powerful voice has been raised in protest against the monopoly at present existing in hospital appointments. Your remarks upon hospital appointments and degrees in surgery apply with even greater force to medical degrees and appointments; though I am afraid that in neither case is your suggested remedy of "addressing the bodies whose licentiates and graduates are injured" practicable, or at all likely to lead to any good result. The Fellows and Members of these same bodies are themselves either directly or indirectly interested in maintaining the *status quo*. The value of their diplomas is distinctly enhanced by the privileges they carry of rendering their happy possessors alone capable of applying for hospital appointments, and as they form the governing power of the bodies in question it can hardly be expected that they will be very active in the matter. To a certain extent members of the College of Surgeons are in a much better position in this respect than the licentiates of the College of Physicians. In the former case any Member on passing the required examination is admitted to the Fellowship without let or hindrance; in the latter, not only must an examination be passed, but such restrictions are placed upon the would-be members as practically to render the diploma untenable except by those whose means are to a greater or less extent independent of the practice of their profession. I need hardly point out in detail how injuriously such a system acts, not only upon the profession itself, but also upon the public at large, closing as it does the door of professional advancement upon a body of highly-trained and experienced members of the profession, who from want of means or some similar cause, not from want of ability, are effectually precluded from competing with their more favoured brethren.

I am, Sir, yours obediently,

Dec. 13th, 1886. REFORM.

SIR WM. MACCORMAC'S CASES OF RUPTURED BLADDER.

In the account of the cases of ruptured bladder under the care of Sir William Mac Cormac which was published in our last issue, on page 1118, paragraph 2, line 4, the date should be 1884, not, as printed, 1885. The two cases were admitted during Sir William's two consecutive "taking in" weeks, rare cases not infrequently occurring in pairs. The second patient, we may add, is perfectly well and shortly about to resume his occupation. Each man was provided with a fitted abdominal support to prevent any yielding along the line of cicatrix and the formation of ventral hernia.

Mr. C. S. Jeaffreson (Newcastle-on-Tyne).—Yes, if not too long.

TRIPLETS.

To the Editor of THE LANCET.

SIR,—The following case seems of some interest.

Mrs. C——, wife of the gardener of this hospital, was delivered of triplets on Sept. 10th last. The children were all males. There were three amniotic sacs and three placentæ, two of which were slightly attached. The first child and also the last presented by the shoulder; the second was a face presentation. The children were small and feeble. One died twenty-four hours after birth; another lived three days; the third lived seven days.—I am, Sir, yours faithfully,

M. JOHNSTON, House-Surgeon.

County Hospital, Lincoln, Nov. 17th, 1886.

RECTAL MEDICATION.

Dr. C. F. Knight (Dublin) calls our attention to the fact that he sent to us in 1878 a communication regarding "Medication per Rectum," in 1880 a second, and in 1883 a third communication on the same subject, but under the above heading. In these articles he advocated the administration of certain therapeutic agents in the form of vapours in particular diseases, as cholera, fevers, phthisis, &c. In 1883 he devised an instrument for such medication, and the method is, he understands, now followed at many of the continental hospitals, and has still more recently been introduced into one or two London hospitals. (See THE LANCET, Aug. 7th, 1886.)

X. Y. Z.—We cannot reply with certainty, but should advise our correspondent to ask the authority in charge of the failure for a direction for payment in full.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE following were the questions on Anatomy submitted to the candidates at the first examination for the diploma of Fellow of the College on the 10th ult., when they were required to answer at least three of the four questions between 11 A.M. and 2 P.M.:—

1. Describe the soft palate; and (*a*) mention in their order, from above downwards, the several structures met with in its dissection; (*b*) state the sources of its arterial and sensory nerve-supply; (*c*) give the extrinsic attachments and the motor-nerve of each muscle.

2. Give the origin, course, and distribution of the branches of artery supplying the various parts of the brain and its membranes.

3. Describe the position and shape of the first rib. Give its relations and the muscular and ligamentous attachments to it. How is it developed?

4. Describe fully the levator ani muscle, giving its relations and nerve-supply.

The following were the questions on Physiology, of which it was necessary to answer three of the four between 3 and 6 P.M.:—

1. Name the proteids which occur in the human organism. State their general properties, and the special characteristics by which the different varieties may be distinguished.

2. Explain the effect upon the blood, blood-pressure, and excretions of diminishing the volume of the blood by bleeding, and of increasing it by the transfusion of normal living and of whipped blood.

3. What is meant by the cortical motor-centres, and in what region of the brain are they situated? What do you know by experiment or otherwise of their use?

4. Describe the mode of origin and state the destination of the Wolffian and Müllerian ducts.

The following were the questions on Pathology, Therapeutics, and Surgery submitted to the candidates at the second examination for the diploma of Fellow on the 24th ult., when all four questions had to be answered between 1.30 and 5.30 P.M.:—

1. Describe, and contrast clinically and pathologically, the conditions known as (*a*) pulpy degeneration of synovial membrane, (*b*) Charcot's joint-disease, (*c*) chronic rheumatoid arthritis.

2. Give the symptoms, diagnosis, and treatment of tetanus, and discuss the causes and pathology of the disease.

3. Give the pathology, symptoms, and treatment, general and operative, of malignant disease of the rectum.

4. Describe the various forms of gangrene of the lower extremity, and state fully the treatment appropriate to each.

Mr. T. Laffan.—We have no knowledge of any prize for an essay on Diphtheria save that given by the Empress of Germany some three or four years ago.

Messrs. J. & A. Churchill.—Dr. D. Pi y Molist's work on "Don Quixote from a Medical Point of View" could probably be obtained from "La Reducion de la Independencia Médica, Carmen 31, Barcelona."

PERSISTENT DIARRHŒA.

To the Editor of THE LANCET.

SIR,—May I be permitted to ask for advice through your columns in the treatment of the following case.

I was consulted a few weeks ago by a young lady who looked the picture of health, but who complained that for the last two years she had continually suffered from diarrhœa, accompanied by considerable griping pain in the abdomen. The causes which seem to have produced the diarrhœa were any deviation from the most simple diet and excitement. For two years she had scarcely tasted vegetables, and whenever she had done so she suffered from pain and diarrhœa. She stated that potato, even in small quantities, produced as unpleasant effects as anything. When going to a dance or dinner party she invariably suffered pain, and frequently had to return home on account of diarrhœa coming on. She had been under treatment by another practitioner for some time, and had always kept a mixture containing chlorodyne in the house, a dose of which she had taken whenever she was going out to any entertainment likely to cause the diarrhœa. I commenced treating her with ten grains of bromide of potassium and five minims of tincture of belladonna three times a day, and after a few days increased the dose of bromide to twenty grains. The only apparent effect of this was that she complained of feeling very low-spirited. After about ten days of this treatment I discontinued the bromide and belladonna, and ordered her mineral acids and nux vomica. I also advised her to commence trying to eat very small quantities of well-cooked floury potato with her food, and to have a cold sponge-bath every morning. She now feels very well, except that she has pain and looseness of the bowels after the potato, as before. There is thoroughly good reaction after the cold bath. Her friends tell me that she has never shown any symptoms of hysteria, nor does she appear to be hysterical. Her manner is always quiet and self-possessed. She is naturally very anxious to get rid of the constant discomfort and annoyance, and I am unwilling that she should continue the practice of taking opiates and avoiding vegetables. I shall be very thankful for any suggestions in the treatment of this case.

I am, Sir, yours truly,

Dec. 14th, 1886. A. H.

LIFE ASSURANCE.

WE quite agree with the opinion expressed in a leader of the last issue of the *Policyholder*, that parents could not spend money to greater advantage upon their sons than by insuring their lives when they had reached about fifteen years of age. Such policies would be sure to be kept up, and would prove of great value either as a family provision or to meet business requirements.

Mr. Browning.—The matter is discussed in our current number.

ABSTRACT OF THE

Brown Lectures.

Delivered at the University of London,

BY VICTOR HORSLEY, F.R.C.S., F.R.S.

EPILEPSY.

LECTURE III.

MR. VICTOR HORSLEY said that he intended to give in detail an account of recent experimental research into the nature and pathology of epilepsy. The first of the three lectures was devoted to classification, and he proposed only to deal with epilepsy so far as it could be studied experimentally, though the results of experimental science had been somewhat ridiculed by clinical physicians. Experimental results were, however, infinitely more exact than those of clinical observation. A passage from Dr. Gowers' work on Epilepsy and other Chronic Convulsive Disorders, quoting Dr. Russell Reynolds, was read to show that the experimental work had been dragged into a false position. The lecturer next asked the question, "What do we mean by epilepsy?" and proceeded to give the classifications in vogue. Dr. Hughlings Jackson distinguished epilepsia gravior, epilepsy from discharges in the bulb and pons, and epileptiform seizures (Jacksonian Epilepsy). Dr. Russell Reynolds divided epilepsia gravior into those cases with loss and those without loss of consciousness, and also divided epilepsia mitior into those with and those without spasm. Dr. Gowers and Dr. Ross described as functional epilepsia gravior and mitior, and as organic epileptiform seizures. It was customary to consider hystero-epilepsy, epileptiform seizures, laryngismus stridulus, and eclampsia as altogether apart from epilepsy. Mr. Horsley thought that the omission to consider these diseases or conditions under epilepsy was unwarrantable. Experimental research showed that epilepsy could originate from discharges in the motor cortex of the brain and from discharges in the bulbo-spinal centres. For the present the hypothesis of Nothnagel, that there existed a special convulsive centre in the bulb and pons, as well as the views of others as to the convulsive centre of the bulb alone, must be set aside. Ferrier believes that movements may be evoked by stimulation of the corpus striatum, but Mr. Horsley had been unable to corroborate this. Nothnagel, in Ziemssen's Cyclopædia, in one and the same sentence, allows that the same mechanism in the brain may produce both epileptiform seizures and epileptic convulsions. This confusion of terminology must always remain until an exact division of symptoms is arrived at, and this coupled with an exact anatomical knowledge of the locality where the discharge begins and its mode of spread. The two essentials of epilepsy, according to Dr. Russell Reynolds, were diminution of intelligence and muscular spasm. An anatomical classification of epilepsy demands that we should know the locality of origin of disturbance, the locality of source of spasm, and the locality of the whole disturbance, which may or may not be the whole of the central nervous system. The disturbance might begin in any part of the encephalon, and, if in the perceptive centres, would readily explain the diminution of intelligence. The next possible anatomical basis of classification was in determining the locality of the source of spasm. Experimental stimulation of the motor cerebral cortex gave rise to definite movements, for this region the representation of movement was, so far as known, the most localised. Epilepsy induced from the cortex of the brain was characterised by tonic spasm followed by clonic spasm, as in epilepsia gravior. Epilepsy excited from bulbo-spinal centres was generally simply clonic, but might be clonic; the sequence of clonic on tonic was wanting. Tetanus and ankle clonus were of bulbo-spinal source, and possibly laryngismus also. Hystero-epilepsy was probably a cortical disease, as epileptiform seizures dependent on organic lesions undoubtedly were. Probably eclampsia, epilepsia mitior, and laryngismus stridulus were of cortical origin. Mr. Horsley and Dr. Semon had discovered cortical centres for the adductor action of the vocal cords. It must remain doubtful whether tumours of the pons cause epilepsy by discharging a local mechanism (Nothnagel). The spasms in hystero-epilepsy at the onset of the attack were of the tonic followed by the clonic character, as graphic records showed. This fact, together with the remarkable coördinated movements in the later stage, were sufficient to prove hystero-epilepsy to be, at least primarily, a cortical affection.

LECTURE IV.

The second lecture on epilepsy was devoted to the question of the existence of special convulsive centres either in the pons Varolii or medulla oblongata. Mr. Horsley gave a detailed account of the various investigations, and showed that neither taken singly nor collectively could the results of these experiments be accepted as proving the existence of special convulsive centres. Such a hypothesis as that of Nothnagel and others was entirely unnecessary, for all the ascertained facts could be perfectly and harmoniously interpreted without it. Mr. Horsley believes that all the convulsive, tonic and clonic, phenomena may originate from the ordinary bulbo-spinal centres such as exist for carrying out normal mechanisms. Tonic or clonic spasm, then, may be produced by any motor nerve centre, but the combination and sequence of tonic-clonic could originate only from the cerebral motor cortex. It was an interesting and important but unsolved problem whether the clonic spasm of cortical epilepsy was the effect of cortical or bulbo-spinal discharges. Conceivably the cortical centre may discharge the energy pent up in the bulbo-spinal centre, but the violent rush of energy from the cortex might be simply passed along by the bulbo-spinal centre, which thus would act as a mere conductor. The tonic spasm resulting from cortical stimulation was a tetanus compounded of a series of muscular contractions, which, though fused in the tetanus, could yet be seen as waves on the continued curve, which had a definite rate of twelve to thirteen per second. The rate of discharge from the spinal motor centres is about eight to ten per second.[1] What was really wanted was a knowledge of the rate of nerve impulses passing along the pyramidal tracts. This might be ascertained by the use of Lippmann's electrometer and observing the variations of the electric potential. This was a point for future investigation. It has been proved experimentally that the only seats of motor nerve discharge in monkeys and dogs were the cortical and bulbo-spinal. Attention must next be turned to rodents, and in these animals, with but very imperfectly evolved nervous systems, the representation of movements in the cortex of the brain appeared to be of a very imperfect kind. In rodents the most careful work had been done by Franck and Pitres. They could not obtain the sequence of tonic-clonic from exciting the cortex of the brain of rabbits and guinea-pigs. Mr. Horsley had confirmed their observations; the spasm resulting from electrical excitation was sometimes tonic and sometimes clonic i.e., of a mixed type. But the subject requires further investigation. The differences between these lower and the other higher mammalia might be explained as the result of imperfect evolution of centres, and, above all, imperfect differentiation between the cortical and bulbo-spinal systems. The problem was as follows: Given a convulsion in the rabbit or guinea-pig composed of tonic and clonic spasms, what is the locality of the motor disturbance?

Nothnagel's experiments were made by 1. Injections of chromic acid into the substance of the brain. These were so inexact as to need no further discussion. 2. Puncture with a needle. Punctures were made—(*a*) about the posterior end of the only sulcus that exists in the hemisphere of the rabbit; (*b*) about the bulb, in a region between the acoustic nucleus on the outside, the eminentia teres on the inside, and the calamus behind. In most cases the needle was driven through the floor of the ventricle nearly to the bone. Mr. Horsley showed that both of these punctures necessarily damaged the motor tracts going from the cortex down to the cord. When the puncture was made in the hemisphere, there was opisthotonos, contraction of pupil, tonic spasm alternating with violent clonic spasm, and ending in tetanus; the jaw and face showed tonic spasm. When the puncture was made through the floor of the fourth ventricle, the face and jaw

[1] THE LANCET, vol. ii., 1886, p. 359.

were not affected, and the pupil was dilated, but the other phenomena remained the same. After the convulsions had been induced by this puncture it was found that the attacks recurred spontaneously. Now, in these experiments a lesion of the motor tracts was produced, and there was no definite series of muscular movements. The work of Kussmaul and Tenner, of Brown-Séquard, of Prevost of Geneva, Landois, Hermann, and Escher, constituted a series of experimental production of convulsions by vascular disturbance. Kussmaul and Tenner caused anæmia of the brain by ligature of both arteries going to the brain or by bleeding. The series of phenomena they observed were given in detail, and it was noted that considerable confusion existed as to the sequence and combination of tonic and clonic spasm. By compressing the aorta of rabbits, as had been done by Brown-Séquard and Prevost, muscular twitching and clonic spasms in the legs were evoked. These could not be explained as the result of anæmia of the legs, for ligature of the arteries going to them caused no such clonic movements. There was no doubt that they were due to anæmia of the lower end of the spinal cord, which received its chief blood-supply from the abdominal aorta by branches through the intervertebral foramina.

The next series of observations were those in which the convulsions were elicited by reflex irritation. Brown-Séquard had two methods of doing this—(1) hemisection of the cord, and especially of the posterior columns; (2) production of injury to the sciatic nerve. Westphal rendered guinea-pigs "epileptic" also by percussion of the frontal region, which doubtless caused minute hæmorrhages in the fourth ventricle as the effect of a kind of *contrecoup*. It was important to know, as Mr. Horsley had definitely determined, that there was no need in Brown-Séquard's methods that the wounds should suppurate, or even inflame much; even if primary union were obtained by antiseptic methods, the nervous effects followed equally well. In this so-called "epilepsy" of guinea-pigs it was most important to observe that the convulsive movements did not commence immediately after the operation. In France there was an "incubation period" of two weeks; in England and the United States a longer period of six weeks. Was it too much to suppose that there were racial differences even in animals, bearing in mind the greater frequency of hystero-epilepsy with the French? A fully developed fit was not the first thing to be observed; there was always a gradual development. The fits were evoked by touching the epileptogenous zone, which in the guinea-pig was on the same side of the head as the hemisection of the cord, or injury to the sciatic nerve. At first nothing more than a slight tonic spasm, causing the head to deviate to the same side as the lesion, would be observed. Later a complete fit would occur, and the phenomena were, in order, (1) slight period of latency after stroking the region of the angle of the jaw and behind the ear; (2) lateral tonic spasm as above, followed by complete pleurosthotonos, and spreading movements of the toes from tonic spasm in the limbs; (3) loss of consciousness, as inferred by the insensitivity of the conjunctiva, and the animal's falling over on its back. (4) then rapid clonic spasm of the whole four limbs, with genuine opisthotonos and opening of the mouth, so that the head and trunk was in a tonic and the belly and limbs in a clonic state. There seemed to be little doubt that the induced epilepsy was a pure neurosis. The incubation period and the slow development of the disease were very important features. The matter was still under investigation. Mr. Horsley considered that there was nothing in the results of the experimental researches that necessitated the hypothesis of a special coördinating convulsive centre. Coördination was effected by the functional and structural union of all bulbo-spinal centres. The so-called respiratory centres, probably brought into play the lower centres, innervating the respiratory muscles. In Landois', Hermann's, and Escher's experiments of ligaturing the veins returning blood from the head, the venous stagnation and plethora thus produced were followed by coma and convulsions; the fact was interesting, but too much stress could not be laid on it as proving any theory, vaso-motor or other, of epilepsy.

LECTURE V.

This lecture was occupied with the discussion of the convulsions evoked by discharge from the motor part of the cortex cerebri. It was possible that the part of the cortex producing the convulsion might be sensory (Ferrier) as well as motor. Ferrier had evoked convulsions by stimulating the temporo-sphenoidal lobe. The convulsion in which tonic spasm followed by clonic spasm was the essential feature was clearly shown by experiment to be dependent on the cortex cerebri. Stimulation of the fibres of the corona radiata, after cutting away the cortex, did not produce the typical series of events—tonic, clonic. Mr. Horsley had observed that there was a great difference between different monkeys and different parts of the motor cortex in respect of the facility with which convulsions could be evoked. The conditions of the cerebrum under which epileptogenous states are excitable were very numerous. Individual peculiarity was an important factor; so also were age, illness, and drugs, like absinthe and alcohol. If a monkey were lowered in health as the result of diarrhœa, a convulsion was more easily elicited than in the same animal when well. Old people and animals were less liable to cortical epilepsy, and, generally, very young animals also. Absinthe and alcohol injected into the venous circulation might spontaneously originate convulsions of cortical type. Coarse disease, such as septic meningitis, traumatisms, and new growths, could also excite true cortical convulsions, and of course electricity, employed experimentally. The general characteristics of the convulsion were the presence of a period of latency, then tonic spasm, then clonic spasm, arrest of respiration, with cyanosis and salivation, though the precise relationship of these phenomena to one another could not be proved as yet. There was also an effect on the heart. Paralysis and mania followed not only in man but in the lower animals.

Dr. Hughlings Jackson's views of the representation of movements in the hemispheres were sketched, and the chief point in them, so far as the present subject went, was that each hemisphere represented both sides of the body. The representation of the opposite side was most marked, but still there was a degree of representation of the same side of the body in the same cerebral hemisphere. According to these theoretical views of Dr. Hughlings Jackson, it would be possible to evoke convulsions of the whole of the body by stimulating one motor centre. The upper arm centre, for example, if stimulated, would produce movements in the opposite shoulder, but theoretically it could cause spasm down the opposite arm, down the opposite leg, the trunk, head, neck, and face, and then invade the muscles of the same side of the body as the stimulated centre, and in the same order above mentioned. In such a fashion is this representation imagined that the left lower part of the face would be represented, but the least so in the left upper arm centre. However probable these views might be theoretically, Mr. Horsley said that they obtained no proof, either clinically or experimentally. Clinical and experimental evidence simply showed that one half of the body was represented in the opposite hemisphere, with but few exceptions. Experiments, moreover, did not support Broadbent's hypothesis.[2] It was important to determine whether a passage of nervous energy or discharge could take place across from one hemisphere to another by way of the corpus callosum. Mr. Horsley quoted an observation made on a boy who was the victim of tubercular meningitis. The right arm was paralysed and rigid; on flexing it forcibly, it was found that the left arm became adducted. There was no doubt of the causal relationship between the two phenomena. The interval that elapsed between the cause in the right arm and the contraction in the left was always a second, and sometimes longer. This time was far longer than would be necessary for the passage of energy from one anterior spinal horn to the other. Mr. Horsley suggested that the nerve impulse from forcible flexion of the rigid arm passed upwards to the left hemisphere, and then discharged the energy in the right hemisphere by way of the corpus callosum. At the necropsy a conglomeration of tubercles was found in the left motor cortex, which explained the palsy and rigidity. The diagnosis of the lesion was made during life. Tracings of the convulsions in cortical epilepsy proved also that there must be a passage of nervous energy though the corpus callosum. It has been shown that the sequences of tonic-clonic spasm can only occur when the cortex is discharging. If the convulsion be bilateral when the cause is unilateral, and if the bilateral convulsion have the cortical character, it is clear in the light of experimental evidence

[2] See article on Substitutions in THE LANCET, vol. ii. 1884, p. 7.

that the two hemispheres must have been discharging. The march of the spasm in cortical epilepsy is explained on the facts of experimentation as discovered by Ferrier, Schäfer, and Horsley. If the spasm begins in the right face, it passes to the arm, then to the leg, and then to the trunk of the same side; the convulsions, as a rule, begin later in the left limbs. The experimental evidence on this matter was detailed. Albertoni operated on dogs and ablated one motor area, and some days later exposed the opposite hemisphere, and on excitation he obtained generalised bilateral fits. This would seem to be contrary to the above views, but Mr. Horsley said that it was doubtful whether all the motor areas on one side had been removed. Franck and Pitres had operated on one cat by dividing the corpus callosum, and found that a cortical convulsion (i. e., tonic followed by clonic) could be obtained in all four limbs. It may be that these adverse facts can be explained on the knowledge that in the carnivora and some human beings the course taken by the fibres of the pyramidal tracts would seem to be bilateral in the cord for each hemisphere. So that anatomically there is some ground for expecting some bilateral effect when one hemisphere discharged. What, however, is the clinical and experimental fact? Mr. Horsley next gave in detail certain experimental and clinical evidence which seemed to show conclusively that, as a rule, each hemisphere convulsed its own (the opposite) side of the body. In hemiplegia, if the motor cortex was completely cut off the limbs remained permanently paralysed. Then, again, in unilateral fits there was no necessary spread to the opposite side of the body. In one monkey with unilateral cortical fits induced by electricity the muscles of the back and belly were convulsed only on the one side, showing that even such muscles as are supposed to act bilaterally and to be closely united spinally, did not do so in cortical fits—a strong argument against Broadbent's explanation of the escape of certain groups of muscles in ordinary hemiplegia. A case of Obeke's was also narrated as bearing on the point.[3] It was a case of con-

[3] Berlin. Klin. Wochen., 1880, p. 534, No. 37.

genital epilepsy and mental enfeeblement; the epilepsy was bilateral. Late in life a hæmorrhage occurred into the right internal capsule, destroying it and producing complete left hemiplegia and hemianæsthesia. After this attack, whenever the epilepsy appeared, it did not affect the left side of the body. The conclusion to be arrived at was that the bilateral representation, if it exists, is very imperfect.

Mr. Horsley next gave an account of experiments made by him which seemed to prove the same conclusion. In the first group of experiments the corpus callosum was completely divided. In the first dog the division was found to be complete, and a slight injury had been done to the right internal capsule. Stimulation of either cortex caused tonic spasm only, no "cortical" epilepsy, in the opposite side of the body. In the second dog there was, besides division of the corpus callosum, slight injury to its anterior end; in this case there was epilepsy, but only in the side of the body opposite to the hemisphere stimulated. In the third dog the division of the corpus callosum was perfect, save at the lower border of the rostrum. Stimulation of one cortex produced tonic spasm in the proximal segments of all four limbs, but genuine epilepsy only in the opposite limbs. In a monkey, the corpus callosum, anterior commissure, median commissure, and fornix were all completely divided, with the result that cortical stimulation caused epilepsy only in the opposite limbs. In the second group of experiments the motor centres were excised and the electrical stimulation practised on both hemispheres. In a monkey, the right motor centres were freely excised, with consequent left hemiplegia. Excitation of either hemisphere produced bilateral epilepsy, provided a very strong current were used. When the right hemisphere was alone stimulated by a moderate current, the convulsions were very marked, but only in the *right* limbs; there were practically no convulsions in the *left* limbs. It should be said that the whole of the right motor region was not entirely removed. When the left hemisphere was stimulated, the convulsions were very well marked in the right limbs, but absent from the left. Hitzig and Luciani had worked at the same subject. In the third class of experiments means were taken to depress the activity of the cortex of the brain on one side. A monkey was trephined on the right side and the wound allowed to become septic, with consequent meningitis; and at the end of two days the left limbs were found to be paralysed, but not completely. Excitation of the right hemisphere produced generalised epilepsy, but almost absolutely right-sided. In this case the passage of energy through the corpus callosum must have taken place, but the stimulated right cortex was unable to respond in the form of cortical epilepsy of the left limbs owing to its depressed state, it being the seat of septic meningitis with venous stagnation and consequent innutrition. In the fourth class of experiments an artificial tumour was produced in the subcortical region, and therefore damaging the fibres of the corona radiata. An injection was made of thin plaster-of-Paris by means of a syringe plunged through a part of the motor cortex. This was done in a monkey on the left side of the brain. Excitation of this left hemisphere caused no effect on the right limbs of the body, but evoked powerful epilepsy, which affected both eyelids and eyes, but only the left side of the face, trunk, and left limbs. Here it would seem that the artificial tumour in the left corona radiata had cut off the path leading from the left cortex to the right half of the body, but had not destroyed the fibres that passed from the left to the right motor cortex. The mere presence of the tumour did not appear to excite any epileptic effect. It would appear, therefore, that something other than mechanical pressure is necessary to put the nerve cells in that condition in which they discharge energy convulsively. The conclusions all round, therefore, were very emphatic, to the effect that convulsions due to cortical discharge are evoked in various groups of muscles by nerve energy proceeding from that centre in each hemisphere which is in relation to each group of muscles, and that in generalised epileptic convulsions both cerebral hemispheres are involved.

LITHOLAPAXY IN MALE CHILDREN AND MALE ADULTS.

BY SURGEON-MAJOR D. F. KEEGAN, M.D. DUB.,
RESIDENCY SURGEON, INDORE, CENTRAL INDIA.

(*Concluded from page 1170.*)

AT the close of the year 1883 a young man, aged twenty, was admitted into the Indore Hospital with stone in the bladder. The stone, which consisted of uric acid and weighed 1140 grains, was disposed of by litholapaxy, and he left the hospital perfectly well twenty days after the operation. Indeed, he might have returned to his home very much sooner, but it was considered wise to keep him for some days under observation in hospital. The notes of this case I have left behind me in India, and am not in a position at present to state how long the operation lasted, or the size of the lithotrite or evacuating catheters employed.

S. M——, aged sixty-seven, an inhabitant of Indore, was admitted into hospital on May 18th, 1884, suffering from symptoms of stone, which had existed for fifteen years. His face bore the traces of great suffering. The pain on passing urine was so great that sometimes he used to strike his forehead against the ground or against the wall of his room in paroxysms of despair. The urine was alkaline in reaction, and its specific gravity 1015. The same day I passed a No. 15 fenestrated lithotrite into the bladder and readily seized a very large stone. The bladder was healthy and roomy, and the urethra very capacious. The stone, however, I found too large to permit of its being cracked across with the lithotrite, and I had not a larger one in my possession. To have cut an old man with a large stone would almost certainly have killed him, and I therefore determined to chip away at the stone until I could so reduce it as to get the lithotrite to lock on it. I was obliged to spend a very long time in chipping away at the outer shell of the stone, and when nearly half an hour had elapsed I had the satisfaction of finding that I was able to lock the lithotrite. Once the stone was cracked across, the operation presented no remarkable features except its great tediousness. At the end of two hours I had only extracted half the stone, and I almost began to despair of success. But my old patient's pulse improved, his breathing was perfectly regular, and he required but little chloroform to keep him in a condition of perfect anæsthesia, and so I was determined to extract the entire stone at one sitting if possible. I was obliged to introduce the lithotrite fourteen [illegible] motor an equal number

of times. The evacuating catheter which I employed was a No. 29 (French scale). At the end of the fourth hour I had nearly extracted the entire stone, and the last quarter of an hour of the operation was spent in sounding and in disposing of the last few fragments. The stone consisted of urate of lime, and when damp weighed 1600 grs. I have weighed it recently, and after two hot weathers in India its weight is 1470 grs.—May 18th: Evening temperature 102·4°; pulse 96.—19th: Feels slight pain over bladder region: urine somewhat red; not much pain in micturition; has almost recovered from the effects of chloroform.—21st: Patient feels quite well; walks about his room; is anxious to go home.—23rd: A small lithotrite having been introduced into the bladder, a small fragment of stone was detected lying close to its neck, and was removed between the blades of the lithotrite.—24th: Urine perfectly clear: no pain in micturition. Allowed to return home.

The above case is a good example of the results which can be achieved by Bigelow's operation. Compare the history of this case after the operation of litholapaxy with what it would have been had I extracted the stone by supra-pubic cystotomy, and the superiority of Bigelow's method over other systems of treatment becomes very striking. This man was in the enjoyment of excellent health when I left India in March last, and was perfectly free from all bladder trouble. I may here mention that his testicles have never descended into the scrotum, or even into the inguinal canal. He affirms that he has had two children, and suffered once from syphilis and once from gonorrhœa, proving that a man may be the subject of retained abdominal testicles and still possess undiminished virile power.

M. S——, aged thirty years, admitted into the Indore Hospital on Feb. 1st, 1885, with symptoms of stone in the bladder. A No. 15 fenestrated lithotrite having been passed into the bladder, a large stone was easily seized and crushed. The lithotrite was introduced into the bladder eight times, and the débris evacuated through a No. 29 catheter (French scale). The operation lasted one hour and thirty-seven minutes, and the débris of the stone, which consisted of mixed uric acid and urate of ammonia, weighed 770 grs. The patient left the hospital quite well on the twelfth day succeeding the operation.

L——, aged thirty years, admitted into the Indore Hospital on May 20th, 1885, with stone symptoms, which had existed for twelve or fifteen years. A No. 15 fenestrated lithotrite being passed into the bladder, a stone was readily seized. The stone I found was a very hard one, and tested the strength of the lithotrite employed, one of Weiss and Son's make. The male blade seemed to me to sink into the stone. The lithotrite was introduced eleven different times, and the evacuating catheters employed were No. 16 English and No. 25 French scale. The operation lasted two hours and four minutes, and the stone extracted weighed 550 grains. It consisted of oxalate of lime, was quite black in colour, and was the hardest stone I have yet crushed. The man made an excellent recovery, and left the hospital quite well ten days after the operation. The lithotrite on this occasion did its work splendidly. The amount of pressure I was obliged to exert in screwing up the lithotrite was represented by the whole strength of my wrist and forearm. In attacking stones of this description, I screw up the lithotrite as tightly as I think I can do with safety, and then wait for some seconds before endeavouring to give the handle of the screw an extra half turn, and I generally find that in the interim the stone gives way with a snap under the continuous pressure exerted by the blades of the lithotrite. The screw power of the lithotrite should be worked judiciously and carefully when one meets with very hard stones. The inexperienced litholapaxist who, so to speak, "rushes" a hard mulberry calculus is not acting fairly either towards his patient or the surgical instrument maker. The blades of the best made lithotrite are liable to break if the whole power of the screw is rapidly brought into play against a very hard and tough stone.

M——, a man aged forty, was admitted into the Indore Hospital on July 3 d, 1885, suffering from stone symptoms, which had existed for some years. On introducing a No. 15 fenestrated lithotrite into the bladder, a large stone was readily seized and crushed. The stone was a very hard one. The lithotrite was introduced on six different occasions, and the débris extracted by a No. 16 evacuating catheter. The operation lasted eighty-eight minutes, and the stone, which consisted principally of large from the mixed of lithic acid. It was possible that the part of the cortex

some pain in passing urine.—5th: Pain much less; feels quite well. Sir Henry Thompson's sound being passed into the bladder, no particle of stone could be detected.—6th: Went home quite well.

M. S——, aged twenty-five years, admitted into the Indore Hospital on July 11th, 1885, with symptoms of stone, which had existed for some years. Next day, being placed under chloroform, a stone, consisting of lithic acid and oxalate of lime and weighing 787 grs., was evacuated from the bladder in seventy-five minutes. The lithotrites employed were Nos. 11 and 15, and the evacuating catheter used was a No. 16 (English scale). The patient made an excellent recovery, and left the hospital quite well on the seventh day succeeding the operation.

S. B——, aged thirty years, was admitted into the Indore Hospital on March 12th, 1886, suffering from stone in the bladder. This man's stone had been diagnosed by a native practitioner in the city of Iaora, who sent him to me for treatment. He had suffered for seven years from stone symptoms, and several hakims had treated him for gonorrhœa. He was most anxious to be relieved from his sufferings as speedily as possible, and next day, being placed under chloroform, I passed into his bladder a No. 15 fenestrated lithotrite, and at once seized a very large stone. I at once perceived that the stone was far too large for such a lithotrite. I then introduced with great facility a No. 32 fenestrated lithotrite (French scale), which Messrs. Weiss and Son had sent me out in September, 1885. My patient had a wonderfully capacious urethra, for it was not found necessary to slit up the meatus before introducing this powerful lithotrite. The bladder I found also very roomy, and not disposed to spasmodic contraction. I seized the stone, but could not lock the lithotrite. I therefore began to chip away at the stone, and gradually wore away some of its shell. After working in this fashion for about five minutes, I withdrew the lithotrite from the bladder, introduced a No. 31 evacuating catheter (French scale), and then applied the aspirator. I then brought away a quantity of white fine débris, proving at any rate that the covering of the stone was phosphatic. I therefore made up my mind to crush the stone at one sitting if possible, for I had many of the conditions necessary to success on my side. I had a powerful and trusty lithotrite and a large evacuating catheter to hand; a very capacious urethra and a roomy bladder to work in; my patient was young; the stone to be attacked was not, I believed, abnormally hard; and last, though not least, I had gained a considerable experience in performing litholapaxy. I therefore reintroduced the large lithotrite, and started afresh. After further chipping away at the stone I eventually wore it down, and soon I was able to lock the lithorite on it, and crushed it at the rim. Once having crushed it, I felt confident of ultimate success, and not to enter into weary details, I may at once state that after three hours and a half of hard work I had extracted a stone, principally phosphatic, weighing over six ounces avoirdupois. The last half hour of the operation was passed in disposing of the nucleus, which I found composed of oxalate of lime, and in searching for pieces of débris lying in the trigone of the bladder. My patient took the chloroform well, and I had no anxiety on this score during the operation. Next day, I found the stone, when dried, to weigh exactly 2804 grs. The nucleus, which I easily picked out from the mass of débris, weighed 100 grs. During the operation I introduced the lithotrite thirteen different times into the bladder, and the evacuating catheter an equal number of times. I exhibited the débris of this stone at the meeting of the British Medical Association held at Brighton in August last. It is, as far as I know, the largest stone which has ever been removed from the bladder by Bigelow's method. To perform an operation of this kind with success is a great strain on the resources of the surgeon who attempts it. He must be ever gentle in his movements, and at the same time persevering and courageous in attack. He must have implicit confidence in the lithotrite which he employs, and he must of all things be patient and in no hurry to finish the operation. Portions of this stone I found extremely hard. On one or two occasions I screwed up the lithotrite with almost the whole strength of my wrist and kept up the pressure. I patiently awaited the result, and soon I had the satisfaction of hearing the snap of the stone as it gave way under the continued pressure of the blades of the lithotrite. I would not, however, recommend an inexperienced litholapaxist to attack such a stone. Had this stone been composed of hard lithic acid or oxalate

of lime, the correct operation for its removal would, I think, have been supra-pubic cystotomy, but being what it was the course which I pursued was doubtless the correct one. The subsequent history of this case was the following:—March 13th (evening): Had completely recovered from the effects of chloroform at 3.45 P.M. One drop of nitro-glycerine was then given. Passed urine at 4.30 and again at 6.20 P.M.; slight pain over bladder and urethra; feels better than before the operation. Evening temperature 102·6°; pulse 96.—14th: Morning temperature 100·2°; pulse 90; slept well; some pain on pressure over bladder and urethra; pain on micturition less than yesterday; colour of urine brown; large deposit of phosphates in urine on cooling; feels much better. Evening temperature 102·2°.—15th: Morning temperature 99·2°; slept well; feels much better. Evening temperature 99·0°.—16th: Pain over bladder and urethra less; passed some small bits of stone along with the urine during the night; sat out in the verandah of the hospital for about half an hour to-day. 17th: Passed some more small portions of stone. Morning temperature 98·4°; evening temperature 99°.—18th: Passed some very fine phosphatic sand; sits out in the verandah daily.—20th: Patient's general health improving; pain in urethra and over bladder on pressure much less.—21st: Passes urine freely and without much pain; has some slight purulent discharge from urethra; has some pain over descending colon.—22nd: Some pain in the left testicle. Placed under chloroform and bladder washed out with saturated solution of boracic acid. No particle of stone could be detected by Sir H. Thompson's sound. No click on using aspirator. 23rd: Had four motions during the night; pain in left testicle much less. Morning temperature 98·4°; pulse 96; sits out in verandah.—25th: Has some pain in region of left kidney; morphia injected.—26th: Pain disappeared from region of left kidney; looks quite cheerful; urine still continues to deposit phosphates on cooling.—27th: Slight pain in passing urine; walks about the hospital grounds. Evening temperature 98·4°.—28th: No urinary symptoms of any importance, except very slight pain in passing urine; urine, however, continues to deposit phosphates; general health much improved.

Remarks.—I left Indore on March 28th on furlough. A letter lately received from India tells me that this patient left Indore for his home the day on which I started for Bombay. When I showed the débris of this man's stone at Brighton in August last, I was under the impression that he had remained in hospital until April 3rd.

That litholapaxy is capable of successfully dealing with stones of considerable size occurring in females, the following case will go to prove.

B——, an old woman aged eighty, was admitted into the Indore Hospital on March 17th, 1886, with stone symptoms which had existed for two years. She had lost control over the bladder for more than one year, and had suffered much from irritability of the same. A stone being found, she was next day placed under chloroform and a uric acid calculus weighing 395 grains removed from the bladder in sixty-seven minutes. The evacuating catheter used was No. 16 (English scale), and the lithotrite employed was No. 14 (English scale). The operation presented no features of difficulty, and the evacuating catheter and lithotrite passed with the greatest ease. When working the aspirator an assistant's finger pressed the meatus of the urethra against the catheter, and thus very little water leaked out between the wall of the urethra and the catheter.—March 19th: Colour of urine pale; it still dribbles away.—20th: Pulse 84; colour of urine brown; no pain over bladder; feels much better.—21st: Has some pain after micturition; passes urine involuntarily only when she moves about in bed; no pain over bladder.—22nd: Is able to retain her urine for two hours at a time; feels very weak.—23rd: Is now able to retain her urine for three hours at a time; she passed some this morning at 6 A.M., at 8 A.M., and again at 11 A.M.—24th: Feels much better; is fast regaining complete power over the bladder.—25th: Allowed to go home to-day, feeling quite well.

Remarks.—Had the stone in this case been twice the weight it proved to be, I do not think there would have been any difficulty in removing it at one sitting.

Were it necessary or profitable to do so, I might relate the history of several more cases wherein I have disposed of stones weighing between 700 and 800 grains by litholapaxy. The cases, however, which I have now recorded, together with many others already reported by Freyer, wherein he has successfully removed very large calculi from the bladder by litholapaxy prove how wide indeed is the legitimate sphere of Bigelow's operation. Sir Henry Thompson is of opinion that a surgeon who is not practically familiar with lithotrity, on meeting with a hard calculus which he cannot readily seize with a lithotrite, will be more likely to achieve a lasting success for his patient by adopting supra-pubic cystotomy in preference to litholapaxy. This may be a wise and sound rule for those who at rare intervals meet with a case of stone, looking at the question from the standpoints of the patient's safety and the surgeon's reputation. But there is another standpoint from which this subject must be viewed, and it is this: Given a patient labouring under the presence of a hard and large stone lying in a healthy and roomy bladder, and an experienced and skilled litholapaxist at hand to treat him, what for the patient is the safest and most satisfactory method of getting rid of such a stone? The record of cases which I have now laid before my readers may supply the answer to this important question. For my part, I think that recourse to Bigelow's operation will best fulfil the requirements of such a patient. Believing, as I do, that litholapaxy is the best method of dealing with the vast majority of stones we meet with in men, women, and children, I must confess that I view with considerable apprehension and misgiving the attempts which are now being made in England by the advocates of supra-pubic cystotomy to apply this revived surgical procedure to the treatment of many cases of stone which would be more appropriately and expeditiously disposed of by Bigelow's operation. And now I leave to the judgment of practical surgeons in Great Britain this record of fifty-eight litholapaxies performed on male children.

St. James's-square.

NOTE ON THE

RELATIVE DIGESTIBILITY OF THE CHIEF ALBUMINOID PROXIMATE PRINCIPLES,

WITH REMARKS ON ITS BEARING ON INVALID DIET.

By JAMES W. FRASER, M.D., C.M. Ed., M.R.C.S.

In the course of some experiments on peptic and pancreatic digestion, I had to work with small quantities of more or less pure albuminoid proximate principles, digesting them with peptic and pancreatic fluids. In estimating the results of these experiments, I was struck by the varying digestibility of the albuminoids, and thought that an account of the results obtained might be valuable.

The experiments were performed with a peptic fluid, consisting of Benger's liquor pepticus, diluted with a ·1 per cent. hydrochloric acid solution, and a pancreatic fluid consisting of the liquor pancreaticus of Benger. The digestion took place in small dialysers suspended each in a beaker containing ·1 per cent. hydrochloric acid solution for peptic digestion; the beaker, dialyser, and contents were kept at a temperature of 37·7° C. (100° F.), and peptic digestion continued for six hours; the liquids, both inside and out of the dialyser being kept in constant slight motion by suitable apparatus. At the end of peptic digestion, the contents of the dialyser were neutralised, and then made alkaline with carbonate of soda, so as to contain ·1 per cent. by weight of the salt, and liquor pancreaticus was added; the ·1 per cent. hydrochloric acid in the beaker was replaced by ·1 per cent. carbonate of soda solution, and pancreatic digestion was allowed to proceed for six hours at 37·7° C. At the end of this time the carbonate of soda solution was replaced by distilled water, and the beaker and contents heated till the temperature in the dialyser was raised to 80° C., so as to kill the ferment. Dialysis was then allowed to proceed for twenty-four hours. Of course, definite and fixed quantities of digestive fluids and external liquids were employed in all cases, and in most an equal quantity of the proximate principle was used. The level of the liquid in the dialyser and in the beaker was kept the same. The dialysed liquids from these periods of the experiment were preserved unmixed, and the results of each are noted under the heads of "peptic digestion," "pancreatic digestion," and "dialysis" respectively. The dialysed liquids were evaporated to dryness in the presence of a small quan-

tity of purified chloride of sodium to make the residue a more manageable substance, and the amount of peptone dialysed estimated as nitrogen by a modified Nessler process, of which full details may be found in a paper on the Action of Infused Beverages on Peptic Digestion.[1] The results in these tables, unless otherwise stated, are expressed as nitrogen; and the amount of nitrogen passing through the dialysers from self-digestion of the peptic and pancreatic fluids, having been previously ascertained by experiment, has been deducted from these results.

Table I. shows the amount and condition of each albuminoid subjected to experiment, the amount of nitrogen and of dry solid contained, whether ascertained by experiment or calculated from the formulæ of former experimenters. Myosin gave so much trouble in preparation that only a very small quantity was used in the experiment with it in the cooked state, and the cooked myosin was prepared by boiling some of the samples contained much less dry solid than others; this depended partly on their physical condition, whether solution or damp solid. The very small amount of cooked myosin has been explained, and that in the case of alkali-albumen depended on the fact that the alkali-albumen had to be in acid solution for peptic digestion, and that this solution had to be rapidly prepared at the last moment to prevent the alkali-albumen changing into syntonin. Cooked serum-albumen was prepared from a solution of purified albumen concentrated at 37·7° C. till it was sufficiently strong to solidify on boiling. It was then heated to boiling in a water-bath and formed a pultaceous mass of granules of coagulated albumen held together by a more liquid substance. It was, therefore, more easily acted on by the digestive fluids than hard-boiled white of egg, as the latter forms a fairly homogeneous substance. No experiment was performed with fibrin, as this forms but a small element

* This result is rather too large, on account of the separation of the fibrinous clot noted in the text.

a solution of the raw substance in salt solution, filtering off the precipitated flakes and using them after pressing between folds of linen. The gluten used was a mere mixture of albuminoids, obtained by washing flour, and was not perfectly free from starch. The uncooked egg-albumen was a filtered solution of white of egg, and therefore contained the salts; and the cooked egg-albumen was hard-boiled white of egg. The raw serum-albumen experiments were performed with measured quantities of ascitic fluid rich in albumen, but containing salts, and in the first experiment a little fibrin. This latter had clotted out in the second experiment, and therefore the figures in Table I. are rather too large for the second case. The other proximate principles used were fairly pure samples. As will be seen from the table, of diet, and alkali-albumen was only introduced on account of its close resemblance to casein.

Table II. shows the amount of the proximate principle (expressed as nitrogen) peptonised and dialysed in each of the three periods of the experiment, and the total of the three. Table III. shows the percentage relation between the amounts dialysed and the amount of albuminoid actually used. In no case did 50 per cent. of the dry solids pass through the dialyser; this depending rather, it is to be believed, on the short period of dialysis than on imperfect peptonisation, for when solids were used in the experiment, in almost every case they were entirely dissolved, and no precipitate was caused by the heating to 80° C. at the commencement of dialysis. The nearest case to 50 per cent. passing through the dialysers is that of cooked myosin (47·15 per cent.), but this seems rather to depend on the

[1] Journal of Anatomy and Physiology, vol. xx$_{II}$ p. 361.

small amount used than on the special digestibility of the substance, for it is to be noticed that during peptic digestion only one quarter as much passed through the dialysers, as in the case of raw myosin, and that it is in the stage of dialysis that the amount is made up[2]. After this the most digestible albuminoid is raw serum-albumen, which in two experiments gave to dialysis 35·24 per cent. and 27·95 per cent. respectively, and the others follow in order: syntonin, 26·47 per cent.; alkali-albumen, 22·14 per cent.; raw egg-albumen, 20·91 per cent.; casein, 17·11 per cent.; cooked egg-albumen (first experiment), 17·9 per cent.; cooked serum-albumen, 17·05 per cent.; raw myosin, 13·91 per cent.; gluten, 9·61 per cent.; and cooked egg-albumen (second experiment), 9·21 per cent. It might have been expected that syntonin, whose digestion is already half done, would head the list, but this is not the case though only raw serum-albumen is fairly ahead of it.

in one case slightly the highest; then follows syntonin—a result which, here especially, might be expected to head the list, and whose secondary position has no apparent reason. The others in order are cooked myosin, raw myosin, cooked egg-albumen (first experiment), casein, gluten, cooked serum-albumen, cooked egg-albumen (second experiment), and alkali-albumen. Therefore the raw albumens appear most susceptible of peptic digestion, and syntonin next.

Turning next to tryptic digestion, cooked myosin heads the list; but the same reasons for regarding the total result of this experiment as doubtful apply to the partial result. Of the more certain experiments, the first, raw serum-albumen, is the highest, with 7·77 per cent.; next comes alkali-albumen, with 7·50 per cent.; followed in order by raw egg-albumen, raw serum-albumen (second experiment), syntonin, cooked serum-albumen, raw myosin, casein, gluten, and the two cooked egg-albumens, these last two not getting

A. Dialysed in first 6 hours.	B. Dialysed in second 6 hours.	C. Dialysed from 12th to 36th hour.	D. Total of A, B, and C.
·00130 grm.	·00132 grm.	·00456 grm.	·00718 grm.

Examining next the amounts of nitrogen dialysed in each stage of the experiment, it is seen that in the peptic digestion stage in no case did 2 per cent. pass through, a small result, amply accounted for by the short period of dialysis (six hours), and by the fact that the dialysable matters had to start from zero and be formed until a sufficient pressure, so to speak, to cause dialysis was obtained. The highest peptic results are with the uncooked albumens, serum being up to 1 per cent. Here the substances most easily soluble in an alkaline menstruum have naturally an advantage in digestion, which accounts for the high positions of the raw albumens, of the alkali-albumen, and of syntonin.

During these two stages peptones had been forming more rapidly than they could pass away through the parchment paper, and had accumulated in the dialysers; and hence, when, the ferment having been killed by heating to 80° C., dialysis was continued for twenty-four hours, a larger proportion of crystalloid matter passed through than in the former stages. These peptones are both of peptic and tryptic formation, as is also the case with those under the head of pancreatic digestion. The largest proportionate result is here again found in the doubtful case of cooked myosin, but it is not very far ahead of raw serum-albumen (first experiment) with [illegible] per cent.; and this is followed by

[2] The relative digestibility of raw and cooked meat cannot be considered settled. E. Jessen (Zeitschrift fur Biologie, 1883) states that 25 grms. of cooked beef left a residue of 17 grms. to 18 grms. after twenty-four hours' artificial peptic digestion, while 25 grms. of raw beef only left 5·5 grms. Lehman (Physiological Chemistry, vol. iii., p. 318) distinctly states that raw meat is more difficult to digest than cooked. The digestibility of meat no doubt depends on other effects of cooking, softening gelatinous elements, &c., but the experiment above, though doubtful, points to the greater digestibility of cooked myosin as having a bearing on the matter.

syntonin, the second raw serum-albumen experiment, cooked egg-albumen (first experiment), alkali-albumen, casein, cooked serum-albumen, raw egg-albumen, raw myosin, cooked egg-albumen (second experiment), and gluten. All these substances, therefore, have valuable dietetic qualities—as was known in many of the cases, indeed, ages before the substances themselves had been distinguished; but their susceptibility to the various digestive fluids varies. Several of them are not ordinarily used as foods at all, as, for example, serum-albumen, raw myosin, syntonin, or alkali-albumen. But among these are the most digestible of the albuminoids, and though they may not be required in every-day diet in that of invalids, some of them would be invaluable.

A formula has been in use for preparing a meat-tea, in which by macerating raw meat with water containing a few drops of hydrochloric acid and some salt a solution containing myosin and syntonin was prepared, but, as it cannot be heated for fear of precipitating the myosin, it forms an unpleasant blood-red liquid, with the taste and odour of raw flesh, and therefore has not become a very popular article of invalid diet. With this exception, and that of foods more or less entirely peptonised, the more soluble albuminoids have been little used for dietetic purposes. Beef-tea, as ordinarily prepared, contains principally extractive matters, and owes the greater part of its nutritive qualities to the deposit of finely divided coagulated albumen and of small portions of muscular fibre which it contains. Now it would be a matter of no very great difficulty to make it almost as nutritious as an equal bulk of solid meat by the addition of roughly prepared albuminoid principles. The white of egg might be added to beef-tea warmed not above the coagulating point of egg-albumen (160° F.)—say not scalding hot. This, indeed, is frequently done, and greatly adds to the value of the beef-tea. But egg-albumen is not the most easily digested of these principles. Dried blood-serum is a commercial article, being easily obtained at the price of about 3*s.* a pound. The preparation of serum-albumen from this mixed substance is easy enough, but it is not to be bought, though possibly if there were a demand the supply would be forthcoming. But the crude article, though only partially soluble, will add greatly to the amount of albumen contained in beef-tea, if macerated in it at a moderate warmth and the undissolved part strained off. Paraglobulin will also be dissolved from the dried serum, if the beef-tea is made fairly salt. The taste of the tea is hardly altered by the serum. Again, if minced raw beef be just covered with very weak hydrochloric acid (four drops of acid to a pint of water) and left to macerate for a night, the liquid strained off and squeezed out of the flesh by wringing in a cloth contains so much syntonin as to become nearly solid on neutralising. Such a solution will remain clear after boiling to remove the raw flavour, and may be used either alone or added to beef-tea or beef extract.

For the sake of showing the advantages of such ...ions to beef-tea, four experiments were performed, rath...ly, but on the same principles as those detailed ab... l in them 10 ccs. of ordinary beef-tea (made with ... d of lean beef to a pint of water), 7·5 ccs. of beef-tea, mixed with 2·5 ccs. of white of egg, 10 ccs. of beef-tea, containing the soluble part of 1 grm. of dried serum and 10 ccs. of hydrochloric acid beef-tea, were respectively digested with the same amounts of peptic and pancreatic fluids as in the other experiments. The results are shown in Table IV. The amounts of nitrogen found are larger than in the other experiments, this depending on the diffusible nature of the extractives in beef-tea and their high nitrogenous equivalents. In the peptic and pancreatic stages plain beef-tea heads the list, and this depends on the less quantity of extractives in the cases where albumens were mixed with the tea, but in the dialysis stage very considerably larger quantities of nitrogen passed through in the cases where egg-albumen and serum-albumen had been added—the egg-albumen slightly leading because more albumen was added in this case than could be dissolved from the 1 grm. of dried serum in that of the serum-albumen. Ten ccs. of beef-tea, with the addition of 20 ccs. of distilled water were subjected to dialysis into similar quantities of distilled water for similar periods to those in the digestion experiments, so as to ascertain if possible how much of the dialysed nitrogenous matter of the beef-tea was derived from extractives. The experiment was performed in the cold,[3] and this, and the absence of the acid liquid in the peptic, and of the alkaline in the pancreatic stage, probably combine to make the result smaller than it would have otherwise been. These results are shown in Table V., and what remains after deducting the total in Table V. from the totals of the beef-tea experiments in Table IV. is shown under the heading lettered E as albuminoid nitrogen—i.e., derived from digested albuminoids not extractives. The hydrochloric acid beef-tea follows far behind the ordinary form, though if all its nitrogen is albuminoid, it is probably more nutritious than ordinary beef-tea, though considerably behind that made nutritive by the addition of albumens.

A few practical hints from these experimental results may be worth noting. First, let it be said, that it is assumed that the digestive powers are not in entire abeyance; for such cases the food given by the mouth or by enemata requires to be in a digested form, and there are many forms of peptonised foods in the market, and many peptonising fluids more or less powerful. But in cases where the digestive powers are impaired but not extinguished, where they may be lost in the stomach but retained in the intestine, or, again, where some obstruction to the passage of solid food into the stomach is causing death by starvation the above experiments may give hints for treatment.

Taking the last first, a case of œsophageal stenosis, malignant or otherwise, in which operation is contra-indicated or declined, and the patient, unable to swallow solids, is sinking. Besides the ordinary endeavours at feeding by the mouth with soups, milk, stimulants, &c., and by the bowel with peptonised enemata, we can add greatly to the nutriment taken by the patient, as long as he can swallow fluids, by simply adding white of egg to his beef-tea at a temperature below that of the coagulation of albumen, or by dissolving in it the albumen of dried blood-serum and filtering off the insoluble part. By this latter means it would not be difficult to dissolve as much as 20 per cent. by weight of albumen in the soup, and so make it as nutritious as an equal weight of meat. Again, syntonin might be made and used alone or dissolved in the soup, and has the advantage that it can be heated to boiling and the raw flavour of the uncooked albumens avoided. Then, when the stomach digestion is impaired and our desire is to stimulate a somewhat lazy organ to action, not to humour it in its laziness by giving it predigested food only requiring absorption, in such a case the raw albumens stand pre-eminent as feeding substances, all of them easily acted upon by the stomach, but all requiring full digestion. They may be given in beef-tea or soups, or in coffee or chocolate, or raw eggs may be eaten, when, as Dr. Hodges said in a lecture recently delivered before the Boston Medical Improvement Society, they should be sucked out of the shell or broken into a glass and drunk out of it; not beaten up into a froth, as they usually are, which carries down entangled air into the stomach, causing flatulence and preventing that free mixture of the digestive fluid with the albumen which is so desirable for perfect digestion. But if the stomach be weaker and require some humouring, the syntonin solution will still give it enough work to do to avoid entire inactivity. The beef-tea, in which the albuminoids are recommended to be dissolved, has been shown to have peptogenetic properties, and would therefore stimulate the stomach secretion; and though Sir W. Roberts[4] has shown that it retards artificial digestion, yet he has also shown that this can be avoided by using a little additional acid in digestion or by removing the organic salts of the beef-tea by dialysis, and one or both of these conditions will be fulfilled in stomach digestion.

The experiments with casein and gluten appear to show that there are very few worse foods for a delicate stomach than the usual bread and milk, for, as has been seen, the stomach only dissolves about ·6 per cent. of these principles in the same time that it dissolves nearly 2 per cent. of serum-albumen. And the casein in the experiment was in an easier form for digestion than that in which it is usually presented to the stomach, for as used it was in a fine granular form practically freed from fat with alcohol and ether; while cows' milk in the stomach forms dense solid clots, rendered all the more insoluble by the fat, which forms the greater part of their bulk. True, the bread acts as a diluent to the clots, breaking them up, with passages for the gastric juice; but still it is evident that for digestion by a delicate stomach bread and milk does not form an ideal food. Whey,

[3] The dialysis of crystalloids through animal membranes increases proportionately with the temperature (Graham, Zeitsch. für Physiolog. Chemie, Band iv., p. 537).

which contains all the lact-albumen, so a globulin, is a mildly nutritive fluid and easily digested, for the lact-albumen is the same as serum-albumen. When the stomach digestion is paralysed in acute diseases—a state which, as Sir W. Roberts states,[5] may be diagnosed by the inability to take solid food—the pancreas often retains its power of secreting a peptonising fluid, and the stomach becomes a mere conduit to the duodenum. When such a state occurs, it may not be desirable, for other reasons, to get much nitrogenous food assimilated, for as Auerbach[6] has shown, a nitrogenised diet increases the acidity of the body, and might, in such a case, tend to produce an attack of gout, as was mentioned by Dr. Allchin.[7] But in cases where it is desired to feed the patient through the intestine, the substances noted above as soluble in alkaline fluids, and therefore easily acted on by the pancreatic juice—viz., raw albumens, syntonin, or alkali-albumen,—may be used alone or dissolved in some meat tea.

Hull.

TWO RARE CASES OF ACUTE INTUSSUSCEPTION.

BY JOHN THOMAS, M.R.C.S., L.R.C.P. LOND.,
ASSISTANT-SURGEON TO DINORWIC QUARRIES HOSPITAL.

THE following cases I attended whilst assisting Dr. Smith, of Lewisham-road, London.

CASE 1.—On February 11th, 1886, at 11 P.M., I was summoned to see a child described as suffering from "fits from teething." The history given by the mother was briefly as follows: John C——, aged sixteen months, in good health, was suddenly attacked with great pain in the abdomen and diarrhœa on the 7th whilst at dinner. The diarrhœa, heedless of domestic remedies, continued until the 9th, when the little boy was better for some hours, and then relapsed into a worse condition. On the 10th he strained and passed nothing but slime. Towards the evening vomiting set in, and continued all night and next day until seen by me. In the afternoon of the 11th blood poured out from the body, whereupon the mother wrapped up the child from fright. I found the boy looking collapsed; pulse 146, and not compressible; abdomen empty and asymmetrical; a distinct hollowness to the right, and fulness to the left, of the median line. The infantile buttock garment was soddened with much dry and moist blood. A smooth resisting cylindrical tumour was felt beginning abruptly a little above and to the left of the umbilicus, and passing to the left became indistinct; another tumour passed downwards from the splenic region towards the pelvis—in short, corresponding to the anatomical tract of the colon. Per rectum, within easy reach of my finger was a smooth hard tumour unconnected with the walls, and bimanually impulses were conveyed to the iliac abdominal tumour. I reversed the child's position in bed, placing the pelvis high on the pillow, then kneaded the tumour from above downwards for about fifteen minutes, and administered a draught containing two minims of laudanum. I failed to improvise an insufflating apparatus.

On the 12th, at 9 A.M., I arrived with instruments for active interference, but was surprised to find the little one strongly resenting my interest in him. He had just passed a small liquid motion, clayey in colour. The abdomen was symmetrical and slightly tympanitic.

Remarks.—I trust the extreme rarity of natural subsidence of an intussusception of any magnitude is sufficient excuse for a contribution on a subject fairly thrashed out. "I have not found any case recorded in which spontaneous return of a well-recognised intussusception occurred" are the words of Mr. Jonathan Hutchinson,[1] and are fully endorsed by Mr. George Pollock in Holmes' "System of Surgery" (1883). I am not aware of any other recorded case. The hollowness of the right flank, *signe de Dance*, "is of little or no value."[2] In this case it tends to support the view that the first portion of the colon is displaced. The factors which co-operated in bringing about cure are probably the following:—(*a*) prostrate condition of the child; (*b*) impulses given to the intussusceptum in the rectum by the finger simulating more or less the obsolete treatment with bougies; (*c*) descending or downward kneading probably played an important *rôle* in undoing a folded sheath, so that the two outer layers of the intussusception came into a nearly plane contact—clearing the course, so to speak, for the muscular element; (*d*) laudanum; and (*e*) pre-eminently the smooth muscle of the gut acting under favourable circumstances. Had I continued the kneading the intussusception might have been reduced when first seen. *Experientia docet.*

CASE 2.—E. R ——, a fine healthy boy, aged five months, was suddenly seized with an unusual fit of crying and vomiting on March 29th, 1886, at 6 A.M.; straining and passing scanty motions tinged with blood soon followed. Castor oil was given by the mouth and rectum, and the child's abdomen became swollen from the onset of the symptoms. The preceding is the mother's story.

When seen on March 31st, I found the child's abdomen greatly swollen and tympanitic, globular in form, and the greatest measurement was around the pit of the stomach. The child cried and strained violently and simultaneously; in the intermission he was quite calm and did not object to any manipulation. Per rectum, I indistinctly felt something. The anus was dilated with two teaspoon blades, and when the child strained a darkly congested body like the os uteri (this is not a new simile, but a good one) appeared, and quickly retreated when straining ceased. Temperature 99°; pulse 140, fairly full. With a six-ounce injection bottle which was at hand I cautiously injected lukewarm water, some of which returned. I filled the bottle a second time, and when half emptied under moderate pressure a rumbling noise was heard in the abdomen. No water returned, and half a teaspoonful of brandy was given to the child. I felt hopeful, but far from confident, there being no straining and the infant taking the breast without vomiting. In an hour and a half death supervened, sixty-six hours from the onset of the attack.

Necropsy.—Enormously distended coils of intestine protruded as far as the abdominal cavity opened; the adjacent coils were adherent through small greyish patches of lymph. In the pelvis was about half a tumblerful of water. It was most difficult to reach the intussusception, and manipulation of it was almost impossible without first letting the gas out of the intestine. There was a descending meso-colon. There were no adhesions in the intussusception, which extended from the spleen to the first portion of the rectum. The sheath was considerably folded, especially near the neck of the intussusception; it (the sheath) was thickened in the part most distant from, and thinned in the part next to, the meso-colic attachment; there was a rent in the thinned portion. The middle layer was three-eighths of an inch thick opposite to its fold, and of the thinness of paper near its fold. The inner layer was deeply congested.

Remarks.—The involution commenced in the ileum and passed through the ileo-cæcal valve; the cæcum and the ascending and the transverse colon then contributed to the growth of the invagination. This form of intussusception is the most rare, and has been termed "the ilaca-ileo-colica" by Leichtenstern.[3] Miss Lane very kindly made for me the appended sketch, which shows well the one-sided apical os and the ileo-cæcal aperture higher up. Post-mortem

[5] Op. cit., p. 68. [6] Arch. f. Path. u. Phys. Anat., xcviii., 3, p. 512. [7] THE LANCET, vol. i. 1885, p. 418.

examination again taught the advisability of emptying the bowel of its gases as soon as the peritoneal cavity is reached, had laparotomy been performed in such a case. Emptying the bowel with an aspirator, such as Dieulafoy's, would ensure rapid evacuation and bottling up of the obnoxious gases. Traction on the entering layer of the intussusception would not reduce it, but by fixing the entering layer with one hand and unfolding the wrinkles of the sheath with the other, beginning from below and finishing with the wrinkles of the "neck," reduction became possible and easy. Rupture of the gut must have occurred early in the case during one of the peristaltic squalls, and the position of the rent is highly suggestive. The attenuated condition of the sheath in the neighbourhood of the meso-colic attachment—the most fixed part—is hardly due to circular stretching of the walls of the gut, for the intussusceptum is not enough to fill it; it is probably not due to longitudinal stretching, for the folds could have so easily supplied the need. The thickening of the part most distant from the meso-colon, I need hardly remind the reader, is accounted for by œdema and hæmorrhage; but where is the muscle fibre of the thinned portion gone to? In the gravid uterus at term, when it cannot get rid of its contents in due time, it is well known that retraction of the smooth muscle towards the fundus uteri takes place to a dangerous degree, and during one of the uterine contractions "snap" goes a rent in the attenuated part below the "ring of Bandl," unless art or nature brings the case to another issue. Now, if the thinning of the one side of the bowel has contributed to the thickening of the other side, it is a parallel to what obtains in the uterus.

Llanberis, North Wales.

IMPERFORATE ANUS AND RECTUM; RECOVERY.

By R. HERBERT BARKWELL, M.D.

THE subject of this malformation, an ill-nourished male child, had been born twenty-four hours when, on June 18th, I was called to see it. The case being complicated, instruments had been used at the birth, causing facial paralysis. I was informed that there had been no evacuation from the bowels. I found the anus imperforate, and proceeded to operate in the lithotomy position, I dissected along the mesial line, in the natural position of the anus, to the depth of 2½ in.; then with a trocar and cannula I perforated ½ in. further without encountering the bowel. Failing here, I decided to perform colotomy on the following day; in the meantime the perineal incision was washed with a solution of carbolic acid, and dressed with carbolic lint. On June 20th, chloroform having been administered, I made a transverse incision about one finger's breadth above and parallel to the crest of the ilium of the left side, and 2 in. in length. The skin and superficial and muscular tissues were carefully divided on a grooved director, and the peritoneum incised to the same extent. The hæmorrhage was copious, and required a sponge soaked in a solution of carbolic to be constantly used, the instruments being also kept wet with it. Recognising the descending colon by its large, dark-greenish, and distended appearance, as compared with the small and light appearance of the smaller intestine, with a polypus forceps I picked and brought it up, outwards and backwards, to the margin of the incision at its posterior part; four curved needles with silver wire fixed the intestine to the abdominal wall; the colon, together with the peritoneum, was sutured at four points to the margin of the wound to prevent it from slipping back and to prevent meconium from escaping into the abdominal cavity. The most projecting part of the colon was now opened; no meconium having escaped, I introduced the broad end of a director and brought away some of a dark-green colour. The abdominal incision being larger than was necessary, I used, to close it up to its margin, three sutures, two anteriorly and one posteriorly. The infant was now given a warm bath, wiped perfectly dry, and placed before the fire, after which it revived considerably from the effect of the chloroform, which had been continued from the commencement to the close of the operation, its movements causing some meconium to escape. The wounded parts were then washed with [illegible] with carbolic li[illegible]

During the first [illegible] the mother's supply of milk being deficient, artificial milk was substituted.—June 20th: Wound looks well; washed and dressed with carbolic lotion and lint; infant vomited at intervals during night, colour greenish yellow; prescribed three grains of nitrate of potash, six grains of bicarbonate of soda, ten minims of tincture of digitalis, six of tincture of belladonna, with one ounce of water, half-teaspoonful doses to be taken every three hours. At 10.30 P.M. the vomiting had ceased, and a little milk given was retained; motion passed of a dark-green colour; re-dressed the wound; no sign of pus. 21st: No motion during night; introduced a grooved director, and, holding the child with left side downwards, a fair quantity came away; commenced taking mother's milk; goes on favourably.—22nd: Meconium continues to discharge freely, but in the evening director again required to render discharge free; vomiting returned.—23rd: Condition the same as on the 22nd.—24th: Two sutures removed; there continues a healthy discharge of fæces each time wound is dressed, which I continue twice a day; margins of wound looks inflamed, due probably to irritation of sutures.—26th: One suture removed; wound improved. At 10.30 P.M. another suture was removed; wound looks well.—27th: Infant improves in every way.—28th: Removed remaining suture; re-dressed wound.—29th: Wound looks well and healthy; no discharge; washed and dressed as usual. 30th: Fæces have become small and solid; wound assuming an elliptical form; perineal wound quite healed.

July 1st: Infant photographed; bowels moved freely.

July 3rd.—Finding the bowels inactive, I prescribed liquor sennæ dulce (two drachms), liquor hydrarg. perchlor. (one drachm), and an ounce of water; one half-teaspoonful p. r. n.—4th: No motion passed; one drachm of castor oil given; not succeeding, I removed the fæces again with director, and ordered one drachm of castor oil at 11 P.M. 5th: No motion; repeated castor oil (one drachm and a half) and liquor sennæ dulce (twenty minims); bowels acted slightly. In the evening repeated castor oil (one drachm).—6th: Milk slightly returns; bowels acting better, but not freely. Gave liquor sennæ dulce again. Has not taken the breast during the day; skin looks drawn; infant peevish and ill.—7th: Infant somewhat better; resumed the breast; still vomiting. The bowels not acting freely, I ordered calomel in one-grain doses to be given night and morning. Wound is now perfectly healed.—8th to 12th: Infant is progressing favourably; calomel, with castor oil, continued at intervals. 12th to 15th: Less aperients required; half-grain doses of calomel to be repeated at night only. From the 15th I commenced giving twenty-minim doses of cod-liver oil, and also continued to have the chest rubbed with it daily. From this date everything has gone on satisfactorily, the infant gaining strength rapidly.

The temperature never exceeded 100° F., and to the end of the convalescence remained nearly normal. The strictest antiseptic precautions were observed throughout the case. I have been somewhat prolix in details of the after-treatment, because I consider that the ultimate success of an operation chiefly depends upon this being carried out. In conclusion, I have to observe my operation is a repetition of Amussat's, slightly modified on the method of Littré being more adapted to suit the exigency of this case. I wish to acknowledge my indebtedness to Dr. Richardson, who during the operation kindly gave me every assistance.

Lavender-hill, S.W.

HOSPITAL SUNDAY.—The Lord Mayor has received from Sir P. Cunliffe Owen a letter stating that he was requested by the Prince of Wales, Executive President of the Royal Commission for the Colonial and Indian Exhibition, to enclose a cheque for £104 5s. 8d., being the amount received from Oct. 8th to Nov. 10th in Dr. James Aveling's "Mechanical Begging Boxes" at the Exhibition for the Hospital Sunday Fund. This makes a total of £404 5s. 8d. resulting from this ingenious mode of collection.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—The monthly meeting of the members of this Association was held on the 17th inst., Dr. Kenyon in the chair, when it was resolved that Dr. Vacher, Dr. Kenyon, and Dr. Hope be appointed a subcommittee to consider a letter from the President of the Metropolitan Society of Medical Officers of Health inviting medical officers to form themselves into one general society, and to report thereon at a future meeting.

Nulla autem est alia pro certo noscendi via, nisi quampluriumas et morborum et dissectionum historias, tum aliorum tum proprias colligas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

POPLAR AND STEPNEY SICK ASYLUM.

AN UNUSUAL CAUSE OF EMPHYSEMA; NECROPSY; REMARKS.

(Under the care of Mr. W. H. PEARCE.)

SURGICAL emphysema is usually produced by injury to the respiratory or alimentary tracts, and of these wound of the former, as is well known, is by far the most common cause. In connexion with the digestive tract, the situations in which it has been met with are, over the abdomen after wound of the intestine, and in the pelvic region after damage to the rectum or perforation of its wall by ulceration. Emphysema is also found in other conditions, such as wounds of a crushing or lacerating character, chiefly in the limbs, and also accompanying decomposition of parts. In the following case a most unusual condition was found at the post-mortem examination (*q. v.*), and the extravasated air had followed the course taken by the escaped air in some instances of injury to the root of the lung.

Wm. P——, aged forty-four, was admitted in a dying state on Monday, Oct. 25th, at 5 P.M. From the little information that could be gathered from the man himself or his friends, it was learned that he had always enjoyed good health and had followed his usual employment until the previous Saturday. He admitted being a "free drinker," and on Saturday night he had been "the worse for liquor," but, so far as he knew, he was not injured in any way. He did not feel well on the Sunday, and remained in bed until late in the afternoon, when he dressed and went out for half an hour. Soon after his return he "began to swell, and his breathing got bad." He had urgent dyspnœa, his skin and mucous membranes being very blue, and his pulse quick and feeble. His face and neck were much swollen, especially on the left side, and on palpation this was found to be due to emphysema of the subcutaneous connective tissue, which on further examination could be traced all over the trunk as low down as the hips, and for some distance down the arms. He denied having sustained an injury, and on careful examination by Mr. Bostock and Mr. Pearce, no injury to the ribs or respiratory tract could be made out. The chest wall moved very little in respiration, the breathing being for the most part diaphragmatic. Percussion elicited a resonant note all over the chest, though at the bases and in the axillæ the note was flatter than that obtained at the anterior and upper part of the lungs. In the former situations there was almost an entire absence of breath sounds on both sides in the lower half of the chest, but in the former air entered freely. The heart's apex could not be made out. His breathing gradually became worse, and he died somewhat suddenly three hours and a half after admission.

Necropsy, forty hours after death.—The body was that of a stoutly-built, well-nourished man, of middle age. On opening the chest there was no fracture or other injury to the chest wall, but both pleural cavities contained a considerable quantity of fluid, the lower lobes of both lungs being compressed and airless. Much recently effused lymph covered the surfaces of the visceral and parietal pleuræ on both sides. On clearing away this, and separating the lower part of the left lung from the pericardium, a collection of undigested food was found outside the œsophagus, occupying the posterior mediastinum and surrounded by emphysematous connective tissue, which could be traced up the spine to the root of the neck. The food had escaped through a ragged slit-like opening of an inch long, and situated vertically in the œsophageal wall about an inch and a half from its lower end. Passing downwards in the substance of the wall of the œsophagus was a sinus, which connected the opening with a small circumscribed abscess (about the size of a hazel-nut) situated in the wall of the stomach along the lesser curvature close to the cardiac orifice; this again opened into the cavity of the stomach by a small opening, so that gas or air could pass in freely from the œsophagus or stomach. A small quantity of pus was found in the small abscess in the stomach, but there was no sign of any in the mediastinum. There was no trace of ulcer in the œsophagus, the opening being a mere ragged slit, with black unhealthy-looking edges, outside which the gullet appeared healthy; but here doubtless the mischief must have begun and an abscess formed, the pus burrowing down and finally discharging into the stomach, the œsophageal wall giving way either at the same time or later.

Remarks by Mr. PEARCE.—As to the cause of the abscess, the only thing that suggests itself to my mind is the lodgment of a foreign body, such as a spicule of bone; but there seems to have been no symptoms up to the time when the œsophageal wall gave way, and gas or swallowed air escaped into the mediastinal connective tissue. I did not make out before the necropsy the considerable amount of double pleuritic effusion, believing as I did that the cause of the emphysema must be due to injured lung from obscure fracture of the ribs, and that the compression was being exercised by internal hæmorrhage.

ROYAL HOSPITAL, PORTSMOUTH.

LACERATED WOUND OF THE KNEE, FOLLOWED BY TETANUS TWENTY-TWO DAYS AFTER THE ACCIDENT; TREATMENT BY CHLORAL HYDRATE; RECOVERY; REMARKS.

(Under the care of Mr. HENRY RUNDLE.)

W. C——, aged fifteen, a healthy lad, was admitted on Dec. 8th, 1885. Whilst holding on to the back of a cart he slipped and was dragged along the ground, sustaining a lacerated wound, about four inches in length, over the left knee. There was no fracture. The wound was washed clean from gravel and dirt, and dressed with carbolised oil. Five days after admission suppuration occurred; openings were made, and a drainage-tube inserted for twenty-four hours. The wound was granulating healthily, when on Dec. 30th symptoms of tetanus appeared, well-marked risus sardonicus, and seven or eight attacks of clonic spasms during the day. He swallowed with some difficulty. Breathing easy. Temperature 99°; pulse 130. He was ordered a free purge and chloral hydrate in ten-grain doses every four hours, and removed to a quiet and darkened part of the ward.

Jan. 1st. Experienced great relief after medicine. Spasms less frequent; abdominal muscles hard; wound suppurating; poultices applied. Milk, beef-tea, and juice of raw meat to be given between the spasms.

2nd. A quiet sleep after each dose of medicine, which he asks for "to keep off spasms." Temperature 98·2°. Three or four spasms during the day. Complained of difficulty in passing water, which was relieved by hot fomentations.

3rd. Improved. Three spasms during the day. Abdominal muscles still hard and contracted.

During the next six days the spasms diminished both in frequency and severity, and ceased on Jan. 9th. The chloral hydrate was continued, but less often, up to Jan. 19th. From this time the wound continued to heal, and he was discharged well on March 16th.

Remarks by Mr. RUNDLE. The boy being able to swallow, although with difficulty, was a favourable symptom. In the treatment of tetanus, it is essential to keep up the strength by giving nourishment with a liberal hand, milk and juice of raw meat being the best food. I think there can be no doubt that the medicine aided materially in the recovery of the patient, for the chloral hydrate not only induced sleep, but, by diminishing the reflex irritability of the spinal cord, lessened the frequency and violence of the spasmodic attacks. The boy asked for this medicine before it became due, as he was afraid of the spasms recurring, and he was so convinced of its efficiency to keep them off. The other points of treatment were free purgation and keeping the patient as quiet as possible, free from any cause of excitement, including light and sound. A point worth noting was the low temperature; once only did it reach 99°, being at other times normal.

MULTIPLE MELANOTIC SARCOMATA; DEATH; NECROPSY.

(Under the care of Mr. RUNDLE.)

E. Y——, aged forty-five, was admitted on Feb. 4th, 1886. There was no history of tumours or malignant disease in the family. He has had eight children

The present illness commenced six months ago, when she first noticed a lump like a pea in the skin under the right breast. This grew rapidly, but as it did not give her any pain she delayed seeking advice until a week before admission. In the right breast there is a semi-fluctuating, purplish tumour, movable on the thorax, the size of a large orange. The left breast has the appearance of extravasated blood, evidently containing a growth. Other small tumours, six in number, ranging in size from a walnut to a pea, and having the same bruised appearance, exist over the sternum and in the abdominal wall.

Feb. 11th.—The right breast was excised, and three small tumours on the abdomen. Free haemorrhage during the operation.

16th. Wound of small tumours healed, but that of breast breaking down and discharging. Patient weaker and losing flesh.

The progress of the case was unsatisfactory. The granulations over the right breast became gelatinous in appearance, and the other growths increased in size, and fresh ones appeared on the abdomen. The patient sank gradually, and died from asthenia on April 20th. A microscopical examination of the growth removed showed spindle and fusiform cells pigmented.

Necropsy, forty-eight hours after death (from notes by Mr. C. C. Claremont). Body emaciated. In the situation of the right mamma is a well-defined fungating tumour, covering an area of about six inches square, and reaching to the middle line. The tumour at the surface is black, softened, and seems to be mainly slough. The deeper part, reaching down to the periosteum, is white, soft, and brain-like The ribs are unaffected. There is a tumour in the left mamma. Under the skin of the trunk and thighs are fourteen tumours, soft, sharply defined, and some fluctuating. Dissection shows some of them to be of the same white, soft material as the large tumour; others are more or less pigmented with black material, and some contain broken-down blood-clot. They vary from the size of a hazel-nut to that of a walnut. Abdomen: The transverse colon, being distended and translucent, exhibits several black patches the size of a finger-nail. In connexion with the omentum are four or five tumours, more or less pigmented, and similar to the subcutaneous ones. The mesentery presents at least a dozen of these small tumours, which appear to be covered by peritoneum; some are free from pigment. In front of the left kidney is a tumour the size of the fist, mottled white and black, and containing a cavity of broken-down blood-clot; similar but smaller tumours were found at the lower end of each kidney. A small patch of pigment in left supra-renal capsule. Liver and kidneys markedly fatty in appearance. Thorax: Small, partially pigmented tumour in the anterior mediastinum. Lungs emphysematous and congestion posteriorly. Heart walls fatty: valves healthy, but not opened. All the tumours examined were encapsulated.

CRUSH OF LEGS BY TRAM-CAR; DOUBLE AMPUTATION THROUGH THE KNEES; RECOVERY.

(Under the care of Mr. RUNDLE.)

Henry D——, aged ten, was admitted on Oct. 17th, 1886. Whilst crossing the road he was run over by a tram-car and sustained extensive compound comminuted fractures of both legs, the soft parts being much lacerated. On admission the boy was conscious, but much collapsed. Both legs were removed at once a hand's breadth below the knee, by circular operation on the right and flap operation on the left.

Oct. 18th.—Restless night. Pulse 140; temperature 103°. Very sick.

19th.—Still very sick. Pulse 130; temperature 103·2°. Very restless and delirious in the night. Hypodermic injection of morphia (one-sixth of a grain) at 9 P.M.

20th. Slept fairly well. Pulse 112; temperature 100°. Retains food. Some of the stitches separated, and stumps discharging and inclined to slough.

26th.—Pulse 112; temperature 99·3°. Constitutional disturbance much less. Sloughs from flaps removed.

From this date he went on well. The flaps were brought together by strapping, and iodoform dusted over them, and by Nov. 30th the stumps were nearly healed.

AT an inquest held at Newport, on the 7th inst., on the body of a woman who had died from taking a dose of liniment instead of the mixture which he had prescribed for her, the jury returned a verdict of not guilty, and a future meeting which he divided the tendo Achillis; and rapid extension,

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Hypertrophy of Thigh and Leg.—Cervical Pachymeningitis.—Lupus of Larynx.—Syphilis of Tongue. Rare Syphilis of Face.—Talipes Equinus.

A CLINICAL meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Mr. BULL showed a boy with great enlargement of the left thigh and leg, which began six months ago. There was no evidence of tumour, phlebitis, or arterial disease. The thigh measured two inches more in circumference than the right side. The swelling was probably due to lymphangiectasis. There was no evidence of chyluria or albuminuria. It was not a case of asymmetry. The patient had never had any deep-seated phlebitis or attacks of erysipelas or erythemata.—The PRESIDENT asked whether there was any difference in the temperature of the two sides. Mr. MARMADUKE SHEILD remarked that there seemed to be an elongation of the femur. Was this so? Mr. J. H. MORGAN considered with Mr. Sheild that the case was of congenital origin. Dr. A. MONEY inquired for filariæ sanguinis hominis. Mr. NOBLE SMITH inclined to the view that the hypertrophy was congenital. Mr. BULL said there was no difference in length or temperature in the two limbs.

Dr. ORD showed a specimen of Chronic Hypertrophic Cervical Pachymeningitis, in a footman aged twenty-six. Last Christmas (1885) he was seized with pain, stiffness of neck, sickness, and constipation. Temperature 103°; pulse 95. At another time the temperature was 101·2°; pulse 72. He had some shivering fits, which bore a resemblance to ague. He had delirium at times, and was very much weakened. Later he gained flesh and strength. In May of this year there was no fever, but great loss of power and wasting of muscle, and loss of sensation in the arms. The legs were in a state of spasmodic paraplegia. Two muscles have escaped to a large extent—the anterior part of the deltoid, and the biceps. There was some exaggeration of extensor tendon reflexes. Mechanical irritability of the muscles was excessive. The electrical state of the muscles was that of the reaction of degeneration. Sensation has improved, and there was some improvement in the power of the arms and legs. A claw-shape of the hands had developed since May. There was considerable curvature of the spine. Distressing attacks of diaphragmatic paralysis (?) had occurred of late. The skin of the fingers was wasted and smooth—somewhat glossy. A gradual osteo-arthritis had developed in several joints in the hand. There was no history of a chill, or injury, or syphilis. He advanced this case as an illustration of the hypothesis that a good many cases of chronic progressive affections of joints are dependent on altered states of nutrition of the spinal cord. The PRESIDENT inquired whether the optic discs were affected.—Dr. BEEVOR thought it threw some light on the localisation of groups of muscles in the spinal cord. The facts of this case strengthened the results of experimental observations.

Dr. A. MONEY remarked on paralysis and dilatation of pupil, associated with atrophy of interossei.—In reply, Dr. ORD said the optic discs were natural, the pupils were somewhat dilated, and the left larger than the right. There were no evidences of abnormality in the pulse.

Dr. ORWIN showed a case of Lupus of the Larynx in a woman, associated with the same disease of face and nose.

Dr. COLCOTT FOX showed a case of Lupus of the Larynx associated with lupus of the face, palate, and scalp, in a boy aged seven years. Kaposi said that autochthonous affection of the larynx with lupus was unknown. Dr. FELIX SEMON said that papillary excrescences and ulceration of the epiglottis were to be seen. He did not think lupus of the larynx so rare. Chiari had collected forty cases. In perhaps 5 to 8 per cent. of cases of lupus the larynx had been involved.—Mr. LENNOX BROWNE agreed with the remarks of Dr. Semon.—Dr. MORELL MACKENZIE had noticed the stridor in Dr. Orwin's case a month or more ago, and could not therefore set it down to the treatment by dilatation.

Dr. ORWIN showed a specimen of Syphilitic Affection of the Tongue in a boy aged nine, in whom there were no other evidences of congenital syphilis.

Mr. NOBLE SMITH showed severe cases of Talipes Equinus,

with immediate reduction was followed by better results than obtained when the tedious method was adopted. The rapid method was one of tenotomy and immediate stretching.—Mr. J. H. MORGAN said he had been accustomed to treat cases in this fashion for many years past.

Mr. MARMADUKE SHEILD showed a case of Syphilis in a woman with a large fungating mass about the angle of the nose, which was believed to be the source of infection, but it had no resemblance to an ordinary chancre.

ACADEMY OF MEDICINE IN IRELAND.

Ovariotomy.—Nephro-lithotomy.

AT a meeting of the Surgical Section on Nov. 12th, the President, Sir WILLIAM STOKES, delivered the inaugural address, which was published in our issue of the 20th ult.

Mr. F. V. MACDOWELL read notes of a cases of Ovariotomy performed by him in Baltinglass Infirmary. The operation was performed by making an incision from the umbilicus to the pubes. The cyst was found so dense that the trocar would not enter it. An incision was made into the tumour, and the cannula, being connected with indiarubber tubing, was well embedded in the cyst, and secured in the usual way with spring hooks. Owing to the numerous adhesions, it was found necessary to enlarge the abdominal opening by three inches around and above the umbilicus. Twelve pints of amber-coloured fluid were drawn off. The pedicle was clamped, divided, treated with actual cautery, and, by a modification of the extra-peritoneal method, secured in the lower part of the abdominal opening, and retained there by harelip pins passing through it as well as the abdominal wall, the pins being retained *in situ* by carbolised catgut. The wound and pedicle were maintained perfectly aseptic by means of regular applications of iodoform. The operation was performed on March 31st, 1886. The patient moved about the ward within three weeks from that date, and in the sixth week walked one mile to the operator's residence on her way home.—Sir WM. STOKES congratulated Mr. MacDowell on his success, and hoped that many of his colleagues in the country would in like manner bring before the Academy the results of their practice.

Mr. KENDAL FRANKS read a paper on Nephro-lithotomy, and reported the case of a man aged twenty-eight from whose left kidney he had excised a large stone on the 6th of May last. The case made a satisfactory recovery, and was the first case of the kind in which the operation of nephro-lithotomy had been performed in Ireland. The history of the case dated back six years, when the patient, after a severe febrile attack, had hæmaturia, which lasted for three months. The symptoms he presented, from which the diagnosis was made, were: pain over the lower part of the left side of the thorax, and over the region of the left kidney, shooting downwards to the crest of the ilium and to the left groin. There was no testicular pain; tenderness existed over the last rib and below it on the left side on pressure; there were large quantities of pus in the urine, which, though fetid, was always acid. Added to these symptoms, the history of the case, the absence of bladder symptoms, and the absence of pyriform cells in the urine assisted in the diagnosis. The kidney was reached by the lumbar incision; the stone was felt, completely filling the pelvis, and was excised through an incision in the substance of the kidney. The calculus was friable, composed of phosphate of calcium, carbonate of calcium and ammonium magnesium phosphate, and weighed 171·3 grs. when washed and dried. It was removed piecemeal, being too large to extract entire. The lumbar wound healed by first intention, the site of the drainage-tube continuing to discharge urine for four weeks. The patient had returned to work several months ago; he was free from pain and in good health. He still passed some pus with the urine.—Mr. BARTON, having assisted in the operation, was impressed with the fact that it marked a new era in the progress of urinary surgery. Where a satisfactory diagnosis was established, it was the surgeon's duty to open the loin and expose the kidney, and then follow the lines of procedure indicated by Mr. Franks. The diagnosis was the first point of practical interest. He emphasised Mr. Franks' observation that the pain located in the loin was most reliable. The condition of the urine, too, left no doubt of calculus being present, surrounded by inflammatory exudation and pus.—Mr. THOMSON said the difficulty that must always present itself in such cases was that of diagnosis, and not the removal of the calculus, once its presence was made clear. He had seen two operations on the kidney, and he had another case under observation. In one there was a large distinct tumour on the left side. All the symptoms referable to stone in the kidney were present; but the organ was too large for removal through the lumbar incision. The tumour was removed and the stone found; but there was also a stone in the other kidney, and the result was fatal. In a proportion of those cases there was a great tendency to infection of the second kidney, and when one was removed it was not always certain that all the mischief had departed; indeed, the patient might be worse off than before. Another point of importance was in reference to the incision. Where the kidney was not specially enlarged so as to present a tumour in the abdominal cavity, the lumbar incision was attended with least risk. In one case of stone which he saw, the kidney was so large that there could be no question of the futility of attempting to remove it through the lumbar incision. The only proper course would be that adopted by Knowsley Thornton of removing the tumour by abdominal section and draining the abdominal cavity through the loin.—Mr. FRANKS, in reply, said of course Mr. Thomson referred to cases of nephrectomy, and not of nephro-lithotomy.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE second Meeting of the session was held in the Faculty Hall on Nov. 17th. It was agreed that the meetings be held hereafter on the fourth Wednesday in each month.

Fomentation Bag. Dr. SLOAN exhibited an indiarubber bag with an afferent and efferent tube, whereby uterine and vaginal fomentation might be maintained during pleasure. He said the invention was due to Dr. Alexander Robertson, one of the physicians to the Royal Infirmary. Water from 110° to 115° could be used, and for as long as half an hour at a time. The effect was found to be very grateful in inflamed conditions.

Blighted Ovum. Dr. ABRAM WALLACE exhibited a blighted ovum, which old authors might have called a mole. The patient from whom it had come menstruated in June last, from which time she dated her pregnancy. At the end of August she noted a slight brown discharge. In September and October this recurred, and at the latter date she had ergot. About the beginning of November she returned to town, and soon after she aborted. The aborted mass corresponded very closely in appearance to that figured on page [illegible] of Playfair's "Science and Practice" as illustrative of [illegible] apoplexy. In Dr. Wallace's case there was no hi[illegible] syphilis. The lady had had five living and he[illegible]ren, but between the third and fourth there wa[illegible] of an abortion. In June the patient had rov[illegible]nally, which was an unaccustomed exercise for [illegible]ater on in the autumn she had a serious shock to her ne[illegible]ous system on the occasion of the Crarae Quarry disaster. Dr. SLOAN thought the presence of a brownish discharge occurring during pregnancy invariably indicated the fact of a clot having been thrown out between the utero-ovarian surfaces, and being in process of decompositon.

Puerperal Eclampsia.—Dr. MALCOLM BLACK read a paper on Puerperal Eclampsia, recording an experience of thirty-nine cases, of which four had occurred in his own private practice and the rest in the practice of the Maternity Hospital or otherwise. He said the proportional mortality was reckoned by Lusk as 1 in 500 cases, and by Churchill 1 in 600 cases, of confinement. He went deeply into the etiology, pathology, and treatment of eclampsia, and the paper was listened to with great attention, and followed by an interesting debate, in which nearly all the members present joined.

HOSPITAL SATURDAY FUND.—At a meeting of the board of delegates of this fund held on the 18th inst., the awards for the present year were agreed to. The following are the principal amounts:—Brompton, £589; London, £586; Victoria-park (Chest), £288; Middlesex, £276; St. George's, £267; St. Mary's, £224; Metropolitan Convalescent Home, £211; Westminster, £208; University College Hospital, £204; North London, £176; King's College, £175; Royal London [illegible]hoo, £168; Charing-cross, £162;

Reviews and Notices of Books.

Diseases of Tropical Climates. By WILLIAM CAMPBELL MACLEAN, C.B., formerly Professor of Military Medicine to the Army Medical School, Netley.

THERE can be no doubt of the want of a treatise, brought down to date, on the subject of diseases of tropical climates, and there can be no question that the person to whom all would look for such a work would be the Netley Professor of Military Medicine.

In his introductory lecture Surgeon-General Maclean recalls most forcibly the immense saving of both human life and public money which has been achieved by the sanitary labours of the Imperial Medical Service, and while exhorting all to continue these efforts the lecturer adds a word of judicious warning to young surgeons, that when making suggestions to those "who have the responsibility of military command on their shoulders," they should not do so bumptiously, but rather modestly, and points out that memoranda not written as becomes "an educated gentleman" will fail to command attention. It is with some disappointment that on turning to the lectures on the vexed subject of cholera we find certain passages which show Dr. Maclean to be a little wanting in that toleration which he so wisely inculcates.

The author's views on the cause of the spread of the disease we find formulated in propositions lettered from *a* to *n*, which, when condensed, are as follows:—*a*. Bryden's endemic area of cholera is true, but not the only one. *b*. The force which gives epidemic energy is unknown. *c*. The south-west monsoon is the indirect cause of the dissemination of cholera, especially because it is before this wind that the large fleet of country boats moves up the Ganges—cholera thus spreading no faster than man moves. *d*. Cholera when raging in Burmah has never been carried to the Andamans. It can travel as fast against the wind as with it. *e*. The infective property of cholera is in the stools which have undergone change. *f*. These stools convey disease through drinking-water. *g*. Dried cholera stools may be carried by the wind and infect through the lungs. *h*. Food polluted with cholera stools induces the disease. *i*. Clothing soiled with the same may communicate it. [illegible] of men may carry and propagate disease. *k*. A hea[illegible]ment meeting and communicating with an infect[illegible] certainly be affected. *l*. A regiment entering [illegible] district will almost certainly be infected. *m*. If [illegible] a used cholera camp it will certainly be infect[illegible] outbreak on board ship will be found coincident with the opening up of some infected cargo.

In support of these conclusions Dr. Maclean offers the three following instances narrated by independent observers In the first, "a small quantity of fresh cholera stool was mixed with five gallons of water, and exposed to the sun for twelve hours. Nineteen persons partook of an ounce each; within thirty-six hours five of these had cholera." Again, "an epidemic in fifteen days carried off more than 100 of the high caste population, who drank only from two wells which were reserved in the centre of the village for their use, while not a single person of low caste whose drinking-water had to be procured elsewhere died; a street only separating the two castes, and in some places their abodes were continuous." Lastly, an account is given of a number of native prisoners who had been lately employed near the Moolah river being attacked with cholera; only those who drank below a certain dam were affected. Cholera prevailed a little at the time, and two cholera corpses had been washed below the dam."

While agreeing with Dr. Mac[illegible] that th[illegible] of evidence at present [illegible] of the operation, its movements [illegible] retention of [illegible] conium to escape. The wounded parts [illegible] themselves

chief means by which the disease spreads, we at the same time consider that his position as the instructor of those upon whom the future investigation of the source of cholera must devolve rendered it more than ever imperative that he should have also pointed out the arguments which favour the opposing view: for instance, the significance of the negative fact that fourteen persons swallowed with perfect impunity exactly the same dose of the same mixture which proved fatal to the other five, and the complicating factor that all were living within the choleraic field of an existing epidemic. Again, in the second instance the propinquity, and in some cases the continuity, of the abodes of the affected and unaffected would, while strengthening the contention in favour of its diffusion by drinking water, exemplify most strikingly the mysterious nature of the disease, which would appear at times to decline all other means of propagation. For the refutation of the "locomotive power" of wind in cholera epidemics Dr. Maclean relies apparently on proposition *d*, at the same time forgetting that, as a bimonthly mail, frequent trading steamers, and a large fleet of cargo boats keep up incessant communication between Burmah and the Andamans, his proposition (*e*) [illegible] boat-carriage is equally cancelled. Such easy disposal of the theory of wind locomotion is scarcely in keeping with the suitable tribute paid in his introductory lecture by Dr. Maclean to Dr. Bryden, "an officer of whom it is not too much to say that he was one of the ablest vital statists the medical profession has ever produced."

To the earnest seeker after truth there can be no such thing as hostile opinion, since every conclusion honestly arrived at by another should, by putting restraint on too hasty generalisation, prove a welcome assistance. We therefore regret the omission of all reference to the researches of Drs. Klein and Gibbes into the water-supply of the villages in the neighbourhood of Calcutta, and that from first to last there is no allusion whatever to the labours of the Cholera Commission, which published its report more than a year ago; and this is the more unaccountable as three of the author's colleagues formed part of that Commission. As it now stands, the young surgeons on probation may, as far as they can learn from the perusal of this work, remain in ignorance that such a Commission ever sat.

Passing to the excellent lectures on Malaria and the diseases produced thereby, we find that Dr. Maclean, while unable to entertain the proposition of cholera being "earth-born and air-borne," defines malaria as an "earth-born poison, for the most part generated in soils the energies of which are not expended in the growth and sustenance of healthy vegetation." This is scarcely less indefinite than the "certain electrical conditions" of Surgeon-General Munro, which the author summarily rejects. The directions for treatment will be of great use to young surgeons commencing practice in a foreign climate. One suggestion with reference to the use of quinine we miss—viz., the marked effect attainable by the hourly administration of even one grain for eight or ten doses. This was first pointed out by the medical officers who were in such straits during the Mauritius epidemic to economise the drug.

The lecture on Enteric Fever we can unhesitatingly commend to the careful study of every medical officer. It is clear and liberal, and points out the value of the "filth factor" in the production of the disease, while at the same time recounting the cases which occurred in South Africa and in the Soudan, in which the poison appeared to have been either autogenetic in the individual, or to have arisen *de novo* in the locality. In the directions given for the treatment of dysentery, the dose of tincture of opium (fifteen minims) with which it is proposed to prepare the stomach for retaining the half-drachm of ipecacuanha [illegible] appears to be rather small; at least double that quantity [illegible] been found advantageous. The rules laid down for the

diagnosis and treatment of bot... ...estion and suppurative inflammation of the liver ...ove very helpful to the beginner, and we entirely co... with Dr. Maclean in his desire that the words "hepatitis, acute and chronic," should cease to form a cloak for slovenly diagnosis.

We regret that so many paragraphs of the lectures on malarious fevers, insolatio, and diseases of the liver should be devoted to warnings against antiphlogistic methods of a bygone period, and that Dr. Maclean should have thereby subjected himself to his own very apt criticism of "pulpit exercise, putting up a man of straw for the satisfaction of knocking him down again." We are also jealous of the space given to various extracts from writers whose labours we must always venerate, but whose teachings are not at least of the discoveries of to-day. At the same time it is but fair to note that Dr. Maclean says that the regulation "that all lectures delivered here should be submitted to the Secretary of State for War, has acted as a check on him, as he cannot publish under a censorship."

We have long held that the young surgeons sent to Netley are the only State-aided men of science in the department of biology in the empire, and we are accordingly of opinion that it is incumbent on them, wherever their executive duties permit, to avail themselves of the opportunities of travel to seek the explanations of many obscure influences which materially affect life. Such a course produced a Darwin. But at the same time these young surgeons have every reason to expect that at Netley they shall be brought up to the latest date in the most recent advances of every science which bears upon their special calling. We would even venture to think that, as the professors of this school have the last word with the departing investigators, they might, having laid a solid basis for military medical practice, be a little bold with the theory, and, on the principle that "even a false theory, instead of hindering, hastens the advance of knowledge," might, like Professor Aitken at page 77, project their ideas into regions where the scientific use of the imagination may be their chief guide. A little more robustness in the Netley teaching would not depreciate its value.

OUR LIBRARY TABLE.

Clinical Manual for the Study of Medical Cases. Edited by JAMES FINLAYSON, M.D. Second Edition. London: Smith, Elder, and Co. The appearance of a new edition of this very complete guide to clinical investigation is significant of the increased attention that is being paid to practical study and ward work. The volume before us has the merit of being contributed to by several physicians, and is consequently thorough in its treatment of the various subjects. The editor is responsible for the main bulk the sections on case-taking and on the symptomatology of disorders of the various systems; but Dr. Alexander Robertson contributes the chapter on Insanity, Dr. Joseph Coats that on Examination of the Fauces, Larynx, and Nose, Dr. W. Stephenson that on Disorders of the Female Organs, and Dr. Sampson Gemmell that on the Physical Examination of the Chest and Abdomen; whilst Dr. Gairdner introduces the volume with an interesting essay on the Physiognomy of Disease. The student could hardly wish for better guides, and the manner in which the subjects are dealt with proves the high standard of excellence in clinical teaching at Glasgow. In this new edition there have been several additions to the text, and many fresh illustrations have been introduced. A commendable feature is the bibliography appended to each section.

Knight's Manual relating to Dairies, Cowsheds, and Milkshops. London: Knight and Co.—In this manual all the provisions of the law and of the Orders of the Privy Council and Local Government Board which relate to the sanitary condition of dairies, cowsheds, and milkshops are collected and explained; and as the change that has been made by the Act of last session has had the effect of making sanitary authorities throughout the kingdom the bodies to administer the law as now altered, the local officials who are concerned in the work will be in need of such guidance as is here supplied. The supervision of dairies, cowsheds, and milkshops is a matter of no slight importance to a community like our own; and although the requirements of the Order issued by the Privy Council in 1885 are, from a sanitary point of view, by no means as complete as could be desired, one is able, with the assistance of the well-edited edition of the Order, which is comprised in this manual, to see exactly how far the application of any provision extends. Some useful hints are given as to the regulations that may be made by sanitary authorities under the Order; and a set of model clauses, which, it is stated, have been prepared with great care so as to meet all the requirements of the Local Government Board, as well as those of local authorities, is added for the guidance of such authorities. The book is throughout replete with useful and instructive notes in explanation of the requirements of the statutory provisions and the Orders. In one case, "dangerous infectious disorder" is stated to have been interpreted to mean "cholera, diphtheria, erysipelas, measles, scarlatina, small-pox, typhoid or enteric fever, and typhus fever," and the importance of such an explanation as this cannot be denied, for it so frequently happens that dairymen and others are under the impression that the regulations prohibiting infected persons from being concerned in the distribution or storage of milk apply only to some specially virulent forms of disease. In another note the important fact is brought out that the terms of the Order of 1885 are not sufficiently wide to prohibit the milk of cows suffering from disease during a milk-scarlatinal epidemic such as that which recently occurred in Hendon and London from being sold or used for human food, although such a prohibition exists where the animal is suffering from cattle-plague, contagious pleuro-pneumonia, or foot-and-mouth disease. Other instances might be given of the helpful character of the notes that are plentifully scattered throughout the book; but enough has been said to show that the work is likely to be extremely useful, and may be accepted as containing ... ive information which will be really helpful to all w... ncerned in the administration of the Act and O... which it deals.

... über die Diagnostik der Gehirnkrankheiten. Von ... WERS, M.D., F.R.C.P. —This is a German translation of the author's work on the Diagnosis of Diseases of the Brain. The translator, Dr. J. Mommsen, appears to us and to the medical press of Germany to have accomplished his task in a satisfactory manner. The demand that exists on the Continent and in America for Dr. Gowers' books proves his claim, should he care to establish it, to the title and designation of a successful and distinguished medical author of European and American reputation. Dr. Gowers' books are read in the English, French, German, and Russian tongues, and his other contributions to medical science are eagerly translated into the language of every country that can boast an acquaintance with the arts and sciences of the civilised world.

Leitfaden zum Gebrauch des Augenspiegels für Studente und Aerzte. Von Dr. ADOLF VOSSIUS. Mit 22 Holzschnitten. Berlin, 1886. Pamphlet. Pp. 78.—This is a short introduction to the use of the ophthalmoscope, and contains the substance of the author's lectures to his class. Thus he describes the nature and action of lenses, the refractive constants of the eye, the blackness of the pupil, the mode of illuminating the fundus, the appearances presented by ... astigmatism, and so on. Two ... diseases of the choroid

and retina. The accounts given are good as far as they go, but are, of course, very brief—mere diagnosis, in fact.

On Heat considered as the Retinal Intermediate of Light and Colour Sensation. By L. WEBSTER FOX and GEORGE GOULD. Pamphlet. Pp. 23.—The authors accept Wundt's theory that light and colour sensations are modifications of a photochemical process, but propose to substitute the term thermal for that of photochemical; and they endeavour to show, with some success, that the conditions present are favourable to the preservation of heat and the conversion of light into heat.

Whitaker's Almanack, 1887.—This Almanack has this year been entirely recast and very greatly enlarged, extending now to no less than 632 closely printed pages. All its usual contents have undergone complete revision, much has been amplified and enlarged, and many fresh subjects of great public interest have been incorporated. Amongst the special articles are—an Analysis of the Irish Government and Land Bills; the Merchant Marine; the Navy as compared with the Naval Forces of Europe; and Annals of Her Majesty's Reign. The Almanack contains a greater amount of general information than it has ever done in past years, and is beyond question the best publication of the sort with which we are acquainted.

Diaries, &c.—We have received several specimens of these useful publications.—Messrs. C. Letts and Co., 3, Royal Exchange, have forwarded us copies of their improved *Office Diary* and *Note-book, Continuous Diaries*, and *Rough Diary*. These books are all well got up, some of them being interleaved with blotting-paper, and fully maintain the standard of excellence reached by this firm in past years. *Pettit's Shilling Folio Scribbling Diary* will be found useful to those who desire to obtain at a trifling expense a volume for the record of their engagements and occupations during 1887.—*Blackwood's Diary* is published in an extremely convenient form and contains maps of some of the principal cities of Great Britain, together with information respecting cab fares, postal arrangements in various parts of the country, &c.—*Family Records* is intended to be what its name implies—viz., a record of all that is most notable: birthdays, marriage days, and death days, removals, agreements, engagements, &c., occurring in a family during a generation. It is published by Houlston and Sons, Paternoster-square, and will, without doubt, deserve ... mand success.

RUPTURE OF THE URINARY ...

To the Editor of THE LANCET.

SIR,—Whilst cordially congratulating Sir William Mac Cormac on an operative success, the importance of which can scarcely be over-estimated, I shall be obliged if you will allow me to make some remarks arising out of his references to my article in "Heath's Surgical Dictionary." 1. The remark quoted by Sir William was not, as he puts it, that "no indubitable case of recovery after intra-peritoneal rupture of the bladder is on record," but "no indubitable case of *spontaneous* recovery." The omission of the word *spontaneous* might make me chargeable with the rejection of Dr. Walter's case of successful abdominal section ten hours after the injury without suture of the rent in the bladder. I am not prepared for this. 2. Sir William says, "As regards the interval after the injury at which the operation may be successfully undertaken, this may possibly prove greater than has hitherto been held. Mr. Rivington speaks of some period within the first twenty-four hours. In one of my cases twenty-six hours had elapsed." I did not say that an operation could not be successfully undertaken after the first twenty-four hours. My words were, "abdominal section ought to ... performed ... within the first twenty-four hours to ... observation w... ...tly, perhaps, on Dr. Walter's case, but main... ...incent's experiments on dogs, which resulted ... ...ant failure from urinary intoxication when perfor... ...twenty-four or twenty-five hours after the bladder was wounded. My object was to lay stress on the extreme value of early interference, in order to make sure of success. I sincerely trust that it will be found that the human peritoneum absorbs less rapidly than the canine, and that an operation done, say, within the first forty-eight hours may prove more often successful than the reverse, but I think that the prognosis becomes less favourable with every hour of delay. 3. Sir William says, "In ordinary traumatic cases of intra-peritoneal rupture of the bladder, the margins of the rent are generally lacerated in appearance, and soon become swollen. Mr. Rivington recommends paring these edges off, but when they are fully inverted by the method of suture, paring becomes unnecessary, and needlessly adds to the difficulty and duration of the operation." My words were: "Prevention of further accumulation and transmission of urine into the peritoneal sac in the male may be secured by sewing up the rent in the bladder with carbolised silk sutures, *with or without paring the edges of the ragged rent*. If this procedure be adopted, the bladder should be injected with water before the abdominal wound is closed, to make sure that leakage is not possible." It will be seen that I recommended not paring the edges as much as I recommended ...ing them. The fact is, that I was really uncertain which procedure absolutely to *recommend*. In my monograph on "Rupture of the Urinary Bladder" I rather leaned to the idea of not suturing the rent at all, owing to the lacerated and contused condition of the edges and to Walter's successful case. In the Dictionary, I had in my mind, when I used the expression "with or without paring the edges," either the adoption of Vincent's method of suture, or what is called with regard to the intestine the Lembert method adopted by Sir William Mac Cormac—a method which would not involve paring, or else the adoption of paring to remove all spoiled tissue not likely to unite by first intention, followed by accurate adjustment of the edges of the opening. Experience had been so limited, and authorities so widely differed, that I added in the monograph: "Whether the rent in the bladder should be sewn up or not with or without paring the edges must be left to be determined by future experience"; and in the article "further experience is required to test the value of *all operative measures*." Owing to the very limited space at my disposal for my article in the Dictionary, I omitted the description of Vincent's method given in the monograph. These remarks will show that I did not write in that spirit of dogmatism which, however necessary it may be for instructing children, patients, and students, is in scientific matters unendurable, and, like the haughty spirit, often precedes a fall. Sir William Mac Cormac's fortunate experience must be taken as the guide in future operations, and proves the following points:—1. The advantage of operating as early as possible. 2. The advantage of thoroughly cleansing the peritoneal cavity by means of a mild antiseptic solution. 3. The superiority of carbolised silk to catgut for suturing the rent in the bladder. 4. The reliability and value of Vincent's *sero-muscular* (but *not serous*) sutures. 5. The reliability of the catheter as a means of removing urine from the bladder after *efficient* suturing of the rent in the bladder. My belief is that Sir William Mac Cormac's success is the prelude to similar success, not only in cases of rupture of the bladder, but in cases of ruptured intestine, and even of ruptured stomach. Dr. Blundell, who certainly preceded his American namesake in proposing to suture a ruptured bladder (see THE LANCET, Feb. 21st, 1829, p. 646) mentions (*in loco*) that "Mr. Travers, so well known by his excellent writings, has tied up with success a small aperture in the stomach." Celerity of operation would be absolutely essential in a case of ruptured stomach, and even more necessary in cases of ruptured intestine than in cases of ruptured bladder. Under these circumstances, I wish to suggest that house-surgeons should be instructed to take in and watch carefully all patients who had been subjected to such violence applied to the abdomen as would suffice to rupture one of the hollow viscera, whether exhibiting any immediate symptoms or not. It not unfrequently happens that cases of ruptured bowel and bladder are allowed to go home because at the outset the patients do not appear to have been seriously injured.—I am, Sir, yours, &c.,

Finsbury-square, Dec. 18th, 1886. WALTER RIVINGTON.

THE LANCET.

LONDON: SATURDAY, DECEMBER 25, 1886.

THE ANNUS MEDICUS 1886.

THE year 1886 will be remembered amongst us rather for medico-political changes than for any striking advances in medical science, though the record which follows will show that there is no halting in the march of the medical art. Medical practice has been less arduous, and probably less profitable than usual. The prevailing depression has doubtless led the public to regard medical care more as a luxury and less as a necessity; and disease itself, owing to the moderation of the seasons and the development of sanitation, has been less prevalent and virulent. But we anticipate our history.

Physiology.

In the wide domain of biology, the Germans have shown themselves extraordinarily active, and the attention of numerous observers has been directed to the comparatively new subject of bacteriology. The best works that have been published are those of FLÜGGE, "Die Mikro-organismen," which deals with microbes both in their histological and their hygienic relation, and is remarkably complete; CORNIL and BABES' "Les Bacteries," which is likewise very perfect, and is beautifully illustrated; and KLEIN'S admirable little work on Micro-organisms. Other important works on the same subject are those of HUEPPE, entitled "The Methods of Investigation in Bacteriology," of MITTENZWEIG on the "Relations of Bacteria to Infectious Diseases," and of HUBER and BECKER on the "Pathological Relations of Bacteria"; whilst a year-book upon the "Advances in our Knowledge of Pathogenic Micro-organisms, including Bacteria, Fungi, and Protozoa," has been written by Dr. P. BAUMGARTEN, and forms a volume of very respectable size. Several of these works give photographic representations of the objects described in the text, and those who are interested in such methods of illustration may read with advantage Dr. COWLEY MALLEY'S little work on "Photomicrography," which includes a description of the wet collodion and gelatino-bromide processes, with the best methods of mounting and preparing microscopic objects for photomicrography. The works that have appeared on General Physiology have been few, and have consisted chiefly in the publication of new editions of well-known treatises: such as those of LANDOIS, translated by STIRLING, which is certainly one of the best works on physiology hitherto written; and GRUENHAGEN'S edition of the WAGNER-FUNKE'S Physiology, a standard German work. Dr. FERRIER has published a new and valuable treatise on the "Functions of the Brain," being a second edition of his well-known work. Dr. DALLINGER, in his presidential address, delivered before the Royal Microscopical Society, took occasion to describe in detail the chief results he had obtained in a long series of researches, showing the great importance of the nucleus in the process of fission amongst the lower organisms, and in the more complex process of generation of new cells and animals. Many separate memoirs of more or less importance have, however, of course appeared. LANGLEY and EDKINS have shown that pepsinogen precedes the formation of pepsin in the glands of the stomach, and that the change of the former into the latter probably takes place only during digestion, and under the influence of acids. Quantitative researches on the constituents of the bile in infants by JACUBOWITSCH, show that, notwithstanding the large relative size of the liver in them, the proportion of bile secreted is less than in adults, and there is a remarkable absence of glycocholic acid in the bile of infants under one year old. DRECHSEL has isolated a peculiar azotised and sulphur-holding organic substance, which is contained in the liver of young animals, to which he has applied the term "jecorin," the composition of which is highly complex. SCHOTTEN believes that human bile contains a special biliary acid, which he names Anthropocholalic. MINKOWSKI extirpated the liver or ligatured the afferent vessels of the gland in many birds, and found that the quantity of urine increased, whilst the excretion of nitrogen by this channel fell to one-half or two-thirds its previous amount; the elimination of uric acid was greatly diminished, whilst that of ammonia was correspondingly increased. CHITTENDEN and LAMBERT adduce evidence to show that the sugar found in the liver after death is derived from proteids rather than from glycogen. The difficulties attendant upon the study of the dynamics of the circulation are considerable, and there are many points on which our knowledge is defective. An attempt to supply some of these deficiencies will be found in a paper published in MICHAEL FOSTER'S *Journal of Physiology*, by S. DE JAGER of Utrecht, which is well deserving of careful study. Nothing can show better the very uncertain foundations on which some of the most generally received opinions in physiology rest than the fact that within the last month two memoirs have appeared on the physiology of the respiratory movements which are strongly opposed to each other. One is by MAX MARCKWALD, who admits the existence of two centres of respiration, one for inspiration and one for expiration, which is excited with greater difficulty, for expiration. These are situated in the medulla oblongata, but as a rule the inspiratory centre alone acts. He shows, in opposition to the generally received theories, that the stimulus to respiration is not either a deficiency of oxygen nor an excess of carbon dioxide in the blood, since animals are capable of breathing for a long time without circulation of any blood at all. He thinks the real stimulus may be the products of the disintegration of the intercellular juices. WERTHEIMER, on the other hand, thinks there are no special centres beyond the vagal nucleus in the medulla oblongata, but that there are special centres in the spinal cord, and the stimulus he believes to act on the peripheric extremities of the vagus, and to consist essentially of changes in the gases of the blood. A very long and carefully written article on the mode of termination of motor nerves has just been published by KÜHNE in the *Zeitschrift für Biologie*, in which he describes the results he has obtained in a long series of preparations made from all classes of vertebrata. The end plates are fully described and shown to be beneath the sarcolemma of the muscular fibres. The illustrative drawings are very numerous. The [illegible] has long been a [illegible] histologists, and

various opinions have been propounded in regard to it: amongst others, suggestions have been made that it represents an eye formerly existing in saurians, and still existing in a rudimentary state in some reptiles. The subject has been carefully worked out in various lacertilia by W. BALDWIN SPENCER, who has brought forward much evidence in support of this view, and shows that the pineal eye was highly developed in ichthyosaurus and plesiosaurus, and may be regarded as peculiarly a sense organ of pre-tertiary periods. HORSLEY and SCHÄFER, from their investigations on muscles in contraction, have arrived at the conclusion that every prolonged contraction of the skeletal muscles which is provoked by excitation, whether natural or not, of any part of the nerve centres is a tetanic contraction which has been produced by a series of impulses generated in the nerve centres and passing along the motor nerves at an average rate of about ten per second. An excellent article has been published by W. H. GASKELL on the structure, distribution, and function of the nerves which innervate the visceral and vascular systems, which should be studied by every working physician, since it adds much to our knowledge on this difficult and obscure subject. Observations made by STEPANOW upon a case of aural disease, in which about the upper turn and a half of the cochlea were destroyed, has satisfied him that no positive statements can at present be made in regard to the functions of particular parts of the cochlea, since no defect in the perception of high and of low notes existed.

Pathology.

The most notable, or at least the most widely known, contribution to the pathology of the year is unquestionably the research of PASTEUR and his pupils into the nature of hydrophobia, and the practice of protective inoculation based on that research. The correctness of his experiments and the value of his discovery have been vouched for by independent observers, including a commission sent to Paris from this country in the spring; but, notwithsta... this, there still remains a degree of scepticism whic... to be met before the practice can be considered ...ed. A significant silence has been maintained o... ...t in Berlin, where we naturally look for confirma... ...ts of this class; whilst the very abundance of cases which have been treated by PASTEUR has rather obscured than elucidated the main issue, owing to the uncertainty of the bites inflicted being really those of rabid animals. Still, as has been justly remarked, if in only one case PASTEUR has succeeded in neutralising the effect of the virus, his method must be claimed as a real gain to our powers of prophylaxis. In connexion with this subject of rabies, it may be noted that Dr. DOWDESWELL announced in these columns the discovery of a microbe peculiar to the affection, which hitherto has evaded observation; but we are not aware that this discovery has been as yet confirmed. The transmission of disease to human beings through the medium of infected milk has received fresh and striking illustration in the investigations of Drs. POWER and KLEIN upon an epidemic of scarlatina traceable to milk and to the cows yielding it. The results of that inquiry point to a primary infection of the mil... ...d therefore to an actual transmission of this ...

cognate subject ...mission of tuberculosis by diseased milk has ...g the past year received fresh substantiation. Ba... ...logy continues to be widely studied, and the extent to which it is pursued may be gathered from the fact that in Germany special journals have been started to be devoted solely to records of researches in this field. In this country owing mainly to the writings of WATSON CHEYNE, KLEIN, CROOKSHANK, and others, the methods of investigation pursued, and the characteristics of septic and pathogenic microbes have been made widely known; whilst the New Sydenham Society has done good service in publishing translations of many of the most important memoirs on the subject that have appeared on the Continent of late years. It would not be possible within the limits of a summary such as this to attempt anything like a detailed review of the advances made in bacteriology. Mr. WATSON CHEYNE has written on this subject in the pages of the *International Review of Medical Sciences*, to which we may refer our readers. But we may mention that the interesting subject of actinomycosis has been studied anew by Dr. T. ACLAND and others, and that the bacterium of pneumonia — the so-called pneumonococcus — has received a large share of attention; one interesting fact being its discovery in cerebro-spinal meningitis by FRÄNKEL, and another the differentiation of varieties of microbe by WEICHSELBAUM in the several kinds of pneumonia. Dr. DOWNES has continued his researches upon the influence of sunlight on micro-organisms; and Dr. PERCY FRANKLAND has studied the subject of the prevalence of bacteria in air and water, following up the well-known observations of MIQUEL. An important contribution to the etiology of endocarditis has been made by WYSSKOWITCH and ORTH, who were enabled to produce the disease experimentally by introducing streptococci into the circulation of animals whose valves had been injured. Fresh contributions to the subject of choleraic microbes have been made by Dr. CUNNINGHAM and Dr. KLEIN, the former to a certain extent retracting his previous opinions respecting the comma bacillus; but the past year has not, on the whole, produced much in the way of either confirming or disproving the alleged specificity of this microbe. The subject of ptomaines and leucomaines has been exhaustively treated by GAUTIER, and discussed at length in the French Academy. Early in the year CANTANI announced the successful treatment of phthisis by the bacterium termo, but not many months elapsed before this notion, wholly based on theoretical grounds of the antagonism between the tubercle bacillus and the putrefactive bacterium, was completely upset. Indeed, therapeutics have not yet been able to successfully keep up with the increase of knowledge upon the nature of many diseases. In the death of Surgeon-Major LEWIS we have lost one of the most painstaking investigators in bacterial pathology, whilst the English school of pathology has lost in Dr. MOXON one of its most brilliant and original exponents. The subject of evolution in pathology was ably treated by Mr. BLAND SUTTON in lectures delivered before the Royal College of Surgeons, based upon his investigations upon disease in animals. Dr. AITKEN also, dealing with the subject of evolution from another point of view, illustrated the relationship between febrile diseases. Prof. VIRCHOW,

again, has discussed the [illegible]othesis in its bearings on pathology, especially [illegible]t to the transmission of acquired defects by in[illegible]ce. The Pathological Society of London has continued to do good work, the most notable feature of its past session being the exhibition of specimens of intra-cranial tumours by numerous members of the Society, and, amongst other contributions to the year's work, may be cited Mr. LANE'S observations upon the causation of rheumatoid arthritis, and Dr. PAYNE'S paper on granuloma fungoides.

Therapeutics.

There has been activity in every department of therapeutics during the past year. Hygienic, prophylactic, surgical and medical therapeutics have been agitated by the introduction of new methods, principles, and details. PASTEUR'S prophylactic must occupy the first place, though some will claim for it a pathological rather than a therapeutical position. Brain surgery has had some remarkable developments, and no [illegible] remarkable successes witness the work of HORSLEY, HULKE, BARKER, MACEWEN, and others. The surgical treatment of empyema has been illustrated by Mr. RICKMAN GODLEE'S lectures at Brompton, and by a new method of treatment by *perflation* by Dr. EWART. The appearance of two more volumes of Dr. VON ZIEMSSEN'S "Cyclopædia of General Therapeutics" must be welcomed as attempts to place on a firmer basis the rational treatment of disease by artificial, climatological, and balneological methods. In the literary field we have had also a new edition of Dr. RINGER'S work; a new volume on "Materia Medica and Therapeutics" by Dr. C. D. F. PHILLIPS; new editions of "Waring's Therapeutics" by Dr. DUDLEY BUXTON, and of MITCHELL BRUCE; a small book by Mr. A. W. GERRARD; besides numerous pamphlets dealing with special diseases. Our columns show that the treatment of whooping-cough has occupied considerable attention. Cardiac tonics have received much practical consideration from Dr. JAMES BARR and Dr. SANSOM; in this department we may perhaps note a permanent and highly useful acquisition in the form of some preparations of strophanthus and strophanthine, which appear to be valuable in place of digitalis, and chiefly because the blood-pressure is not raised by the contraction of the arterioles. But it is too soon yet to decide as to the final outcome of this innovation. We believe that convallaria and convallamarine have not maintained their positions in the race with digitalis, which still holds the chief position (see the articles by Dr. SANSOM and our leading article on cardiac tonics). Cocaine continues to hold an important place in therapeutics, and has been used in almost every region of the body. It is not too much to say that this wide extension in its application has not been unwarranted. In acute pharyngitis, in prostatitis, in vaginal affections, sea-sickness, nasal and other neuralgiæ, in cancer of the uterus, nymphomania, and in many diseases of the eyes (as we remark in another column), its use has been attended with good results. We have heard something also of the toxic effects of cocaine, but some of these may have been due to peculiarities in the patient or disease for which the drug was administered, and perhaps sometimes to impurity of the drug. By some lanoline will be considered as the greatest addition of the year, and there can be no doubt of its value, especially in its higher penetrating property, as compared with other ointment bases. Naphthaline is a valuable internal antiseptic agent for certain cases of cystitis and intestinal disorders; ulcers have been treated by external application with excellent results. For the relief of pain and for counter-irritation solidified liniments of menthol and other articles have been freely employed, and appear to have found favour with patients and practitioners. Antifebrin and antipyrin are new antipyretic agents; the latter has been in use for a few years but the former is a recent acquisition, and is said to be four times as powerful as the latter. Acetophenone and urethane are additions to our means for combating insomnia. Hypnotism, with suggestion during the hypnotic state, has been advocated as a curious method of treatment (see p. 1157). Intubation of the larynx in diphtheria does not seem to have found many advocates in this country. Peritoneoclysis, hypodermoclysis, and vesicoclysis formed the subject of a communication by Dr. MACDOWALL on the treatment of cholera. Dr. CHEADLE contributed some valuable articles on the treatment of constipation in childhood and infancy. Of salicylates we have had salicylate of lithia as a substitute for the soda salt in rheumatism, though it does not appear to have been much employed. Salicylate of bismuth would appear to possess some advantages over the trisnitrate in some gastro-enteric affections. Salol is another salicylate in which one atom of hydrogen in the salicin has been replaced by the monovalent phenol group; it has antipyretic and antiseptic properties, and has been freely used on the Continent as a substitute for the soda salicylate. In the treatment of phthisis attention has been drawn to the value of inhalations by the mouth and gaseous medication by the rectum. The inhalation of hydrofluoric acid has been said to effect much benefit. The rectal medication comes from France, but has been tried also at the Victoria Park Chest Hospital, though with what results we are unable [illegible] present to say. The principle of the treatment con[illegible]e introduction into the system of sulphuretted hy[illegible] with carbonic acid (see THE LANCET, p. 638). Ter[illegible]nally and externally, has been tried in chro[illegible]s and many other diseases of the chest, at th[illegible]n of Dr. MURRELL. In some cases it does a grea[illegible] of good, but by no means in all. Other derivatives of turpentine have also been freely used, especially terpine on the Continent. Pyridin has been prescribed freely in asthma. Calomel as a diuretic has formed the subject of several communications to our pages. Viburnum prunifolium has been extolled for the prevention of abortion. The insufflation of iodoform into the trachea after tracheotomy has been favourably alluded to. Mr. TWEEDY has written on the mydriatic properties of hydrobromate of hyoscine. Electricity has been praised by Dr. STRAVENSON and Mr. BRUCE CLARKE in the treatment of stricture of the urethra, in cystitis, and in sciatica. The publication of Dr. MURRELL'S book on "Massage as a Mode of Treatment" was made the occasion for the free expression of opinion on the differences between ordinary medical rubbing, shampooing, pétrissage, and effleurage.

Of disquisitions on foods and feeding we have had abundance. Sir [illegible]M Ro[illegible] book of Lectures on Dietetics [illegible]book, and numerous

letters on infant feeding, with two leading articles in our columns, have formed the staple of this important department of therapeutics.

In the pharmaceutical region our progress has been uninterrupted. The various artificial foods, peptones, glutens, and the like, have further increased the resources of the practical physician. And there seems to be no end to the number of improvements in the art of manufacturing "elegant" preparations.

Surgery.

The introduction of what we know as the "antiseptic method" of treating wounds has revolutionised surgery in more senses than one. Previous to that time the treatment of wounds could not be said to be the subject of greatest interest and of paramount importance with all surgeons, and it was difficult to excite enthusiasm in a discussion as to the relative merits of poultices, ointments, lotions, and dry dressings. But to-day it is impossible to attempt any survey of the progress of surgical practice without at once speaking of the changes which are passing or have passed over what is now the universally received practice antiseptic surgery. In reviewing the year's work, it is only fitting to chronicle at least two important changes the abolition of the spray, and the substitution of simpler dressings for the old carbolised gauze. It is now some time since "*fort mit dem Spray*" formed the text for an able lecture which sent a thrill of horror through the more pious followers of Sir JOSEPH LISTER. To-day it is an accomplished fact, and there is now quiet and comfort where formerly hiss, bubble, and spurt, and wet irritating clouds made an operating theatre almost as terrible to surgeons as to patients. We are well aware that the spray is still extensively used by some operators, or for certain operations by others, but as a general adjunct to wound treatment it has distinctly, and we believe finally, fallen from the high position it once held. And this not because it has been found to be useless or harmful, as such, but because it has been replaced by the safer, more handy, and more pleasant irrigation of [illegible] in conjunction with this change we are witnessing the substitution of corrosive sublimate for carbolic acid, which have elucidated the antiseptic agent. For many years the original gauze has had serious rivals in salicylic and iodoform wool, and in thymol and eucalyptus gauze, but now it has given way to a very large extent indeed replaced by salaleno-broth wool and gauze, although iodoform wool is still much used. Have these changes been attended with benefit? We believe that a distinct affirmative must be given to this question, and that there is a widespread feeling that the disuse of the spray and the substitution for it of corrosive sublimate irrigation has not only rendered the practice of antiseptic surgery simpler and pleasanter, but safer and more successful.

It would be impossible to refer here to every detail of surgical progress that has been chronicled in the year that is now closing, and we must content ourselves with mentioning some of the more prominent facts. In the front rank must be placed the increased and highly satisfactory results obtained in the department of cerebral surgery. Tumours of the brain have been successfully removed, traumatic epilepsy has been cured [illegible] due to ear [illegible] successfully brought within the dominion [illegible] operating surgeon. Large sections of the skull [illegible] been removed with a freedom that recalls the practice so ruthlessly condemned by JOHN BELL. There is nothing special to chronicle in regard to pulmonary or thoracic surgery, and the completeness and success with which almost all abdominal affections have been submitted to operative treatment have left little room for improvement. Renal surgery has fully maintained its satisfactory position, and we can now speak of hepatic surgery. Incision and drainage of the gall-bladder, removal of biliary calculi, and drainage of cysts of the liver are all of them recognised and largely successful procedures. The most important facts in reference to the surgery of the bladder are two: that supra-pubic cystotomy has been frequently practised for the removal of tumours of the bladder, and that lithotomy has been successfully practised upon boys for whom previously lithotomy would have been held to have been clearly indicated. Supra-pubic lithotomy has gained in favour in comparison with the perineal operation, and its greater safety is generally recognised. We must also direct attention to two cases of ruptured bladder which were recently successfully treated by suture by Sir W. MACCORMAC. A revival of the old and discarded practice of the electrolytic treatment of stricture of the urethra must be mentioned. We need not venture on a prophecy of what this will effect, but some of those whose experience dates back for twenty years or more, to a time when electrolysis was as much lauded as now, are ill inclined to receive without question all the claims made for this revived method of treatment. Faith in its virtues has not been increased by some of the remarkable statements made as to the very speedy good effects of electricity upon chronic affections of the bladder. In the surgery of the limbs, it is to be noted that excisions of diseased joints are more and more unpopular, and that they are to a large extent superseded by the operation of erasion, which in suitable cases has given most excellent results. Our record of the year's advance would be very incomplete were we not to mention the growing popularity of cocaine as a local anæsthetic. The injection of one or two drops of a strong solution secures complete local anæsthesia, and permits of the painless removal of superficial tumours or of other slight operations, such as circumcision.

Such are the main points of interest in connexion with the surgery of 1886. The position now held by the surgeon's art is a very high and enviable one, and we may confidently anticipate that if at the end of next year we have to mention modifications of existing modes of practice, they will be improvements and developments as well. There never were so many good surgeons as there are to-day, and the combination which can now be often seen of manipulative skill, wide and varied experience, and scientific habit of mind is the surest guarantee of the future progress of surgery.

Obstetric Medicine.

In this department some excellent work has been done in the course of the year, and we would mention the following papers:—Dr. HERMAN on the production of the Shape of the Oblique Pelvis of Naegele; Dr. MATTHEWS DUNCAN on Contraction, Inhibition and Expansion of the Uterus, and on Elasticity, Retraction, and Polarity of the Uterus; Dr. JOHN

PHILLIPS on Spurious Hemapl... ...HAN DORAN on Malformations of the Fallopian ... CHAMPNEYS on the Uterine Bruit; Dr. DAKIN on Me... ...ism in Lying-in Women after Injection with Sublimate Solution; Dr. BERRY HART on the Nature and Causes of the ...ovement of Internal Rotation; Dr. MILNE MURRAY on some of the Physiological and Therapeutical effects of Wa... at Different Temperatures, with special reference to Obstetric and Gynecological Practice; and Dr. HALLIDAY CROOM on the Etiology of Hæmaturia. Dr. BARBOUR opened an interesting discussion before the Edinburgh Obstetrical Society on Micro-organisms in their relation to Puerperal Fever, with special reference to Antiseptics. The operation of "tapping" has been much discussed; the report of the Committee appointed by the Liverpool Medical Institute to inquire into the frequency of the performance of this operation at the Liverpool Hospital for Women may, however, conduce to the formation of accurate views on the subject.

Ophthalmology.

In ophthalmic surgery the use of cocaine in various operations upon the conjunctiva as, for example, in peritomy and the opening of tarsal tumours has become general. It is also almost universally employed in the operation for the extraction of the lens in cataract, and manifestly with the greatest possible advantage to the patient. It does away with the serious effects accompanying the use of chloroform, avoids the distressing and dangerous sickness so often attendant upon the use of that agent, permits the patient to fortify himself with a little food before the operation, and enables the operator to proceed leisurely and to extract the lens without iridectomy, thus preserving a round and active pupil. With fresh and pure solutions, in strength not exceeding 4 or 6 per cent., which are quite sufficient to produce complete anæsthesia, no ill effects have been observed from its use. A very good paper on cocaine and its action on the pupil was read before the Royal Society (and has been published in its proceedings) by Mr. JESSOP. The useful plan of setting aside a special evening for the consideration of some one important disease, and of collecting from many quarters facts and opinions in regard to such disease, has been followed out with advantage by the Ophthalmological Society, whose handsome volume of Transactions for the present year opens with a memoir on the obscure affection known as Graves' disease, which contains the histories, more or less complete, of a large number of cases. The Transactions contain also a memoir of equal importance on sympathetic ophthalmitis, which is based on the accounts by various observers of no less than 200 cases, and which affords many hints for treatment in this serious affection. Other interesting subjects which occupied evenings of this Society were meningitis after excision of the eyeball (brought forward by Mr. NETTLESHIP); and the irrigation operation for cataract (by Dr. M'KEOWN), which consists in washing away the cortical substance so often remaining after extraction with pure water—the objection to which seems to be the danger, unless the instruments are exceedingly carefully kept and sterilised, of ...troducing foreign bodies into the eye and setting up inflammation of an unhealthy character; and a case recorded by WICHERKIEWICZ, in which a solution of carbolic acid was inadvertently injected, though it did not prove fatal to vision, shows that great care requires to be exercised. The treatment of ulcers and infectious abscesses of the cornea by lightly touching the affected surface with the actual cautery has been strongly recommended by NIEDEN, who reports that he has had 88 per cent. of successes, with the trifling drawback of a cicatrix, which did not, however, interfere with vision. The existence of a special bacillus in syphilis, constituting the active agent in various syphilitic affections advanced by various microscopists, and especially by LUSTGARTEN, has been contested by ALVAREZ, who, in a communication made to GALEZOWSKI's *Recueil d'Ophthalmologie*, maintains that the supposed bacilli of syphilis are identical with those found in the smegma præputii. One of the most valuable works hitherto published on the hygiene of the eyes—that, namely, by HERMANN COHN—has just been translated by Mr. W. P. TURNBULL, and well deserves to be in the hands of every schoolmaster and pupil teacher. COHN advocates the institution of a special class of experts, to be called "school doctors," whose function should consist in regulating the hours of work, the length of the holidays, the structure, heating, ventilation, and lighting of all school buildings, the construction of desks and forms, the treatment of epidemics, and various other duties. There can be no doubt that such an officer is urgently needed in English schools, for at present not one of the defects mentioned by Professor COHN receives attention in any of our public schools; and if boys do not suffer seriously, it is rather because in England the hours of work are, in comparison with those of France and Germany, considerably fewer in number, and are intermingled with much more relaxation. Lastly, we may call attention to the excellent treatise on the Accommodation and Refraction of the Eye by LANDOLT, which is undoubtedly the best that has appeared on this subject since that by DONDERS, published by the Sydenham Society twenty years ago.

Royal College of Physicians.

T... ...mare which the College of Physicians is now tak... ...ty of examining candidates for the licence to ... ...considerably increased the work annually trav... ... its walls. The meetings of its Fellows a... ...pied with matters of much wider interest t... ...d questions of considerable moment come up... ...gment. As we write, the highly important ma... ...ical degrees being granted by the conjoined Colleges under consideration, the resolution to take action in the matter having been passed fifteen months ago by a large majority. Before the close of another year we may, then, see this question solved in a manner which, without in any way trenching upon the cherished privileges of the College, will show that it is in earnest in furthering the cause of medical education in London. The erection of the new Examination Hall by the two Colleges, and the Royal ceremonial that inaugurated the work, render the past year a memorable one in their history, and it seems probable that a further extension of the work of the Colleges will follow upon their acquisition of the land adjoining this building. The College of Physicians has also during the past year been engaged ... considering the clauses of the ... been to cement the

bond of union with the sister College. Another result of this Act was the application from the Apothecaries' Society to join the Conjoint Board. This application, which the Act required the Society to make before it could take any further steps to get its diploma recognised as a full legal qualification, was declined by the Colleges on the ground that their examinations, as at present framed, provided a complete qualification. Opinions differ both as to the wisdom of that reply and as to the effect it will have upon the Apothecaries' Society, as well as upon the profession at large; but this is not the place to discuss these controversial questions. Passing to the internal affairs of the College, it may be noted that certain proposals for delegating the duties of the Comitia to standing committees, brought forward by Dr. WEST, were rejected. The Croonian Trust Fund having been greatly augmented, the scope of its foundation has been enlarged, and made to include the appointment of lecturers on subjects of anatomy, physiology, and pathology, and the prosecution of scientific investigations on these subjects. By the bequest of the late Dr. GAVIN MILROY, the College became possessed of a sum of money to found a lectureship in State Medicine. Nor should mention be omitted of the fact that this year Sir W. JENNER was elected President for the sixth time—a mark of confidence which the profession at large heartily endorsed. The Harveian Oration was delivered by Dr. PAVY; the Bradshawe Lecture by Dr. DRESCHFELD, who chose for his address the subject of Diabetic Coma. The Lumleian Lectures by Dr. STONE dealt with the somewhat recondite subject of the Electrical Conditions of the Human Body. The Croonian Lectures were given by Dr. LATHAM, on some Points in the Pathology of Rheumatism; and the Gulstonian Lectures by Dr. SHARKEY dealt ably with the subject of Spasm in Chronic Nerve Disease.

Royal College of Surgeons.

Probably at no other period of its existence has the Royal College of Surgeons been so active as during the past year. Whether we understand the term "College" in the Council or the whole body corporate, the events of the past will be memorable in its annals. The changes which have been introduced into between this College and the Royal College of Physicians is significant of the times, and of a tendency, which the policy of the latter College especially has shown, to lower their licence included both medicine and surgery, and thus qualified for general practice, as well as for Post-graduate other appointments. The gain is therefore largely on one-sided one. On the other hand, a much larger number of candidates will henceforth seek the combined diploma, and so equalise matters. Moreover, the union effected will strengthen both Colleges, and can hardly fail to raise the status both of licences and of licensees. The two Colleges decided to build an Examination Hall suitable for the increased numbers of candidates which are expected; accordingly plans were prepared for a building capable of accommodating not less than 600 candidates at one time. After being approved by the joint committee of the two Colleges, and also by the Duchy of Lancaster, on whose freehold the hall is being built, the foundation stone was laid with great pomp by Major [illegible] on March 24th. It is hoped that the building will be ready early in the new year. Acting in accordance with the recommendation of the Committee of Delegates of the two Colleges, the Council of the College of Surgeons have practically accepted the principle that it is desirable that degrees in medicine be conferred on candidates who have passed the conjoint examinations. The event, perhaps, of next greatest interest and importance that has occurred during the past year is the coming into possession by the College of money bequeathed by the late Sir ERASMUS WILSON—upwards of a quarter of a million sterling. We say "coming into possession": in reality, we believe, the College has no right to hold so much money, and will have to acquire that right by new charter. The importance of this wealth can hardly be over-estimated. If appropriately used, the College of Surgeons will be able to promote the science and study of surgery in a manner never before attempted in this country. The question of internal reform, however, is the one which has attracted most attention during the past year, and which has been urged on the Council with great force, with great persistency, and with equal moderation. To judge by the circular recently issued to the Fellows at large with a view to elicit their opinion on the two prominent questions of reform, we fear the Council, notwithstanding some show of concession, are as resolutely opposed to any change as when the agitation first began some years ago, and the Members themselves will probably have to petition Her Majesty for a new Charter and for a restitution of those privileges of membership which have gradually been withdrawn from them. How this has been done is briefly set forth in some articles we published on Oct. 30th and Dec. 11th, and in a letter of the latter date from an esteemed correspondent, "Historicus." A study of these articles is urged on every Member of the College. Here he will learn how the present College began, how it was originally constituted, the purposes it had to serve, and how the *status quo* (which deprives Members of all voice in College management) is a flagrant breach of the fundamental principle of corporation. The annual meeting of the Fellows and Members was largely attended, and some important resolutions, jointly agreed upon by the two Associations of Fellows and of Members respectively, were brought forward, discussed with great ability, and carried. These resolutions, demanding on behalf of Members of the College of a certain standing corporate rights, were practically a reiteration of similar demands which have been previously urged on the Council at different times. An important feature at this meeting was the great unanimity of both the Fellows and Members on the question of reform. Mr. TIMOTHY HOLMES, formerly a member of the Council, acted as the mouthpiece of the two Associations. And here the matter rests for the present.

Army, Navy, and Indian Medical Services.

The past year has not been marked by any important change in these branches of the public service. The supply of candidates has been such as to indicate that they are still considered desirable outlets for the young men who are joining the profession. There are, however, some matters deserving the careful consideration of the authorities if they wish to maintain this feeling. The first of these is the removal of the just ground of complaint on the part of the

surgeons on probation for the [illegible]missions are dated from the conclusion of th[illegible]ruction at Netley, while those for the Indian ser[illegible] the date of their joining there. This is so obviously [illegible]t that we hope it is only necesary to bring it under the notice [illegible]e Secretary of State for War to have it rectified. [illegible] this is done we fear the existing practice will serio[illegible]ffect the supply of candidates for that branch. Another [illegible]ter which calls loudly for redress is the position of bri[illegible]-surgeons in India, for although nominally recognised, they are denied the advantages of pay and allowances which ought in justice to attach to the rank. The position of medical officers in India, and the duties they are all called upon to perform, have been so modified by the introduction of the station hospital system in lieu of the regimental, that the whole question of their pay and allowances appears to require revision, and we trust that it may meet with early attention on the part of the authorities. There is still another point which merits the consideration of the Secretary of State for War—the s[illegible]m of conferring rewards and honours upon medical officers. The present system, by which the recommendation for rewards is almost exclusively in the hands of the military officers, while the head of the medical department is practically ignored in the selection, and his recommendations, when he thinks fit to make any, are too often set aside, is most unsatisfactory. We have so recently brought to notice this want of recognition of meritorious professional services that we think it unnecessary to say more than that we sincerely hope we may be able in our 'Annus Medicus for 1887" to announce that some more equitable system has been adopted, and that professional merit will no longer be left unnoticed and unrewarded in the medical branches of the public service.

The Medical Council.

The Medical Council met twice in the course of the year 1886. First on Tuesday, June 1st. The session lasted till Thursday, June 10th inclusive. The principal occupation of the Council during this sitting was the discussion of the reports of the visitors of all the Universities, or rather of their final examinations for medical degrees. These visitations cost the sum of £2256 9*s.* 2*d.*, or about twice as much as the visitations of corporations. The criticisms of University examinations were fairly faithful and satisfactory. The unsatisfactory part of it was that by the terms of the instructions given them the Visitors were restricted to ascertaining that the examinations were a test of mere *competence* to practise, instead of being required to see whether University examinations as such were fixed at a higher standard than those of corporations. The Council at the June meeting also resolved to institute a visitation of medical *schools*, subject to the permission of schools. The Council again met, very inconveniently, on Tuesday, November 16th, in the middle of the election of direct representatives under the new Medical Act, of which we shall have immediately to speak. They sat for five days. At this meeting little of importance was done, save to purge the Registers of two or three names. The only motion of any consequence discussed was one by Dr. MCVAIL, seconded by Dr. BANKS of Liverpool, to extend the term of medical education by one year, or rather to make five years compul[illegible] the subjects of Elementary Physics, Chemistry, and Biology are to be included in the period of medical study. An almost identical resolution had been passed the previous year, but had not been carried out. The Chairman put this resolution in a somewhat technical way, in supposed imitation of the forms of the House of Commons. The Council got into a terrible fog from which it never clearly emerged, though the resolution was declared carried by 10 to 3.

This may be considered a convenient place for noticing the passing of a Medical Bill to be known as the Medical Act, 1886. This Bill passed through its final stages in June. It is noticeable that, though the Medical Council sat in the middle of the progress of the measure through Parliament, it took no action in the matter. There was, indeed, on its part and on that of the medical authorities, a sort of conspiracy of silence to let it pass, no doubt in the belief that it affected their individual interests less than any measure could be expected to do. The silence of the Medical Council was the more questionable as it was contrary to its practice in regard to similar Bills, and the Bill, as the President of the Council has since pointed out has left the great reform unaccomplished—viz., a consolidation of the licensing authorities. It remains to be seen whether we shall not have a greater development than ever of competition of the licensing bodies, though under somewhat altered and veiled forms Another reason why the Medical Council should have been more concerned to give its opinion on the Bill than on former occasions is to be found in the free way in which the Privy Council is required to co-operate with the Council, and in some cases to override its decisions. We were the sole objectors to this feature of the Bill, and have to acknowledge the courtesy and consideration of the Government in the matter. Under the Act one good point has been gained—the admission of direct representatives of the profession to the Council. As the Bill was originally drawn by Sir LYON PLAYFAIR, two representatives were given to England, and one res[illegible]ely to Ireland and Scotland. By the hearty efforts [illegible]ALTER FOSTER a third representative for Engla[illegible]ined, Sir LYON graciously giving up one of th[illegible] for the purpose. There is one other good [illegible] Bill. It requires that the Medical Cou[illegible]nt inspectors of the examinations. Thi[illegible]y be hoped, will secure, at little more cost [illegible] present system of visitations, a more regu[illegible]atic report of the methods and work of our e[illegible]horities than we have hitherto had. A serious [illegible] the new Medical Act is the provision for registerin[illegible]oreign and colonial degrees under certain important conditions. Under this Act the first election of Direct Representatives took place in November. The event is so recent that we need not trouble our readers with the particulars further than to record that after an election conducted on the whole quietly and in good humour, the following gentlemen were declared to be duly elected—viz.:

For England:
Mr. CLAUDIUS GALEN WHEELHOUSE, F.R.C.S.Eng., Leeds.
Sir B. WALTER FOSTER, M.D., F.R.C.P.L., Birmingham.
JAMES GREY GLOVER, M.D. Edin., London.
For Scotland: WILLIAM BRUCE, M.D. Edin., Dingwall.
For Ireland: Dr. GEORGE [illegible]IDD, F.R.C.S.I.

[illegible] Act in the work of

our Legislature to record, if we except the repeal of the Contagious Diseases Act on the motion of Mr. STANSFELD.

The Medical Societies.

There have not been any striking changes in the work of the Medical Societies during the year now ending. Everyone regards the regular clinical meetings of the London Medical Society as far more interesting than the mere reading of papers, and this method of bringing members together is one to be recommended even more extensively. The interest is greater when living specimens of disease can be examined in a profession where the oldest is not too old to learn, and it is certain that practical demonstrations are more truly instructive than any amount of language, however graphic. We have only space enough to indicate the chief contributions that have been communicated to the various Societies, London and provincial:—The Lettsomian Lectures on Some Moot Points in the Natural History of Syphilis, by Mr. JONATHAN HUTCHINSON, F.R.S. Diseases of Bones and Joints in Animals, by Mr. BLAND SUTTON. Spontaneous Fracture of Urinary Calculi, by Mr. S. G. SHATTOCK. Diffuse Sclerosis of Brain in an Infant, by Dr. ASHBY. The Surgery of the Suakim Expedition, by Mr. TOBIN, at the Academy of Medicine in Ireland. Mortality in the Medical Profession, by Dr. WILLIAM OGLE. Dr. OGLE showed the excessive Mortality of Medical Men from Epidemic Diseases, excepting Small-pox, from which they have the sense to protect themselves; also from Gout, Diseases of the Liver Urinary Diseases, &c. (an abstract of this paper will be found in THE LANCET of Jan. 30th). Intracranial Tumours, by various authors, at the Pathological Society. Papers on Pemphigus (?) of the Conjunctiva, by Dr. BRAILEY and Mr. LANG Mr. NETTLESHIP'S paper on Meningitis after Excision of the Eyeball. Dr. HERMAN'S communication to the Obstetrical Society on the Production of the Shape of the Oblique Pelvis of NAEGELE. Subperiosteal Resection for Acute Necrosis, by Mr. BERNARD PITTS. Enteric Fever at Sue[illegible] to [illegible]ed. Dr. J. E. SQUIRE. Mr. ARTHUR BENSON'S pape[illegible]ish Academy on Embolism of Retina an[illegible]t in [illegible] Dr. TYSON'S cases of Universal Alopecia [illegible]ts of [illegible]gical Society. Dr. HALE WHITE'S paper on "H[illegible] which have [illegible]ia. Dr. ROBERT MAGUIRE'S communication [illegible]elucid[illegible]ter[illegible] Re[illegible] [illegible]oduc[illegible]pool, af[illegible] the Thumb-joints. Dr. CAYLEY'S on [illegible]t has [illegible]een [illegible]m treated by the Introduction of Steel W[illegible]broth wool [illegible]c. A paper on Ovarian Displacements at the [illegible]rsed. [illegible]by, by Dr. MORE MADDEN. Mr. B. POLL[illegible]ely [illegible]ance of Villous Tumour of the Accessory Thyroid [illegible]Mr. SHATTOCK'S paper on Bilateral Cystic Disease of the Kidneys in the New-born. Papers on Aneurysm at the Clinical Society, by Mr. MANSELL MOULLIN and Mr. CHARTERS SYMONDS. Dr. GOODHART'S case of Intussusception of the upper part of the Jejunum. Mr. BARKER'S case of Acute Intestinal Obstruction treated successfully by Abdominal Section. Dr. PERCY KIDD'S specimen of Diffused Symmetrical Cirrhosis of the Lungs. Dr. MACLAREN'S case of Hernia Cerebri treated by Silver Plate closing the Opening in the Skull. Drs. WHIPHAM and MYERS' paper on the Nervous Sequelæ of Small-pox. The report of a committee of the Ophthalmological Socie[illegible] Ophthalmi[illegible] Dr. BRISTOWE'S c[illegible] Optic Ne[illegible]g MOORE WILLIAMS and Mr. R. J. GODLEE'S pa[illegible]lo-phlebectasis treated by Paracentesis. Mr. PEARCE G[illegible]which case of Alveolar Abscess with Thrombosis of the [illegible]avernous Sinus. Papers and discussion at the Royal Me[illegible]t and Chirurgical Society on Suprapubic Lithotomy, by [illegible]andi[illegible]ARWELL, Mr. JACOBSON, Mr. W. RIVINGTON, and Sir H. [illegible]verPSON. Tubercular Ulceration of the Palate, by Mr. CLU[illegible]at h[illegible], and also by Dr. ABERCROMBIE and Dr. GAY. Mr. MEREDITH'S paper on Successful Laparotomy for the relief of Acute Intestinal Obstruction following Ovariotomy. Dr. STEPHEN MACKENZIE'S paper on Erythema Nodosum and Rheumatism. Dr. MATTHEWS DUNCAN'S paper on Contraction, Inhibition, and Expansion of the Uterus. Dr. CLIFFORD ALLBUTT'S suggestive paper on the Mountain Case in Heart Disease at the Leeds and West Riding Society. Dr. CHAMPNEYS' paper on the Development of Mammary Functions of the Skin of Lying-in Women. Dr. F. W. MOTT'S specimen of Malignant Melanotic Growth of the Lip. Mr. BALLANCE and Mr. W. EDMUNDS' most valuable paper on the Ligature of Larger Arteries in their Continuity. The various communications on Exophthalmic Goitre to the Ophthalmological Society. Many papers on Adenoma of the Palate, by Mr. HUTCHINSON, Mr. STEPHEN PAGET, and Mr. F. TREVES. Dr. A. MONEY'S paper on Delirium and Fever in Pneumonia. Mr. BRUCE CLARKE and Dr. STEAVENSON'S paper on Electrical Treatment of Urethral Stricture. Dr. ZEHENDER'S Bowman Lecture. Dr. HAMILTON'S Complete Sections of Brain. Mr. F. TREVES' specimens of Malignant Cysts of the Neck. Mr. KNOWSLEY THORNTON'S paper on 300 Complete Cases of Ovariotomy. Mr. CHARTERS SYMONDS' case of Removal of Scapula for Osteo-sarcoma. Dr. COUPLAND'S paper on Ophthalmoplegia dependent on Thrombosis of Cavernous Sinuses. Dr. SHERRINGTON'S specimens of the Ascending Antero-lateral Tract in the Embryo. Dr. BARLOW'S case of Disseminated Mycelitis and Measles. Dr. A. H. N. LEWERS' paper on Spontaneous Uterine Rupture. Dr. SEMON'S, Mr. BUTLIN'S, and Mr. MORRIS'S papers on Extirpation of the Larynx for Epithelioma. Dr. HUGHLINGS JACKSON'S rare case of Epilepsy like that of epilepsy in guinea-pigs. The Obstetrics of the Kyphotic Pelvis, by Dr. CHAMPNEYS. Dr. DRESCHFELD'S and Dr. PAYNE'S papers on Rhinoscleroma and Granuloma Fungoides. Mr. LANGTON and Mr. BOWLBY'S paper on Embolic Aneurysms. Mr. HERBERT ALLINGHAM'S new method of Excision or Erasion of Knee-joint. Dr. CROOKSHANK'S specimens of Flagellated Organisms in the Blood of Healthy and Diseased Rats.

Medical Associations.

The meeting of the British Medical Association at Brighton was, in a medical respect, a great success. The attendance was good, and many of the addresses were of great interest. That of the President, Dr. WITHERS MOORE, was devoted to a consideration of the function of women, especially as regards Higher Education and Professional Pursuits. Dr. MOORE developed with great ability the argument that the great function of woman was to be the mother of good men, and that any departure from this line of duty was to be regarded with regret and doubt. His views supplied material for discussion of this great question for many days. Sir [illegible]K'S Address on Cases in which

Disease of the Valves of the H[eart] ...xist for upwards of five years without ... was a masterly and compact statement of ... clinical experience, and very comforting to peop... ...hearts. Other addresses of consequence were those ... ...LINGS on the state of Medical Education in the ... States, and of State Law as it affects Medicine as a ... and a Profession, Sir HENRY THOMPSON on Supra-... Litho-tomy, Dr. BARNES on the Alternatives of ... ...otomy, Dr. JULIUS DRESCHFELD on Pathology, Dr. R... on Peripheral Neuritis, Dr. LAUDER BRUNTON on Therapeutics, &c. With a view to the approaching election of Direct Representatives under the Medical Act, a proposal was made, at a general meeting, to instruct the Council to select three names of gentlemen and submit them to a future general meeting during the session. Dr. EYTON JONES, Dr. HUGH KER, Dr. DOLAN, Mr. MORRIS, Dr. BERNARD O'CONNOR, and others spoke; and finally it was agreed that the Association, as such, should take no action in the matter.

The Sanitary Institute of Great Britain met at York, and had the advantage of being presided over by Sir SPENCER T. WELLS, who, like most great surgeons, is much interested in the principles of sanitation, and has done much to enforce and apply them. In his address Sir SPENCER took a broad and statesmanlike view of the subject. He lamented the impotence of Parliament and its preoccupation with less practical and more sensational topics; but he descanted with much satisfaction on what had been achieved in the improvement of the people and the lengthening of the average of human life by almost twenty years in the last half century.

The proceedings of the Meeting of German Naturalists and Medical Men in Berlin were reported in abstract in our columns in October. At such meetings in Germany there is much more specialism and a greater number of sections than in England. Professor VIRCHOW, in an introductory address, alluded to the close connexion between the natural sciences and medicine, and observed that this connexion was much more recognised in Germany than with us.

Medical Jurisprudence.

The year that is just passing away has been signalised by one medico-legal case of surpassing interest. We refer to the charge brought against Mrs. BARTLETT and the Rev. GEORGE DYSON for the murder of Mr. BARTLETT by administering a fatal dose of liquid chloroform. The Crown prosecution withdrew the indictment drawn against Mr. DYSON, and the jury found Mrs. BARTLETT "Not guilty." There could be no doubt that deceased succumbed to the effects of liquid chloroform taken into the stomach, but it remains a mystery how this came about. In a leading article on the forensic bearings of the case we directed attention to the difficulty of surreptitiously giving chloroform vapour to a sleeping person, and we took exception to the theory that the cause of death from swallowing pure chloroform was mainly irritation of the stomach, contending that the shock from the irritant would be minimised by the stupor from the narcotic. Several other interesting cases of poison—and some of them curious and rare—have been recorded in our pages. ... woman named HUNT succumbed to the lethal effects ...rus, but the jury were unable to determine how ...s administered. The motive appeared to arise from the fact that she was *enceinte*, but whether this worked through a suicidal or homicidal groove has not been ascertained. Perhaps the most curious—and curious mainly because it was equivocal—instance of supposed poisoning was that which occurred at Hackney, and was investigated toxicologically by Dr. TIDY. This jurist obtained an extract from the contents of the stomach like that derived from KEATING'S insect destroyer; the powder in question, however, failed in a three-ounce dose to kill a rabbit. At Clerkenwell a man was poisoned by carbonic anhydride whilst working in a disused well; and at about the same time a calamitous event happened near Glasgow, several persons losing their lives by the after-damp succeeding a huge explosion. Wild flowers of undetermined nature proved fatal to a child. A suspicious case of poisoning by wood sorrel was explained by us as probably due to the drinking of soap lees. Just recently a child aged two years and a half died in convulsions after eating sixty grains of camphor.

Turning now from the account of poisons, we must mention briefly the circumstances of a trial for murder, in which W. TURNBULL, a medical man, and MARY NOTTAGE, a certificated midwife, were charged with having procured abortion on a single woman named CLIFFORD. The prisoners were convicted of "unskilful treatment and criminal negligence," and were sentenced respectively to ten years' penal servitude and eighteen months' hard labour. The post-mortem phenomena observed in this and a similar case formed the basis of an article by us on the value of the corpus luteum as a sign of previous pregnancy.

A distressing case of death from rupture of the uterus during labour was brought to light at an inquest at Brighouse. The midwife in attendance was supposed to have acted injudiciously in making traction on a leg in a breech presentation, and so inadvertently causing the rupture. The evidence failed, however, to sustain the suspicion, and the jury returned an open verdict as to how the uterus was rent.

At a ...trial on the civil side, a dentist was sued for d... the seduction and consequent impregnation ... during the sleep of the latter. The jury ... took occasion to point out that unco... ...tion was consistent with physiological law...

A ...ue of post-mortem examinations, num... ...ve presented themselves to illustrate and ...peated contention that in all cases where ... is doubtful a necropsy should be made. Mr. ...EPHEN laid stress on the desirability—nay, necessity—of this being done whenever the death was the subject of a criminal charge. On one occasion a juryman, much to his credit and to the furtherance of justice, declined to sign an inquest form unless he heard medical evidence as to the cause of death. At Hull an inquiry into a supposed case of "irritant poisoning" was completed by the post-mortem examination revealing peritonitis from acute inflammation of the ovary.

"Impulsive homicide" has again elicited public and professional notice, notably by reason of two trials which occurred at the late Western Assizes. These were rendered ... more ... by ...nimadversions passed by

Mr. Justice HUDDLESTON on medical witnesses—strictures which we felt compelled to challenge and resent.

A curious case of mistaken identity transpired at an inquest, where the subject of inquiry, though sworn to as dead, appeared in person to prove the contrary. The deceased and his counterfeit both had a peculiarity of the same finger of the same hand.

Public Health.

On the whole, the year 1886 has been a healthy one in so far as England and Wales are concerned, and there is every reason to believe that the general death-rate will indicate a distinct diminution as compared with the average for the preceding ten years. The decrease in the rate from the zymotic class of diseases was very marked during the first half of the year, and it was only an excessive prevalence of fatal diarrhœa during the third quarter that brought that rate at all near to the previous average. During that quarter the mean temperature was 1·5° above the average for the corresponding periods of 115 years, the largest excess occurring in September; the rainfall was also 2·46 inches below the average amounts in the corresponding periods of seventy-one years; and these are conditions with which excess of diarrhœa amongst infants has always shown itself in those localities with which the prevalence of this fatal malady is identified. The total diarrhœa deaths were 15,936 in number, corresponding with an annual rate of 2·27 per 1000, as opposed to a mean rate of 1·84 in the ten preceding third quarters; the highest local rates reaching 5·36 in Salford, 5·49 in Preston, 6·23 in Leicester, and 8·24 in Norwich. The study of this disease, especially as regards its etiology, is still being carried on by Dr. BALLARD on behalf of the Local Government Board, but since the principal opportunities for study are of such short duration and at such long intervals, some time must probably elapse before any definite views on the subject can be formulated. But, quite apart from this autumnal diarrhœa, we are from time to time learning of specially localised epidemics which appear to be due to use of certain articles of food and drink. Wat... ied. ...n the means of producing the most widely ...t in these epidemics, and the latest record we ... ts of subject relates to an epidemic which sudd... which have some 20,000 of the inhabitants of Hull ... elucidated ... the epidemic being associated with a te... pol... ital pollution of the public water-servi... ...e of these epidemics indicates more than ... broth... ol ...tive necessity of placing all such servic... ...ised, ... and skilled supervision. Small-pox, fev... ...ever all show diminished death-rates, and, exce... so far as the change may be affected by an improved diagnosis and differentiation between scarlet fever and diphtheria, it is satisfactory to observe that a steady diminution has for some time past been in progress in the deaths from the former of these two diseases. Diphtheria, on the contrary, has shown a tendency to increase, and the increase has for some years past exceeded anything that can be accounted for by reason of improved nomenclature. So far, however, although there is no diminution in the diphtheria fatality, the increase that has heretofore been in progress has not been further added to this ye...

The recurrence of ... ...s

natu... ...ct ... ...ming of the attention of the Local Gover... ...s ... ...g of the local sanitary authorities; and the ... ...vey of districts running special risk, whether ... which ... of their position on the coast line or by reason ... ...vn or suspected sanitary defects, has been of extreme ... ...ce. The Local Government Board, having selected ... ...d of their most experienced medical inspectors for the ... ...ise, have by local counsel and correspondence indicated ... ...at by several hundred sanitary districts where the weak points existed which could favour a cholera spread, and we have reason to believe that the interference and personal advice which have been such prominent features in this survey have, in by far the majority of instances, been appreciated by local sanitary bodies. The issue ... Dr. BUCHANAN'S recent cholera report showed that some authorities preferred a mistaken economy to the improvement of the health of their districts. With them must be left the responsibility of failing to secure for their inhabitants the sanitary conditions best calculated to prevent the spread of disease. Such bodies will, at least, be una... ...o complain ...hat they were not made acquainted with the principles which govern the action taken in this country for the prevention of cholera, and which relate essentially to the removal of filth in all its forms and to the provision of means of isolation for those who are actually sick.

From time to time we have indicated the course of cholera in Europe during the present year. The fact of the disease being maintained during a portion of last winter in certain parts of Spain and in the north of France did not lead to any further extension of the disease in those two countries, both of which had suffered severely in 1884 and 1885. Italy was less fortunate. Throughout the early part of this year the disease was more or less prevalent in Venetia. It gradually extended to the provinces bordering on and to the south of the mouths of the Po, and it ultimately extended over a wide area in the north-eastern portion of the peninsula. Whilst this extension was in progress the disease appeared at Brindisi and Bari in the south, and from these places it spread to a large number of towns and villages near the Adriatic coast, and to others inland. The total number of attacks and deaths in Italy has not yet been officially certified, but from the commencement of the renewed epidemic early in the year to the end of September, when a considerable fatality was still in progress, the persons attacked had probably not been less than 50,000 in number, and amongst them there had since been some 15,000 deaths. When cholera was first prevalent in the neighbourhood of Venice, it spread inland and also extended to Trieste, the disease being maintained at the latter port and in its vicinity throughout the greater portion of the year. The whole province of Istria soon became infected, and extension of the disease took place in the direction of Croatia. Later on it became evident that villages in the southern part of Hungary were affected; then Pesth (the eastern portion of the capital) became for a time the seat of the epidemic; and at a still later date Galicia to the north and certain towns and villages to the south of Hungary became implicated. At the ... date rumours are renewed as to the existence of ... several parts of Eastern Europe, and in all ... ...t danger for the coming year will ...

The large amount of attention ... year devoted to perfecting our sanitary co... f the possible extension of cholera to this ... e to diminish the amount of current work in ... ation of epidemic disease at home. But, even ... ear's labours had been limited to a single piec... k, we should still be able to regard it as marking ... in our sanitary history in view of the proof that h... st been afforded as to the relation of a disease in the ... o scarlet fever in the human subject. Mr. POWER'S ... orts to the Local Government Board have at several intervals foreshadowed the possibility of the existence of such a relation, and his recent admirable piece of work, as embodied in his report and that of Dr. KLEIN on Milk Scarlatina in London, must be regarded as affording the proof hitherto needed, and as opening up a comparatively new and wide field for further scientific investigation. The sanitary legislation of the year has been but small in amount, and the only Act to which it is necessary to draw attention is the Contagious Diseases (...mals) Act, 1886, which definitely transfers powers as to dairies, milkshops, &c., to the sanitary authorities, who heretofore had no proper means of controlling establishments which may become potent for mischief as regards the public health.

Hospital Mirror.

In the Mirror of Hospital Practice during the past year cases from most of the departments of medical practice have been brought forward—many of them interesting from the rarity of the disease, and some on account of an unusual manifestation of symptoms or rare complication obscuring the diagnosis and rendering it difficult for the carrying out of skilled and successful treatment. Amongst others may be mentioned the following:—A fatal case of hydrophobia, hyperpyrexia in the course of acute rheumatism, enteric fever fatal on the seventieth day from perforation, unusual symptoms in connexion with locomotor ataxy, chorea associated with epilepsy, chorea gravidarum, tropical and other abscesses of the liver, and a series of cases of pyæmia. Contributions to toxicology include recovery after poisoning by oxalic acid (half an ounce), followed by acute nephritis, hydrochloric acid (one and a half ounce), liquid chloroform (two ounces), cyanide of potassium (40 grains), and one by phosphorus paste, fatal on the fifteenth day; also an account of the sufferers from the effects of the gases following the disastrous explosion at Crarae. Injuries to the skull and its contents have been several times brought before our readers, and the advantages of the present methods of treatment exemplified by the success which has attended the efforts of the surgeon; bullet wounds and compound fractures of the vault, with in some cases damage to the brain, requiring the use of the trephine or elevator; fractures of the base associated with multiple fractures of the bones of the face and others, as also a fatal case of trephining for traumatic epilepsy; and two cases of tetanus successfully treated, one by the excision of cicatrix, the other by chloral hydrate. Functional disease of the heart, aortic regurgitation, ulcerative endocarditis; several examples of aneurysm, with the ligature of arteries, the femorals, common iliac, and two cases of simultaneous ligature of the common carotid ar... ...rysmatic aneurysm of the gluteal; hæmorrhage from post-scarlatinal ulceration; and a case of hæmophilia, with the pedigree for five generations. In connexion with the digestive system: excision of the whole of the tongue for epithelioma, and of portions for tubercular ulceration; perforating ulcer of the duodenum; intestinal obstruction from fæcal accumulation; stricture of the rectum, simple and malignant (in one case simple stricture caused a complete block for two months); volvulus and acute intussusception, with the treatment in each. Examples of the treatment of the principal varieties of strangulated hernia by the improved method of excision of the sac, often combined with suture of the ring after reduction of the gut; also cases in which hernia was simulated by other diseases. Œsophagotomy for the removal of a tooth-plate; gastrostomy for malignant stricture of the œsophagus; the formation of an artificial anus where new growth obstructed the rectum, either by LITTRÉ'S or AMUSSAT'S operation; and the exploration of the gall-bladder for stone (when unusual conditions were found and the gall-bladder was removed); and this week we publish notes of a rare case of fatal general emphysema, due to perforation of the wall of the œsophagus. Accounts will be found illustrating the treatment of diseases of the generative organs in the female; operations for the removal of cyst, of the ovaries and broad ligaments, of hydro- and pyo-salpinx and myo-fibromata of the uterus; hydramnios; pregnancy complicated by occluded vagina, by albuminuria, and by chorea and successful operation for extra-uterine fœtation. The revival of the operation of supra-pubic cystotomy has led to increased activity in the treatment of vesical disease, and cases are recorded of its employment in children for the removal of stone, and in the adult (with perineal incision) for the removal of tumour from the bladder. Other methods for removal of calculi and foreign bodies from this organ, and the treatment of stricture of the urethra, in one case by permanent supra-pubic drainage, and its ...ture, also receive illustration. Three cases of ruptu... bladder, two intra-peritoneal, terminating fatal ...nto the vagina, with other severe injuries, treat... are recorded, and a case of exploration of the k... cision for abscess or for the removal of a... ve surgery has been well exemplified in ...ompound fractures of the humerus, fe... alus, the ultimate result in the sav... ful limb having been most sat... of the knee; the removal of loose ...ent over eighty years of age; the course ...t of cysts in connexion with this joint; ex... e elbow-joint and of the hip-joint; amputation ... the hip, followed by recovery; diseases of the bones, acute and chronic, in one extensive removal of tarsal bones leaving a useful foot; new growths affecting the neck, jaw, inguinal region, vagina, popliteal nerve, and skeleton, including one of the femur, recovery following amputation at the hip-joint; excision of cyst of the thyroid and of the thyroid itself; penetrating wound of the abdomen, the wound being enlarged for diagnostic purposes; wound of the neck penetrating the air-passages, in which suture of the air-tube was practised. Also cases from more speci... ...ases of the eye, throat, and

Commissions.

One of the most useful pieces of work undertaken during the year was that which related to the pollution of the Thames at the Henley Regatta. Our Commissioner visited the river at the time the regatta was held, and, as the result of his inspection, publicity was given in our columns to the abundant opportunity for river pollution afforded by the numerous house-boats which are brought together on this occasion. The majority of these boats have closets on board which drain directly into the water. Direct drainage of houses into the Thames is prohibited, but the river receives from house-boats large quantities of matter of the same character as that which is forbidden from other sources. But this is not all; the whole of the animal and vegetable refuse and the débris of the kitchen is thrown into the water, and thus the Thames, which supplies many of the inhabitants of the metropolis with drinking-water, is periodically polluted to a serious extent, and is liable to become contaminated in a manner which would not only affect the health but even the lives of those who depend upon it for their water-supply. It was time that the attention of the responsible authorities was directed to this danger, and it may be hoped that the steps which are now being taken by the Thames Conservancy Board as the result of our report will be the means of preventing a grave calamity in the future. Our Commissioner has shown the need for a systematic scavenging and for the punishment of all persons who may, in their disposal of animal and vegetable refuse, pollute the water of the Thames. It is by the enforcement of these measures only that safety can be ensured.

The sanitary condition of Windsor, to which we had given much prominence during the previous year, again came under our notice owing to an outbreak of small-pox in those parts of the town which had been the subject of previous articles. The freedom of any community from this disease is doubtless dependent in the first instance upon the condition of the vaccination of the inhabitants, but there is much reason for believing that other conditions [illegible] to overcrowding and absence of means of isolation [illegible]ed. [illegible]rtant factors in leading to the dissemination [illegible]t in [illegible], and Windsor appeared to afford special facili[illegible]ts of [illegible]itions for its propagation. At the present mo[illegible] which have [illegible]our Commissioners have led to an official [illegible]n elucidate [illegible]pol, a[illegible]al Government Board into the sanita[illegible]victe[illegible], and as to its defences against im[illegible]-servi[illegible]s seen [illegible]h, therefore, to discuss this matte[illegible]broth[illegible]ool [illegible]ear, [illegible]e [illegible]l used. [illegible]all rejoice to see effective measures [illegible]LLARely [illegible]ing Windsor fit in every sense of the [illegible]roi[illegible]me for the QUEEN, and for those of her s[illegible]d, exce[illegible]ndwell in the neighbourhood of her castle.

A serious outbreak of measles at Marlborough College gave origin to a special report from one of our Commissioners. A similar inquiry was made a number of years ago, and the condition of the College at that time was fully considered. It was convenient therefore to learn how far the school authorities had kept pace with the requirements of more recent knowledge, and it was with pleasure we were able to report that they had to a large extent been mindful of the health of the boys. Nevertheless, certain defects were found which demanded remed[illegible] and these, we are now glad to be able to say, have [illegible]

of th[illegible]ct [illegible] that we would desire to see done [illegible]mpleted, but we willingly acknowledg[illegible]e [illegible]n which has been given to our Commissi[illegible] [illegible] which [illegible]

An [illegible]f Commissioners in the course of the summer visited [illegible]r, with a view to ascertain whether the immun[illegible]andi[illegible]at town from small-pox is really as independent [illegible]vaccination as some would have us believe. He demonstr[illegible]at h[illegible] on the contrary, that the opposite is the case; that [illegible] the officials who have to deal directly with the small-pox of Leicester are vaccinated and revaccinated, and that very strong pressure is applied to all persons around those affected with actual small-pox to be revaccinated, and that apart from this prime precaution all other measures would be mere mockery.

Medical Honours.

The honour of knighthood has during the past year been conferred upon WILLIAM TURNER, M.B., DYCE DUCKWORTH, M.D., and B. W. FOSTER, M.D., and was offered also, but declined, by Mr. SAVORY, President of the Royal College of Surgeons, on the occasion of laying the foundation stone of the new Examination Hall on the Embankment; also upon Surgeon-General T. LONGMORE, Dr. E. H. SIEVEKING, the late Mr. W. WHITE COOPER, Dr. DOUGLAS MACLAGAN, and Mr. JOHN TOMES. Deputy Surgeon-General J. BY COLE READE, Brigade Surgeon GEORGE FARRELL, and Deputy Surgeon-General JOHN M'NEALE DONNELLY, M.D., were appointed members of the Third Class or Companions of the Order of the Bath; and ARTHUR MITCHELL, M.D., and WILLIAM ORANGE, M.D., were appointed members of the Civil Division of the Third Class of the said Order. Surgeon-General MICHAEL CUDMORE FURNELL, Deputy Surgeon-General ALEXANDER MORISON DALLAS, GEORGE WATT, M.D., and JOHN W. TYLER, M.D., were appointed Companions of the Order of the Indian Empire. Deputy Surgeon-General STEWART AARON LITHGOW was appointed a Companion of the Distinguished Service Order.

Obituary.

The painful part of the retrospect of a year is that which recalls those who have been taken away. Few years have been more cruel in this respect than the year 1886. The following names will suffice to justify this charge. They are taken from all branches of practice and all parts of the empire:—Mr. JOHN BLACKETT JEAFFRESON, Dr. F. G. JULIUS, Mr. WILLIAM BOUSFIELD PAGE, Dr. JAMES BALLS WOOLBY, Dr. R. ROBERTS MADDEN, Dr. ANGUS MACDONALD, Dr. GAVIN MILROY, Mr. COOPER FORSTER, Dr. JOHN STORRAR, Mr. C. LE VESCOMTE GODFRAY, Mr. JOHN S. STREATFIELD, Dr. E. O. P. CHARD, Dr. EVORY KENNEDY (Dublin), Dr. JOHN MATTHEWS, Dr. TIMOTHY LEWIS, Dr. SCOTT ORR (Glasgow), Dr. HENRY MACCORMAC (Belfast), Mr. FRANCIS MASON, Dr. JAMES APJOHN, Dr. WALTER MOXON, Mr. THOMAS WARD JESTON, Dr. ROBERT FOWLER, Dr. CHARLES CHADWICK, Mr. J. SAMPSON GAMGEE, Dr. SAMUEL WOODMAN, Mr. HIBBERT SULLIVAN PARKER (Ferozepore), Dr. J. PEARSON BELL, Dr. JOSEPH E. MILLER (Derry), Dr. FREDERIC JOHN FARRE, Dr. ARTHUR WYNN WILLIAMS, Dr. MORTIMER BALDING, Dr. NORMAN CHEVERS, Dr. WALTER FERGUS, Mr. W. A. N. CATTLIN, Dr. LYONS, and Dr. EBEN. WATSON. We dare not yield to the temptation to descant [illegible]

medical life and its labours ...lified in the foregoing names. They do... list of losses which our great profession ...even in our own country. But how suggestive... Some of the above had completed their course... ...DEN of Dublin, a great friend of the slaves wh... ...ica, was eighty-eight years old. Dr. APJOHN, ...ublin, was ninety-one. Mr. JESTON of Henley-... ...es was ninety-six, and his biography says he retire... ...active work about two years before his death, th... ...conveying a gentle rebuke to the young men of this degene...ate age who begin to think of retiring twenty years before this. The life and character of Dr. MACCORMAC of Belfast were among the most useful and interesting which we have recorded. The writer of the notice thought him at his death the oldest medical practitioner in Ireland, but we have since recorded the death of Dr. JOSEPH E. MILLER of Derry, which occurred in his ninety-fourth year. This remarkable man graduated in Edinburgh seventy-one years ago. He had been Mayor of Derry seven times, and had been in actual practice sixty-seven years. ...t is impossible to begrudge rest to those who have worked so long. We may be thankful that so many of the deaths recorded were at an age when life is practically over. But not a few have come all too soon, and removed those who promised fair to hold high the light of medicine for many a year to come. The death of Dr. AUSTIN FLINT must be mentioned as almost a domestic event, so familiar had become his face and work at home—from which, indeed, his ancestors went out.

The year has had a very special grief for ourselves in the death of Dr. JAMES G. WAKLEY, for more than twenty years Editor of this Journal, and under whose rule it attained to a more extended influence than it possessed even in the time of its founder. Dr. WAKLEY had a wide view of the functions of a Medical Journal, and thought Medicine a very large word in its meaning. It will be the part of those of his family who assume his responsibilities in the conduct of THE LANCET to be faithful to its traditions, and to remember the independence and courage in which it had its origin. The customary announcement on the title-page issued with this number is absent, in consequence of Dr. WAKLEY'S lamented death on the 30th August last; but we may here state that THE LANCET is now edited jointly by the present proprietors, THOMAS WAKLEY, F.R.C.S. Eng., and THOMAS WAKLEY, junior, L.R.C.P. Lond.

Next to Dr. WAKLEY'S interest in THE LANCET was the interest he felt in Hospitals, and especially in Hospital Sunday, of which he was a chief promoter. It was no little consolation to him to have assisted, as he was able, to raise the collection of this year to the sum of £40,000—a much larger figure than had before been realised.

Conclusion.

We must now leave our readers to the more cheerful duties of the season, with every wish for their happiness and prosperity. If our penultimate words have lessons of sadness in them, our last words shall be words of good cheer. Many a life has been spared to brighten the Christmas which but for the medical art would have been lost. Thousands are now alive who but for Medicine in some of its branches would have passed over to the majority. It is no mean distinction to belong to a profession which has such satisfactions, and whose services to humanity are ever growing in fruitfulness and beneficence.

Annotations.

"Ne quid nimis."

THE CONJOINT COLLEGES AND MEDICAL DEGREES.

IN our last week's issue we published the report of the Committee of Delegates appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England "to consider the question of the desirablity and practicability of granting degrees in medicine and surgery to persons who have passed the conjoint examinations of the two Colleges." We think that all our readers will agree that the report is a forcible and judicious statement of the singularly anomalous position in which the London student is placed, and that the demand for its removal is put forward on a sound basis, and in a strong but temperate manner. The only points in the report to which exception could be taken are (1) that residence in London for the whole clinical curriculum is not insisted on; (2) that the powers of granting degrees should be given to the Colleges acting conjointly, without any extraneous governing body; and (3) that the examinations of the Colleges in the subjects of study comprised in their curriculum are on a level with those of the majority of the universities of the United Kingdom. On the 16th inst. the report of the delegates was presented to the governing bodies of the two Colleges for adoption. The Council of the Royal College of Surgeons made some verbal alterations, and then referred it back for the further consideration of the delegates. At the comitia of the Royal College of Physicians of London, where the graduates of the existing Universities are in full strength, an interesting debate took place, and was resumed on the 23rd inst. During the course of the debate Sir George Paget demurred to the statement of the delegates as to the equality of the examinations; but it was pointed out that, besides Cambridge, Oxford, and London, there were many other Universities holding medical examinations in the provinces, in Scotland, and in Ireland, and these examinations were fully weighed by the delegates before the statement was passed by them. Moreover, professional examinations only are referred to, and a proviso was inserted into the first resolution for the institution of "such examinations in arts and science as may hereafter be defined;" and it is in arts and science ...he examination requirements of the Conjoint Exam...rd are inferior to the average University stand... President, Sir William Jenner, ruled that the Colle... ...on on the 22nd of October, 1885, was pledg... ...ees, acting conjointly with the College of S... ...en accepted the amendment of Dr. W... ...able that persons examined by the R... ...sicians of England and the Royal Col... ...land conjointly, and found duly qua... ...ry or by an additional examinat... ...gree in medicine and surgery con... From this decision the College could... only question that remains for settlement i... ...d the line taken by those who object to the ...ing a degree is indicated in Dr. Allchin's amen... ...e first and practically all-important resolution—"That no scheme for conferring degrees in medicine and surgery upon candidates who have passed the examinations of the Examining Board in England shall be deemed satisfactc... *...ess it provide for the conferring of degrees by some unive... ...only outside the Colleges themselves*, but on which they ...be represented." In October, 1885, Sir Risdon Benn... ...d an amendment by which the College would have pledged itself to support to the utmost of its power the scheme for a teaching university in London, and it was lost by a large majority. Dr. Allchin's recent amendment seems to us ... a transformation of this old ...assed, ...se would have stultified

itself; its rejection has involved the College in a second and a fruitless debate on the same question. The postponement of the movement until a teaching university shall have been formed is impossible, for only the medical faculty—and that practically consists of the London teachers, well represented at both Colleges—has decided on its wants. Arts, science, and law, as distinct faculties, are non-existent—or shall we say *in nubibus*?—and must be composed in the two former faculties almost entirely of the professors and members of King's and University Colleges, and even these, *teste* Professor Lankester, do not too cordially assist in maturing a scheme which will embrace the proposals of those associated in promoting a teaching university. Eminent lawyers are conspicuously few. The basis on which the College degrees should be granted ought to be wide and academical, and powers should be carefully drawn up so that other faculties may join with and enlarge the new university; but to delay application for these powers through an amendment drawn up in behalf of a non-existent university, in whose support only about thirty members could be got together at the last meeting for its promotion, and many of those included in its executive, seems to us to be nothing less than simple obstruction.

We congratulate the Council of the Royal College of Surgeons of England and the Fellows of the Royal College of Physicians of London on having come to so speedy a decision in support of the movement for granting medical degrees to London students on terms similar to those on which they are obtained elsewhere. The disadvantages under which London teachers and those who study medicine in London have hitherto been placed are now in a fair way towards removal, and some progress can be reported. The next step will be an application to the Crown for powers to grant such degrees, and so a distinct advance towards the foundation of a new university in London will have been made. It remains with the teachers of science and arts to decide whether this is to be composed of one faculty or of more than one, and we recommend to their notice the business-like energy and promptitude which the combined Colleges have shown as an example which they might well imitate if they are to share in the movement.

THE MORAL OF THE DIFFICULTIES O[illegible]TS.

THE meeting at the Mansion House to [illegible]ed. [illegible]000 for Guy's Hospital is a serious historical fa[illegible]t in [illegible] be deeply pondered by all persons. All the [illegible]ts of [illegible]od, but that of Cardinal Manning was the [illegible] which have [illegible] of the case from the religious point of vie[illegible] elucidate [illegible] immediately by Mr. Leopold de Roth[illegible]duc[illegible]ter[illegible]ool, [illegible] so; for this great duty rests with [illegible]y[illegible]t has [illegible]een [illegible]; it is enforced in no particula[illegible]r serv[illegible] W[illegible]roth[illegible]ool [illegible]ae burden of the Old Testament and [illegible]han[illegible]e[illegible]ed. [illegible]h Jew and Christian, and he would[illegible]LLy[illegible]ely [illegible]ner exponent of the principles of univer[illegible]ro[illegible]m[illegible] two who most showed that he felt the[illegible], except [illegible]spitals to weigh upon his mind, forbidding [illegible]oy rank or wealth till these are furnished w[illegible] can lessen misery and heal disease. We may [illegible]o once to the solution of this great difficulty. It is very easy. It can only be done by great gifts; and these can only come out of great accumulations of wealth, such [illegible]ge at [illegible]losophers condemn as bad for the State and bad for th[illegible]ividual, who is apt to get buried in them. No substan[illegible]lief will come to Guy's Hospital or to the other hospi[illegible]London if Guy's generosity be not imitated. This sum is [illegible] to be raised in driblets, nor are the ever-accumulating debts of the unendowed hospitals to be so reduced. We want gifts like that of Guy's. We have been [illegible]stimulating of late years the art of getting money. [illegible]ify[illegible] what [illegible]not [illegible]nis [illegible]nger of soon having no hospitals availa[illegible]s [illegible]dly realised by thousands of sick poor the[illegible]a[illegible]in hospitals and are not. Is it not a most [illegible]which that the poor of the south side of the Thame[illegible]h[illegible]ve[illegible]ident for their hospital accommodation main[illegible]on[illegible]? who lived a hundred and fifty years ago, who [illegible]s[illegible]im[illegible]kseller's shop, and who took his dinner off his cou[illegible]and[illegible]ired with a newspaper for his tablecloth. Neither [illegible]ver[illegible]neglect or forget his friends, but within a fortnight[illegible]at h[illegible] death the hospital was open and sixty poor patients w[illegible]esting on the beds which his kindness had provided. [illegible]t a monument he has still! What a glory there is in such gifts, even as there was in the pagan world—"namque et titulis et fascibus olim major habebatur donandi gloria." There is no serious fault to find with the administration of Guy's Hospital, though if the public are to be asked to support it, the public must be admitted to the councils and the confidence of its authorities. We shall watch with some anxiety the result of the appeal of the Lord Mayor and his supporters. The times are critical for the great hospitals, and for the very system on which they exist. Wealth persists in increasing; if the *gloria donandi* increases with it, all will be well.

METROPOLITAN ASYLUMS BOARD.

AT their meeting on Saturday last the Metropolitan Asylums Board had again before them the question of building a permanent hospital at Darenth, the subject being brought under their consideration by various boards of guardians who had written protesting against the proposed expenditure. The chairman, Mr. Galsworthy, pointed out that the managers were not now seeking, as had been represented, to expend £84,000, but had adopted a resolution which did not specify any definite sum. Sir Edmund Currie made a final effort to induce the Board to depart from its previous decision, but without avail. We cannot but think that in these differences the managers are losing sight of the more important question of the planning and construction of the hospital. The desire of the Local Government Board that only temporary buildings should be erected can only mean that permanent buildings such as have been provided elsewhere have failed in their object, and that they are unwilling that the managers should incur the larger expenditure of a permanent hospital before a definite opinion has been formed as to the proper method of its construction. The Asylums Board at a later stage of the meeting adopted a report of their Ambulance Committee, which promises to confer a great benefit upon the metropolis. The ambulances of the managers are now limited in their use to the removal of infectious cases to their hospitals; they have now expressed their willingness, if the power be conferred upon them, to undertake the general removal of all such cases throughout the metropolis, whatever may be their destination. This is the only effectual method by which the use of public conveyances can be prevented, and the managers rightly point out that it would be then possible and necessary to constitute as an offence the use of any street cab for the removal of a person suffering from infectious disease.

THE LESSONS OF THE CAMPBELL CASE.

THERE is only one reflection to be made on the Campbell case which it seems worth while to offer for public consideration, at least at this conjuncture—namely, that the purity and consequent happiness of social life are not advanced by the law and custom which force these exposures of domestic infelicity on public attention. It is not for the good or improvement of the community that a large portion of the news of the day [illegible]ist of

such recountals as the daily pap… during the last few weeks. Those who do… least edifying of news columns must be heat… that the feast of unreason has at length come t… congratulate Mr. Bird on his emancipation from … bondage which must have been worse than p… and we trust the wrong and humiliation thro… respected member of our profession has pas… soon be forgotten. It seems to be the too common l… men to be maligned and tortured by those who … debt of gratitude for services cheerfully rendered. T… ads us to remark that one, and not the least forcible, lesson of the Campbell case is that which we have so often tried to teach in these columns—that medical practitioners act wisely when they do not make friends of their patients, but treat their friends strictly professionally. The several relationships of *friend* and *medical adviser* are not socially compatible. The one position ought to be abandoned when the other is assumed. It is in the confusion of the two characters that difficulty and scandal take their rise. Another lesson, scarcely less hard to learn, but not a whit less important, is the unwisdom, both from a personal and a professional point of view, of medical men appearing in court to support or oppose particular lines of evidence. When counsel pit one medical witness against another the prestige of the profession is sacrificed. It is so not only in cases of the class to which we are now alluding, but whenever and wherever medical evidence is produced to bolster up a plea or line of argument, whether of accusation or defence, that wrong is done. It is of course unavoidable that medical practitioners should appear in court; but when they do, we are strongly of opinion that it should be only as witnesses of scientific fact, and as far as possible fact known or ascertained, before a legal issue is raised. Otherwise there can scarcely fail to be *petitio principii* or *suppressio veri*, either or both; not, as is hastily and ignorantly assumed, because medical witnesses are unscrupulous, but because the forensic method and practice will have it so.

ACTION OF DRUGS IN ALBUMINURIA.

AN interesting communication on this subject was read in the Section of Therapeutics at the Brighton meeting of the British Medical Association by Dr. Robert Saundby. He pointed out the difficulty of foretelling what action drugs might possess on the renal processes in genuine albuminuria. The number of drugs with which he experimented was very large. The following are his chief conclusions:—Alkalies used in the form of diluents—such as a quart of bitartrate of potash imperial (one ounce and a half to a pint), daily, gave distinctly favourable results in cases of chronic persistent and copious albuminuria. He has employed … citrate of lithia, bicarbonate of potash, ammonic … and bicarbonate of soda, and includes them in the favourable opinion. The beneficial effect was not due to the formation of alkali-albumen: for Esbach's fluid, which was the method employed, precipitates that form of albumen. Tannate of soda, or rather an ounce mixture of tannic acid and bicarbonate of soda, of each ten grains, with fifteen minims of glycerine, also gave good results. In one case the albuminuria was diminished nearly one-half. Nitroglycerine and fuchsin appeared to have no good effect. Digitalis and other heart tonics—caffeine, strophanthus, sulphate of sparteine, iron salts, acetate, sulphate, and perchloride—increase the amount of albumen passed. Apocynum was not found to have any diuretic action in drachm doses of the tincture, and it increased the albumen in two cases. Turpentine had no beneficial effect, though hæmaturia followed its employment in one-minim doses. Doses of the 1000th of a grain of bichloride of mercury were also inoperative.

TESTIMONIAL TO SIR ANDREW CLARK.

A TESTIMONIAL to Sir Andrew Clark is proposed, and will doubtless be carried to a successful issue. The proposal was occasioned by his recent retirement from the more active duties of the office of physician to the London Hospital. A committee was formed consisting of the President of the hospital, H.R.H. the Duke of Cambridge, members of the medical staff, governing body, and students of the hospital, to carry out the wishes of the promoters. Though the movement naturally emanates from the London Hospital and its medical school, with which Sir Andrew's name is so honourably and indissolubly associated, and the committee will consist of gentlemen connected with one or other of these bodies, yet it is believed that many of the public and of the profession, quite unconnected with the hospital, will be glad to contribute. Sir Andrew is not a mere physician or teacher of medicine. He is more than any other consultant a public man, who, with marvellously little consideration for his own convenience, meets the public for the discussion of current questions in which his special knowledge and experience may be of use; and on such occasions he is ready to take as well as give. He has an ear for public opinion as well as an opinion of his own, which he expresses with equal lucidity and conviction. His form and speech are among our familiar impressions, and his medical dogmas are tempered with a human element, which makes them more effective and acceptable. It may well be that the public will be glad to honour such a member of the profession, who considers not himself when he can be of any use to the public; and we have only to express our hope that the movement, of which Mr. John Henry Buxton is the treasurer, may be very successful.

QUEEN'S COLLEGE, BIRMINGHAM.

DR. SUCKLING concluded on Tuesday last his post-graduate lectures on the Diagnosis and Treatment of Diseases of the Central and Peripheral Nervous System. The delivery of such a course was more or less of an experiment, and, judging from the large attendance (averaging over seventy-five), may be considered as a complete success. The lectures have … dered additionally interesting, as well as instruc… e exhibition of forty living cases designed for t… n of special portions of the course. These incl… udo-hypertrophic paralysis in the child and … muscular atrophy of various types, fa… ypical cases of locomotor ataxy, … cramp, &c. During the course … Eye Hospital, demonstrated the use … perimeter in the diagnosis of … a number of illustrative cases. … onstration of pathological speci… ject of the course was given. It … uccess of this course will lead to … thers from time to time.

RESCI… OF THE MUZZLE ORDER.

HAS Sir Charles … ren acted with sound judgment in rescinding the pol… der for keeping the dogs of the metropolis under pr… ntrol? We doubt whether he has considered the mat… h sufficient care. It is a popular fallacy to suppos… ydrophobia cannot be epidemic during the cold … The wolves of cold countries are not less harmful … periods of greatest depression of the thermometer; … and the bite of a mad dog is likely to be as lethal in the wi… tors in the hotter months. Further, … are am… nt th… k that the police order has not … ency to effect any great

and lasting result. Many stray dogs have disappeared from our streets, and for this partial clearance we must at least be thankful. But it would certainly have been more for the good of the greater number, not only of the canine but of the human race, if the police order had remained in force for some time longer. And still more would the utilitarian principle have prospered if the law were effectively enforced for a sufficient length of time in the whole of the dominions, states, and empires of the world wherein rabies had been known to occur. Does it not savour somewhat of the ridiculous that Nottingham should have recently adopted the muzzling order which in London has just been withdrawn.

LOCAL GOVERNMENT.

THE subject of Local Government has evidently been seriously considered by the Cabinet, for Mr. Ritchie has announced his intention of bringing before Parliament during the coming session this long-expected measure. The speech made at the annual dinner of the Melksham Agricultural Society by Mr. Walter Long, M.P., Parliamentary Secretary to the Local Government Board, gives some information with regard to the constitution of the authorities which are to be called into existence. These are of course to be representative, but by this word is meant that the various interests which will be affected by the action of the authorities are to be represented upon them. No more difficult task could be undertaken than to carry into effect this intention; the very proposal to constitute authorities upon these lines invites criticism which may be found to seriously imperil the safety of the Bill. It may be expected that the more Radical members of Parliament will desire to accept the present basis of election as that which should be adopted in any further legislation, but local authorities have in many districts disappointed those who hoped for efficient work, and some other change than the mere alteration of their powers and the boundaries of their districts is evidently needed. We shall await the publication of the Bill with much interest, but there is, we fear, little hope that the consideration of its provisions will this session receive the attention of the House. The more urgent questions of Procedure, of Irish Government, and of Supply will afford too many opportunities for the expenditure of time to warrant the existence of any hope tha[illegible]ent will be able so soon to express any opinion up[illegible]ed. [illegible]e's measure.

THALLIN IN TYPHOID.

THE introduction of such drugs [illegible] which have and "antifebrin" has somewhat [illegible] very powerful antipyretic agent [illegible] Ehrlich lately presented to the [illegible] the results of some researches he [illegible] last-named agent, especially in [illegible] fever. (*Münch. Med. Woch.*, No. [illegible] he had found that after administer[illegible] it was not retained in the nerve [illegible] fatty tissue of the body. He also [illegible] marked difference in toxic action, [illegible] was administered by the mouth or subcut[illegible] inertness of its effect in the former [illegible] to the hindrance to absorption from [illegible] tinal contents. The lesions induced [illegible] fatty degeneration of the kidneys, [illegible] glands and pancreas, and hæmorrh[illegible] pyramids. The chief action of th[illegible] is antipyretic, but it is capable also of moderating inflammation. As regards typhoid fever, it was administered by Ehrlich in two different ways. The first plan consisted in commencing with doses of 0·06 gramme [illegible] dose [illegible] tired to give any effect. The other [illegible] sence with a minimum dose, and increa[illegible] effect was produced, and then to contin[illegible] which ption at the dose thus attained. The action [illegible] is especially noticeable in its effect on the sens[illegible] general condition of the patient, who presents the appearance of convalescence, whilst the splenic swelling and rose rash still present; and if the drug be discontinued the temperature will rise again. It is not therefore surprising to find that, whereas of twenty-eight cases treated by [illegible] the average stay in hospital was thirty-seven days, [illegible] seven cases treated by thallin (minimum doses) the duration of treatment was forty-seven days, and cases on a scale of progressive doses thirty-eight days. However, Professor Ehrlich claims advantages for the drug in the absolute control it exerts over the pyrexia, and the sense of well-being enjoyed by the patient. There were no intestinal hæmorrhages in these cases, and no instance of perforation. The kidneys were not affected, but sequelæ in the form of hyperæmia and œdematous swellings seemed due to the use of the drug. It was not thought that thallin had any specific action against the typhoid bacillus, but it did seem to limit the degree of intestinal ulceration. Professor Ehrlich considers it to be on a level with the bath treatment. Dr. Fränkel pointed out that if the statement were correct that thallin is not found in the nerve centres its action in reducing temperature was rather inexplicable. He had exhibited it in increasing doses, but could not say that the patients experienced any special benefit attributable to the diminished fever. Dr. Guttmann had not been favourably impressed by its use, and had noted the production of rigors.

THE GOOD SERVICE PENSIONS.

A MEDICAL good service pension of £100 a year has become vacant through the death of Sir James Salmon, I.G. It is one of three established in 1859, by warrant, "to be awarded to the most meritorious medical officers of the Royal Navy, under such regulations as shall from time to time be determined on." They have been hitherto awarded to a succession of retired officers of the rank of I.G., and the pension now vacant will in all probability fall to Sir William R. E. Smart, K.C.B., K.L.H., retired I.G., who has obtained his decorations and the appointment of honorary physician to the Queen in recognition of his meritorious services. Sir William is the author of important and interesting papers on epidemics and diseases prevalent in the Navy and in tropical climates, of which many are to be found, in full or in abstract, in our pages.

THE HIGHER EDUCATION OF THE BLIND.

AMONG the possible higher developments of education there still remains at least one neglected sphere in which no adequate provision has been made. This is the establishment of some system of instruction for blind youths of the upper classes. The sons of poorer men are in this respect comparatively fortunate, inasmuch as they possess in specially appointed institutions that stimulus to learn which comes of intercourse with fellow-learners. Public sympathy has naturally first attended to their needs. It is apt to forget that their wealthier brethren have need of the same companionship and scholastic method in prosecuting studies of a higher order. At present there exists but one school, Worcester College, which aims not unsuccessfully at meeting these requirements. Even this establishment is unendowed, and exists only as a private venture. That it ministers to a felt want is undoubted, and that it should remain possessed of no more certain means of maintenance is therefore the more to be regretted. At a meeting held last week in the church-room, St. Jude's, South Kensington, an important

step was taken towards its surer ... ...intment of a committee entrusted with ...ing £6000 required for this purpose. We ... ...that a part of this sum has already been promis...

HYSTEROGENIC ZONES ON MUCOUS ...CES.

ATTACKS of a spasmodic or of a leth... ...re in hysterical patients can often, as is well k... ...cited by touching or pressing upon certain spo... ...n the surface of the body. These external "h... ...ic" zones were examined and described by M. Gaube, and later by M. Blanc-Fontenille. Quite recently, too, M. Lichtwitz, who had been asked by M. Pitres to examine a hysterical patient laryngoscopically, observed that a severe convulsive attack was produced by touching the epiglottis, and subsequently by examining the mucous membranes of half a dozen hysterical patients he has been able to show that hysterogenic zones exist there as well as on the external surface. In all the six cases the nasal fossæ were the seat of spasmogenic zones, which were bilateral except in one instance, in which touching th... ...al mucous mem... ...on one side produced ... hypnotic ...ack. In four cases either spasmogenic or lethargogenic zones were found in the laryngeal mucous membrane, the posterior wall of the pharynx presenting one instance of each kind. The mucous membrane of the gums, the conjunctivæ, and the external auditory meati also furnished "zones." In some of the cases the sensitiveness was obliterated by cocaine, so that necessary therapeutic applications could be made; in other cases the use of cocaine did not succeed. In one case, in which the leg was in a plaster bandage, where a violent attack might have proved serious, a convulsion, which was accidentally induced by ...uching the mucous membrane, was arrested immediately ... a friend whom the patient had brought with her, who was acquainted with her external spasmo-inhibitory zones.

THE CHAIR OF MATERIA MEDICA AT ABERDEEN.

THE following gentlemen are, we understand, candidates for the above chair:—Dr. John G. Hall, assistant to the Professor of Materia Medica in the University; Dr. J. C. Ogilvie Will, surgeon to the Infirmary; Dr. Gordon, assistant-surgeon, Sick Children's Hospital; Dr. Robert M. Wilson, Old Deer, formerly Assessor Examiner in Materia Medica and Botany in the University; Dr. Leith Napier, assistant to the Professor of Materia Medica, University of Glasgow; Dr. R. Stockman, assistant to the Professor of Materia Medica, University of Edinburgh; Dr. Theodore Cash, assistant to Dr. Brunton, lecturer on Materia Medica, St. Bartholomew's Hospital, London; and Mr. Joshua Law Kerr, M.B., C.M. Aber., late assistant to the Professor of Midwifery in the University of Aberdeen.

MEDICAL EDUCATION IN MADAGASCAR.

IT is gratifying to learn from *Medical Missions* that an important advance has recently been made in the matter of medical education in Madagascar. There are now four medical missionaries in Antananarivo—Drs. Fox and Allen of the Society of Friends' mission, and Drs. Borchgrevink and Guldberg of the Norwegian mission. They have combined to form a board for medical education for the furtherance of the work of medical missions, and under the joint auspices of the missionary societies involved. A curriculum has been decided upon, and each student is to complete a five years' course. It is not to be supposed that hitherto no attempts have been made in the direction of medical instruction. Some of the pupils of Dr. Davidson, the first medical missionary to the Malagasy, are practising in Antananarivo and elsewhere. Dr. ... ...himself ... the last five years has admitted twenty-one students. Dr. Davidson during his residence in Antananarivo prepared manuals on therapeutics and systematic medicine, which are in regular use by the Malagasy students, and Dr. Fox is now preparing other manuals for their use.

SANITATION IN KILMARNOCK.

AN important report has been prepared by Dr. John C. McVail, the medical officer of health, on the proper disposal of the excreta and house refuse of the population of Kilmarnock. Dr. McVail very properly contends that excreta should, if possible, be removed from the vicinity of dwellings before decomposition sets in, and this condition would require removal every forty-eight hours. The danger of their detention for a longer period is naturally greater in the case of such diseases as enteric fever; and Dr. McVail holds the same view with regard to scarlatina. The evidence as to mischief from scarlatinal excreta is by no means clear, but we can well conceive that they may contain the poison of the disease, and it is certainly right to look with special suspicion on all diseased excreta. In Kilmarnock it is taken for granted that the watercloset system is not adapted to all classes of the population, and after acquiring experience as to the working of other systems in northern cities, the pail system is strongly recommended for adoption; one pail to receive excreta and to be frequently changed for a clean one by the scavengers, the other to receive house refuse only. In the case of the latter pail, and subject to the regular incineration of vegetable refuse in the ordinary fire-places, a less frequent removal is held to suffice than is necessary in the case of the excreta-pails. The alternative system of merely emptying the pails instead of substituting clean ones is referred to; but it is rightly condemned. Wherever it exists the excreta-pail soon becomes foul, and hence the main advantage of the system, in so far as the prevention of nuisance and risk to health is concerned, is practically lost. Such a report as that prepared on the subject by Dr. McVail deserves, and will doubtless receive, the careful attention of those to whom it is addressed.

AFTER-CARE FOR MENTAL CONVALESCENTS.

THERE ...cially great difficulty in the management of convale... ...l mental disease, and we are glad that the propos... ...uitable half-way houses between the asylum... ...s taking a practicable shape. It is, howev... ...ast importance that what is done shoul... ...l support, and be benefited by the ... ...perintendents of asylums. D... ...AT SHIRLEY.

AN ou... ...eak of ... has been prevailing in Shirley, a suburb ... ...e new... ...ed borough of Croydon, and by the inhabi... ...s of the ...y affected the disease is very generally at... ...buted t... ...fective means of sewer ventilation. Indeed, the o... ...uing from the man-holes are described as horrible... ...public meeting a request was ordered to be conve... ...Mayor, asking that an independent sanitary e... ...ight be appointed to inspect and to report upon th... ...n of sewers. It is somewhat unfortunate that this ...was not complied with, for whatever the ...ause ...theria may be, it seems pr... ...ments as to sewer

ventilation are faulty. There are, however, sanitary officials in Croydon who are quite able to investigate the source of the prevailing disease, and also to advise as to the proper remedies.

UNIVERSITY OF LONDON.

A MEETING of Convocation of the University of London has been summoned for January 18th, when no doubt an interesting statement as to the relations of the University to the present position of the question of medical degrees will be forthcoming.

AN ARTIFICIAL RAMUS AND CONDYLE.

DR. CUNNINGHAM, at the last meeting of the Odontological Society, showed a very ingenious apparatus invented by Herr Rosenthal, which was designed to meet the following difficulty. The ramus and condyle of the lower jaw having been removed for a sarcoma, it was subsequently found that the other side became dislocated, and, after reduction, for which an anæsthetic was required, slipped out again immediately. Gold bands were fitted accurately to the last molar of each jaw on the side where the bone had been removed, to the upper of which a thick slightly curved wire was soldered. This wire fitted loosely into a tube soldered to the band round the lower tooth, and the bands themselves were fixed to the teeth by screws tapped into them. The apparatus entirely prevents the dislocation, and although there is no lateral movement the patient can eat fairly well.

ST. ANDREWS UNIVERSITY.

A MEMORIAL from the Senatus Academicus of the University of St. Andrews has (as was stated in our last issue) been presented, setting forth the claims of the University to such an increase in the staff of its medical professors as would enable it to give two *anni medici*, the period of residence required by the Scottish Universities for medical graduation. A memorial to the same purpose is in course of preparation from the graduates of the University, and is being largely signed, some 800 having already appended their names.

BACTERIOLOGY IN BARCE[illegible]ied.

THE municipality of Barcelona has [illegible]t in [illegible]blish a laboratory of bacteriology, and [illegible]ts of [illegible] the requisite appliances for all class[illegible] which have [illegible]t is to be under the well-known D[illegible]r[illegible]e accepted much more generally in Ba[illegible]ol[illegible]l. The measure was agreed to in th[illegible]ty of twenty-five to three.

ANOTHER LUN[illegible]

THE Home Secretary is said [illegible]ration a proposal to deal with the la[illegible]atics. it find its way to the Statute-bo[illegible]ould, wi[illegible] or worth anything? We have dou[illegible]oo m[illegible]ssen[illegible] appointments.

ROYAL UNIVERSITY OF IRELAN[illegible]

OUR Dublin correspondent [illegible]. An election for a member of Senate will take pl[illegible] meeting of Convocation to be held on the 30[illegible]en it is believed that Mr. Stephen O'Sullivan, [illegible] Surgery in the Queen's College, Cork, will be [illegible]. There are four candidates in the field for the [illegible]. By the death of Dr. Lyons another vacancy o[illegible]ate has arisen, that gentleman having been [illegible] foundation of the [illegible]

UNIVERSITY INTELLIGENCE.

Bo[illegible] [illegible]estphal has just celebrated the completi[illegible] which [illegible]-fifth year as teacher in the University. The t[illegible] av[illegible] of students, including all the faculties, is the l[illegible] record, being 5357. Of these 1297 are medical studen[illegible]

Dorp[illegible] [illegible]anveiling of the Baer memorial has just taken p[illegible]ve[illegible]ne.

Gö[illegible] [illegible]at h[illegible] de[illegible]150th anniversary of the founding of the Universi[illegible]s[illegible] held next year.

Innsbruck.—[illegible]ser Government has promised to provide the funds for building a new Anatomical Institute.

Konigsberg.—The name of Professor Braun of Jena is now brought forward in addition to those of Drs. Madelung and Miculicz, as a candidate for the chair of Surgery. During the vacancy Dr. Stetter is performing both the clinical and the professorial duties.

Leipsig.—Professor Credé has intimated his desire to resign the charge of the Obstetric Institution, which he has held for thirty years.

Leyden.—Dr. Simon Thomas, Professor of [illegible]ifery, has just died at the age of [illegible]y-six, having held [illegible] professorship for nearly forty years.

Upsala.—An Extraordinary Professor of Anatomy is to be appointed, who is to occupy himself with Histology and Embryology.

St. Petersburg (Military Medical Academy).—Privat-docent Dr. A. Beltsoff has been appointed by the Conference (Senate) to take temporary charge of the Surgical Clinic of the late Professor Kolomnin. It is stated by the St. Petersburg correspondent of a Riga paper that Professor v. Bergmann of Berlin has declined an invitation to the St. Petersburg chair.

Granada.—Dr. Don Daniel de Zuloaga y Santos, Professor of Midwifery, has died from cerebral hæmorrhage, which occurred just as he was proceeding to his morning lecture.

WE regret to announce the death on the 17th inst. at his residence near Gosport, of Sir James Salmon. The deceased was born at Irvine, Argyleshire, in 1811, and received his professional education at the University of Glasgow. At the age of twenty-two he entered the Royal Navy as assistant-surgeon, becoming surgeon in 1840, Deputy Inspector-General of Hospitals in 1855, and Inspector-General in 1868, in which year he was knighted. Sir James was an honorary physician to the Queen, and was in receipt of a pension for meritorious services.

SIR WILLIAM STOKES (President of the Irish College of Surgeons), Dr. William Moore (ex-President of the Irish College of Physicians), and Sir George Bowens (a Governor of the Apothecaries' Hall), are candidates for the position of Crown nominee on the General Medical Council, in the room of the late Dr. Lyons.

THE Lettsomian Lectures will be delivered at the rooms of the Medical Society of London on the 3rd, 17th, and 31st of next month by Dr. J. Langdon Down. The subject of the lectures is "On some of the Mental Affections of Childhood and Youth."

THE Madras Government is about to engage in the cultivation of jalap. The demand this year from the Madras Medical Department was for 1300 lb., and only 400 lb. could be obtained from private growers.

SIR WILLIAM TURNER has been elected by the University of Edinburgh to represent that body in the General Medical

As will be seen by a letter fr[illegible]d in another column, the Apothecaries' [illegible]l Mr. R. Brudenell Carter to be its represen[illegible]eral Medical Council, in place of Mr. Bradf[illegible]n of office had expired.

DR. MULES, of the Manchester Royal Ey[illegible] has been appointed one of the Vice-Presidents in [illegible]almic Section of the International Congress to be [illegible]rming-ham.

THE next President of the Pathological [illegible]will probably be Sir James Paget, Bart.; and of th[illegible]cal Society, Dr. W. H. Broadbent.

THE cholera is very prevalent in Buenos Ayres and its vicinity. In Cordova on Nov. 30th there were twelve new cases and five deaths.

THE ROYAL COLLEGE OF PHYSICIANS AND MEDICAL DEGREES.

THE foll[illegible] is a brief repor[illegible] debate which arose [illegible] the meeting of Fellows of the College of Physicians on the 16th inst., on the motion that the first resolution of the report of the delegates be adopted.

Sir W. GULL said the terms of the resolution were too vague, it not being indicated what degree should be conferred. The College and the spirit of the time had determined that there should be some recognition given to London students beyond that conferred by the Conjoint Board; but no decision had been come to as to what should be the nature of that recognition or on what terms it should be given. Believing as he did that the tw[illegible]olleges constituted one of the most important medi[illegible] examining boards in the world, he considered the condition named in the report, that candidates passing the present examinations should have a degree conferred on them, "provided that they have passed such examinations in arts and science as may hereafter be defined," to be weak and inadequate. The Colleges should advance clinical medicine and surgery, and their degree should be based on excellence in these subjects. It was the only degree which they were competent to give, for it embraced the subjects for which they alone were responsible.

Subsequently Sir William moved an amendment to the effect that candidates who have passed the examinations of the Conjoint Board shall be admitted to a further examination for a degree in clinical medicine and surgery.

Dr. ALLCHIN moved—"That no scheme for conferring degrees in medicine and surgery upon candidates who have passed the examinations of the Examining Board in England shall be deemed satisfactory unless it provide for the conferring of degrees by some university body outside the Colleges themselves, but upon which they may be represented." He admitted that the question whether such candidates should have a degree or not had been settled; but the question remained how that principle was to be carried out. The report suggested a means, but except in one of the later clauses the idea that the degree-conferring body should be a university was curiously concealed. It was clear, however, that a university was contemplated; but how was it to be established? The report was not the result of a unanimous vote, and he was unable to reconcile its tenour with the expressions of the report of the Teaching University Association deprecating the proposal that the Colleges should grant a degree. Yet seven of the delegates who are responsible for the report were members of the committee of that Association. He contended that the statements in the two reports were absolutely contradictory, and pointed out that Professor Marshall at the meeting of the Association on the previous day had stated that if the Colleges adopted a scheme outside the lines laid down by the Association, it would be their duty to oppose it. He (Dr. Allchin) failed to see any reason why the Colleges should constitute the proposed university; the expression in Clau[illegible] that [illegible] natural way," being scarcely explicit; and in Clause 4, the statement that the curriculum of the Colleges is on a level with that of the majority of the universities is put forward as a reason why they should grant degrees. But there were very cogent reasons against this. In the first place, to convert the present Colleges as they stand into a university is against all precedent whatever. The mere fact of granting a degree is the least among the functions of a real university. Montpellier—which was cited as a precedent—existed as a teaching body. He contended that they had to deal in this question with the academic aspect of a university as distinguished from the corporation aspect. Further, the report was inconsistent in urging at one time the advantages of London as a place for clinical study, and therefrom arguing in favour of the scheme, and in the first resolution giving permission to the governing body to admit students who have pursued their work in other than London schools. Are the Colleges, he asked, to be merged in the university, or are they to go along side by side? Is the College of Physicians to grant the Fellowship with one hand and a degree with the other? Is its prestige to be buried in a new "University of Westminster"? The degree in contemplation must be an inferior degree, so that they were asked to constitute a second-rate university. He did not think he was bound to suggest an alternative scheme; but he maintained as a principle that the degrees should be conferred by a *bonâ-fide* university—an outside body. This, he could conceive, might be either the London University itself, or such a university as was contemplated by the Teaching University Association. It had not been suggested that any particularly higher standard should be insisted on; indeed, if it were, the object would be defeated. That object—viz., to keep students in London for clinical work—was minimised by the permissive clause of Resolution 1. The proposal was purely a professional one; and if the College took the steps demanded, it would detract from its honour and position.

Dr. NORMAN MOORE seconded the amendment. He said the report was the outcome of a very large number of compromises, and the delegates not being anxious to insist too much on their individual opinions, there was no minority report. There were two distinct views before the Committee—the one being that the public require a degree, and the other that the question of giving a degree should be based on the desire to improve medical learning. The minority held to the second view, the majority to the first. The College would have a difficulty in obtaining powers to get a degree upon the mere ground that practitioners are desirous of it; and he always held that the mere acquisition of a degree (e.g., that of Brussels) for its value as a title alone w[illegible]eption, making the public believe that there had b[illegible]versity education behind it. A university consi[illegible]who learn and people who teach; and the ti[illegible]en such a university can be established in Lo[illegible]njoint Board was formed, the College of P[illegible]o it on the ground that it was not co[illegible]miners in surgery; and on the s[illegible]petent for a medical board to c[illegible]arts and science? The Colleges sh[illegible]hing that is of value; but if th[illegible]would give what was worthless[illegible]College had the power to play a [illegible]versity in London.

L[illegible] to remedy an acknowledged grieva[illegible]r the institution of a teaching [illegible]ersity, [illegible]the first faculty of such a [illegible]rsity w[illegible]ned under the auspices of the [illegible]leges, [illegible]he basis would be widened. W[illegible]y to w[illegible]ence and arts teachers in the metrop[illegible] to co[illegible]n they had a concrete medical faculty [illegible]dy at [illegible]universities differed all over the kingdom[illegible]., Durh[illegible]s[illegible]ord, London, Edinburgh, Dublin; so that it [illegible]s absur[illegible] that there was only one type of university.

Dr. BRISTOWE p[illegible]t that the College decided last year that steps sho[illegible]n to give a degree.

Sir RISDON BE[illegible]no[illegible]red from Dr. Bristowe. Last year's resolution e[illegible]ur[illegible] the delegates to suggest some mode of obtaining[illegible]e, and did not bind the College to confer it.

The PRESIDENT s[illegible]t Dr. Moore was on the sub-committee [illegible]eport, and with respect to [illegible]body to include other

than London schools, it was felt that they ought to recognise any large clinical school outside London.

Dr. WILSON FOX pointed out that titles at present conferred by the Colleges were not regarded by the public as equivalent to degrees, although the profession were aware that they were not inferior. So long as a large body of English medical men were under that sense of inferiority, their profession suffered in dignity. The University of London for fifty years had been upholding the view that a degree in medicine is a stamp of knowledge; and, taking Edinburgh as the type of a medical university, he could not see that the relations under which students live there are at all different from those in London. It was entirely hopeless to appeal to the University of London, whose degrees were, as Sir James Paget had said, "honours degrees." The Edinburgh degree is a "pass degree," and what London wants is a good medical pass degree, to stamp a man as "learned in medicine." Turning to Dr. Allchin's speech, Dr. Fox asked whether the two Colleges were incapable and unfit to give degrees? It passed comprehension to see what the extraneous body suggested in the amendment is to do for the Colleges; and the alternative, that the Colleges would be merged in a university, was not necessary. He did not see why they should not retain their independence, and yet combine for this great purpose, and he could not see how they would be disgraced by so doing. This matter was very urgently demanded by medical students. They could hardly wait for the formation of a teaching university; but, at any rate, they could constitute a medical faculty, and leave the full development of the university to the future.

Dr. CHAMBERS disputed the statement in the report that the curriculum of the Colleges was on a level with those of the majority of universities, and showed by statistics that the best work was done by university graduates.

Dr. QUAIN asked how such degrees were to be conferred except by the Colleges. As to Sir W. Gull's objection, the scheme simply meant that the degree should not be inferior to a university test. The whole question of how it is to be done must be left over. He sympathised with the idea that the degree should be confined to London students, but saw difficulties in practically carrying it out. Dr. Allchin's amendment would set the two Colleges seeking for a body which has no existence.

Sir H. PITMAN moved, and Sir G. PAGET seconded, the adjournment of the debate.

The adjourned meeting took place on the 23rd inst., when there was again a very large attendance of Fellows.

Sir H. Pitman, in an eloquent and forcible speech, reminded the College of the steps previously taken in the matter, and pointed out that the opportunity was one which the College should not let go, for it would never recur. ... Dr. Andrews Duncan and Sir Risdon Bennett supported ... ment, which was opposed by Dr. Ord, Sir A. Cl... Dr. Dickinson, Dr. Latham, Dr. Barnes, Dr... Dr. Priestley. On a division, nine voted f... ts of ... endment, which was negatived by a w... which have ... in a full comitia.

The second resolution on the ... vi... ... be made to the Crown by the Royal ... ool, ... of London and the Royal Col... ... has ... acting conjointly, for power ... Wrot... ool ... and Surgery," was then move... than ... by Sir W. Gull, and carried unan... ... The first resolution and Sir ... referred to the delegates of the ... ther consideration.

VITAL ST...

HEALTH OF ENGL... NS.

IN twenty-eight of the largest ... towns ... births and 3805 deaths were registered ... the week ending Dec. 18th. The lowest rates in these to... by ... week were 11·9 in Derby, 12·1 in Brighton, 14·... ... ahead, and 17·1 in Birmingham. The rates in ... 27·6 ... ect ... verhampton, 28·3 in Norwich, and 3... ... deaths referred to the principal zymo... twenty-eight towns, which had been the ... the preceding two weeks, declined again ... which ... 886; they included 141 from measles, 77 from ... 54 from whooping-cough, 42 from "fever" (prin... ... ric), 37 from diphtheria, 34 from diarrhœa, and ... -pox. No death from any of these zymotic diseases ... istered last week in Derby; whereas they caused ... t death-rates in Bristol, Leeds, and Wolverhampto... ... atest mortality from measles occurred in Bristol, ... ds, and Wolverhampton; from scarlet fever, ... Salford, Bradford, and Sunderland; from whooping-... n Preston and Huddersfield; and from "fever," in ... ester, Preston, and Plymouth. The 37 deaths from diphtheria in the twenty-eight towns included 16 in London, 6 in Portsmouth, 3 in Birmingham, and 4 in Liverpool. Small-pox caused one death in London, but none in its outer ring, or in any of the twenty-seven large provincial towns. Only one case of small-pox was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had increased in the six preceding weeks from 293 to 494, declined again last week to 415, and were 114 below the corrected weekly average. The causes of 99 ... per cent., of the deaths in the ... -eight towns ... eek were not certified either by a registered medical practitioner ... by a coroner. All the causes of death were duly certified in Plymouth, Birkenhead, and Huddersfield. The largest proportions of uncertified deaths were registered in Derby, Halifax, Blackburn, Oldham, and Salford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·1 and 22·0 per 1000 in the preceding two weeks, rose again to 22·5 in the week ending Dec. ...th; this rate was 1·8 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 16·3 and 18·0 in Leith and Perth, to ... in Glasgow and Paisley. The 556 deaths in the eight towns last week showed an increase of 12 upon the number in the previous week, and included 19 which were referred to whooping-cough, 16 to scarlet fever, 12 to diarrhœa, 11 to "fever" (typhus, enteric, or simple), 10 to measles, 6 to diphtheria, and 1 to small-pox; in all, 75 deaths resulted from these principal zymotic diseases, against 81 and 63 in the preceding two weeks. These 75 deaths were equal to an annual rate of 3·0 per 1000, which exceeded by 0·8 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 19 and 15 in the previous two weeks, rose again last week to 19, of which no fewer than 16 occurred in Glasgow. The 16 deaths from scarlet fever showed a further decline from the 25 and 17 returned in the previous two weeks, and included 10 in Glasgow and 2 in Edinburgh. The 12 deaths attributed to diarrhœa (of which 7 occurred in Glasgow, 3 in Aberdeen, and 2 in Perth) showed a further decline from the numbers in recent weeks. The 11 deaths referred to "fever," however, showed a considerable increase upon recent weekly numbers, and included 8 in Glasgow, against but 2 in each of the preceding two weeks. All the 10 fatal cases of measles, exceeding the numbers in recent weeks, were returned in Glasgow; while of the 6 deaths from diphtheria, 4 occurred in Glasgow and 2 in Edinburgh. The death from small-pox ... registered in Aberdeen. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 125, 142, and 144 in the preceding three weeks, further rose last week to 174, but were 1 below the number in the corresponding week of last year. The causes of 57, or more than 10 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had increased in the preceding five weeks from 23·6 to 35·6, declined again to 29·6 in the week ending Dec. 18th. During the first eleven weeks of the current quarter the death-rate in the city averaged 25·5; the mean rate during the same period did not exceed 18·2 in London and 18·9 in Edinburgh. The 200 deaths in Dublin last week showed a decline of 41 from the

high number in the previous w… which were referred to "fever" (typhus… 5 to scarlet fever, 5 to diarrhœa, 2 to … 1 to measles, and not one either to sma… eria. Thus 22 deaths resulted from these princip… eases, against 21 and 23 in the previous two … were equal to an annual rate of 3·3 per 1000, the … the same diseases being but 1·7 in London and 1… urgh. The 9 deaths from "fever" showed a mark… e upon those returned in recent weeks, and excee… uber in any week since the middle of Februa… fatal cases, however, of scarlet fever, diarrh… ping-cough were all fewer than those retur… previous week. Four inquest cases and 2 deaths … ence were registered; and 41, or nearly a quarter, of t… ths occurred in public institutions. The deaths of in… exceeded the number in any recent week, while those o… lderly persons showed a decline. The causes of 48, or 24… r cent., of the deaths registered during the week were not … rtified.

INFANT MORTALITY IN EGYPT.

The excessive mortality of infants and young children in Egypt, and especially in its largest towns, has recently been the subject of a special report by M. Engel, the medical superint… of sanitary statistics, to the Inspector-General … blic Health in … ntry. It is pointed out that in Cairo the proportion of deaths under five years of age to total deaths was equal to 55·6 per cent. in Cairo, and to 52·2 per cent. in the three years 1882, 1884, and 1885. The political condition of the country broke the continuity of the statistics in 1883. In the fourteen largest towns of Lower Egypt the proportion was equal to 55·7 in the first and to 64·1 in the second quarters of the present year. These figures point conclusively to marked excesses of infant mortality, but the proportion of deaths of children to total deaths depends in great measure upon the proportion of children in the living population, which M. Engel has no means of ascertaining; and the high birth-rate in Egypt is a well-known fact. In o… , therefore, to measure infant mortality by a more sa… ctory standard, the proportion of these deaths to … orded births is also given. The mean proportion of deaths under one year to births in the last three years in Cairo was 31·4 per cent., and in four towns of Lower Egypt (Rosetta, Chibin-el-Kom, Guizet, and Benha) 26·8 per cent.; in Alexandria infant mortality, measured in this way was 21·5 in 1884 and 21·0 in 1885. Infant mortality, measured in this manner, did not exceed 15·1 per cent. in London during the ten years 1875-84, and during last year it was only 14·8; on the other hand, it must be remembered that in the five years 1870-4 this proportion of infant mortality was equal to 23·9 in Liverpool, whereas it fell to 18·8 in 1874-84. It is stated that the Egyptians show great affection for their children, but that only an insignificant proportion of them secure any medical attention in case of illness. M. Engel reports that in the smaller Egyptian towns not more than 1 per cent. of the deceased persons of all ages have been seen by a medical practitioner previous to death. Under these circumstances, and bearing in mind the fatal effect of the climate upon young children, the high rate of infant mortality in Egypt need cause no surprise.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Gen… Sir Anthony Dickson Home, V.C., K.C.B., has been granted retired pay.

INDIA OFFICE.—The Queen has approved of the following promotions among the officers of the Staff Corps and Indian Military Forces made by the Governments in India:—Deputy Surgeon-General George Bidie, C.I.E., of the Madras Medical Establishment, to be Surgeon-General; Surgeon-Major Geo. Cochet Cheanaye, Surgeon-Major John Duncan, M.D., and Surgeon-Major Edward Ord-Tandy, of the Bengal Medical Establishment, and Surgeon-Major Alexander Porter, M.D., and Surgeon-Major Samuel Bradshaw Hunt, of the Madras Medical Establishment, to be Brigade Surgeons; Surgeon Richard Nugent Stoker, Surgeon Gerald Bomford, M.D., Surgeon Arthur Barclay, and Surgeon Charles Joseph McCartie, M.D., of the Bengal Medical Establishment; Surgeon William O'Hara and Surgeon Thomas … of the Madras Medical Establishment, and Surgeon Dhanjiaba Navroji Parakh and Surgeon John Lucas, M.D., of the Bombay Medical Establishment, to be Surgeons-Major.

ARTILLERY VOLUNTEERS.—2nd Middlesex: James Hill Gibson, M.D., to be Acting Surgeon.

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the King's Own Light Infantry (South Yorkshire Regiment): Acting Surgeon F. H. Wood resigns his appointment.

DISLOCATION OF THE HIP.

To the Editor of THE LANCET.

SIR,—In his remarks last week on my lecture on "Dislocation of the Hip" (THE LANCET, Nov. 27th), Mr. Morris confesses his inability to understand one of my conclusions, for he says, "I do not know how a dislocation can be other than *indirect* if the head of the bone is '*carried up to a variable extent*,' no matter by what force, *after it has left the acetabulum*." To which I must reply that I confess my inability to understand the difficulty. If the head of the bone is driven in one direction through the capsule onwards from the acetabulum, it is, I suppose, a direct dislocation, however variable may be the extent to which it is driven; and this is what I maintain occurs in many, at any rate, of the so-called backward dislocations of the hip. Force applied at the lower part of the thigh and knee, with the limb flexed, *ad*ducted, and inverted, drives the head of the thigh-bone through the lower and back part of the capsule between the obturator muscles to the back of the joint, or backwards and upwards, to an extent and in a direction varying with the amount and direction of the force. This, as I have said, may be shown in the dead body. Or, owing to somewhat more obliquity in the direction of the force, the head of the bone may be driven through the capsule at a correspondingly higher level under the obturator internus, tearing through that muscle with the gemellus superior, and coming into contact with, and perhaps tearing also, the pyriformis, and, it may be, one or more of the glutei. In these cases the course taken by the bone is in one direction, and is the resultant of force acting in one direction; though the course taken and the extent to which the head of the bone goes will, in different cases, vary according to variations in the line of action of the force and the a… the force. The bone may be driven directly, back… upwards, through any part of the back of the caps… the middle, or upper part. Most commonly it a… under part of the back of the capsule whi… position of the limb—flexion, *ad*-duc… usual or natural one, one of har-m… therefore in which the limb is … hock occurs, which cannot be … rsion.
